

6 Herring in the Celtic Sea (divisions 7.a South of 52°30'N and 7.g, 7.h and 7.j)

The assessment year for this stock runs from 1 April until 31 March. Unless otherwise stated, year and year class are referred to by the first year in the season i.e. 2018 refers to the 2018–2019 season.

The WG notes that the use of “age”, “winter rings”, “rings” and “ringers” still causes confusion outside the group (and sometimes even among WG members). The WG tries to avoid this by consequently using “rings”, “ringers”, “winter ringers” or “wr” instead of “age” throughout the report. However, if the word “age” is used it is qualified in brackets with one of the ring designations. It should be observed that, for autumn and winter spawning stocks such as this one, there is a difference of one year between “age” and “rings”. Further elaboration on the rationale behind this, specific to each stock, can be found in the individual Stock Annexes. It is the responsibility of any user of age based data for any of these herring stocks to consult the relevant annex and if in doubt consult a relevant member of the Working Group.

6.1 The Fishery

6.1.1 Advice and management applicable to 2018–2019

The TAC is set by calendar year and in 2018 was 10 127 t (agreed by the Council of the European Union, based on the long-term management plan). The TAC for 2019 is 4742 t (based on the ICES MSY approach).

Long-Term Management Plan

A long-term management plan has been proposed by the Pelagic RAC. The most recent evaluation of this plan took place in 2018.

ICES advises that the harvest control rule in the long-term management plan for Celtic Sea herring is no longer consistent with the precautionary approach. The management plan results in a greater than 5% probability of the stock falling below B_{lim} in several years throughout the 20 year simulated period. The simulations indicate the management plan cannot ensure that the stock is fished and maintained at levels which can produce maximum sustainable yield as soon as or by 2020.

6.1.2 The fishery in 2018–2019

In 2018 the Irish fishery took place in 7.g in Q3 and in 7.g and 7.a.S in Q4.

The Netherlands reported catches of just over 400 t coming from 7.g and 7.h, Germany, France and the UK did not utilize their quota. 7.h is part of the management area, but it is unclear if it is part of the stock area.

The spatial distribution of the 2018 landings is presented in Figure 6.1.2.1. There was not full quota uptake in 2018.

The estimated catches from 1988–2018 for the combined areas by quota year and by assessment year (1 April–31 March) are given in tables 6.1.2.1 and 6.1.2.2 respectively. The catch taken during the 2018–2019 season decreased to about 4400 t (Figure 6.1.2.2).

The catch data include discards in the directed fishery until 1997. An independent observer study of the Celtic Sea herring fishery was conducted annually from 2012 to 2017. This observer programme was discontinued in 2018. Discards from these trips were raised to the total international catch using a weighted average for each year from 2012 to 2017.

Regulations and their effects

Under the previous rebuilding plan, the closure of Subdivision 7.aS from the 2007-present, except for a sentinel fishery, meant that only small dry hold vessels, no more than 50 feet total length, could fish in that area. In 2012 local quota management arrangements were adopted to restrict fishing in 7.aS to vessels under 50 feet, but the total quota allocation increased from 8% to 11%. Therefore, from 2012 there was a slight increase in landings from this area. There is evidence that closure of Subdivision 7.aS under the rebuilding plan, helped to reduce fishing mortality (Clarke and Egan, 2017). The exact mechanisms for this are unclear.

6.1.3 Changes in fishing technology and fishing patterns

The fishery in the past number of years has changed compared to previous years. In recent years, herring have been found very close to the bottom in the main fishery, in the acoustic dead-zone of the echosounder, particularly offshore in Division 7.g. The fishery reports that herring are often not visible on echosounders at all. Tow duration has increased markedly because it takes longer to catch the desired quantity of herring. In 2017, the fishery was concentrated offshore initially, but effort shifted to more inshore areas in Division 7.g when herring became difficult to locate offshore. It was difficult for the Irish fleet to catch its quota in 2017. The fishery in 2018 was mainly concentrated inshore in 7.g with no significant offshore fishery. Irish vessels had difficulty catching the quota again in 2018.

Vessels greater than 50 feet total length are excluded from 7.aS under local Irish legislation. This has shifted effort onto The Smalls/Celtic Deep ground, south of the 52°N line, in an area which straddles the boundary between the Irish and UK exclusive economic zones (EEZs).

The increase in the TAC from 2010 attracted more Irish vessels, and some non-Irish vessels to fish this stock. Irish quota is allocated to vessels on a weekly basis. The large number of vessels involved has led to individual quotas being reduced. This initially led to increased discarding risk due to vessels being unable to catch their small allocations without extra-quota catches that are often slipped. However, in 2012, flexibility was introduced to the system, whereby a vessel could use some of the following week's quota to mitigate slippage.

6.1.4 Discarding

As in all pelagic fisheries, estimation of discarding is very difficult. Individual instances of discarding may be quite infrequent in occurrence. However individual slippages could result in considerable quantities of herring being discarded. The estimates produced by the HAWG in 2012 provided a sensitivity analysis of the assessment to maximum possible discarding. The risk of discarding (slippage induced by restrictive vessel quotas) is now reduced, due to the flexibility mechanism introduced in quota allocation since 2012. Available evidence is that the discard rate is negligible in directed fisheries. The Marine Institute carried out four herring directed discard trips in 2018 with no discarding observed.

Estimates of discarding from observer trips for the purposes of marine mammal bycatch studies, reported 1% discarding in 2012, 0.8% in 2013 (McKeogh and Berrow, 2013), 3.4% in 2014 (McKeogh and Berrow, 2014), 1.4% in 2015 in the main fishery and 1.5% in the 7.aS small boat fishery (Pinfield and Berrow, 2015), 1.13% in 2016 (O'Dwyer *et al.*, 2016) and 1.19% in 2017

(O'Dwyer and Berrow, 2017). This observer programme was discontinued in 2018 and no discard estimates were available.

Since 2015, this stock is covered by the landings obligation.

6.2 Biological composition of the catch

6.2.1 Catches in numbers-at-age

Catch numbers-at-age are available for the period 1958 to 2018. Three winter ring fish were the main age class in 2018, followed by 2- and 4-wr respectively (Table 6.2.1.1). The yearly mean standardized catch numbers-at-age are shown in Figure 6.2.1.1. Older ages (8 and 9 wr) are present in very small numbers in 2018. Truncation of ages is again evident in this stock.

The overall proportions-at-age in the catch and the survey are presented in Figure 6.2.1.2. There is generally good agreement between the data sources. The Q4 acoustic survey picks up 1-wr fish in larger proportions than the catch data in some years including 2018. The catch and survey data both show a peak in three winter ring fish in 2018. These samples were taken inshore and are comprised mainly of younger fish.

Length–frequency data by division and quarter are presented in Table 6.2.1.2. The greatest length range was found in 7.g Q4. The fishery here took place inshore and smaller fish were encountered here.

6.2.2 Quality of catch and biological data

Biological sampling of the catches was carried out in the area exploited by the Irish fishery (Table 6.2.2.1) in 2018. Under the Data Collection Framework the sampling of this stock is well above that required by the Minimum Programme (Section 1.5).

6.3 Fishery-Independent Information

6.3.1 Acoustic Surveys

The Celtic Sea herring acoustic survey (CSHAS) time-series currently used in the assessment runs from 2002 to 2018, excluding 2004 and 2017. The full survey time-series is presented in Table 6.3.1.1. The internal consistency between ages 1–9 from the acoustic survey is presented in Figure 6.3.1.4.

The acoustic survey of the 2018–2019 season was carried out from 8 to 28 October 2018, on the Celtic Explorer <http://hdl.handle.net/10793/1385> (O'Donnell *et al.*, 2018). Survey effort for the core area consisted of 2311 nautical miles of transects for acoustic integration and the geographical coverage was 19 347 square nautical miles. The three adaptive surveys accounted for 459 nautical miles of transects covering an area of 3304 square nautical miles. The acoustic survey track is shown in Figure 6.3.1.1.

The 2018 survey consisted of replicate surveys (two broad-scale, and three adaptive mini-surveys) covering the same area. The highest biomass estimate from the broad-scale surveys was used to estimate numbers-at-age for the assessment (i.e. Pass 1 in 2018). NASC distribution plots from the broad-scale survey are presented in Figure 6.3.1.2 and from the adaptive mini survey in Figure 6.3.1.3. Herring TSB (total-stock biomass) and abundance (TSN) estimates from the 2018 survey were 9788 t and 213 491 individuals respectively.

A total of 15 trawl hauls were carried out during the survey in 2018, with four hauls containing >50% herring by weight of catch. All hauls contained some herring. A total of 529 herring were aged from survey samples in addition to 1668 length measurements and 807 length–weights recorded. Herring age samples ranged from 0–8 winter-rings.

Immature 0-group herring were observed across the survey area, appearing in every haul in small numbers. The presence of this year class was reported further east toward the UK coast by the RV Cefas Endeavour as part of the PELTIC survey program that takes place at the same time (J. Vanderkooij, pers. comm.). Overall, the contribution of 0-group herring accounts for over 51% of the total stock abundance for the Pass 1 estimate. This signal is encouraging as a potential source of recruitment in a period of low stock abundance and persistent poor recruitment.

The contribution of 1-winter ring fish from around the Cork Harbour area is an annual occurrence in low background numbers. In 2018, this age group represents a significant contribution to the overall biomass (31.7% of TSB and 26.1% of TSN). It is important to note that this proportion is relative to the low contribution of other age classes in the overall low abundance estimate and not a sign of a stronger than normal year class for this cohort.

The spawning-stock-biomass (SSB) estimate in 2018 represents one of the lowest SSB points in the current time-series. The absence of the offshore migratory component of the stock within the wider survey area cannot be attributed to containment as good area coverage was attained.

WGIPS have highlighted in recent years that herring are frequently distributed close to the bottom, within the acoustic dead-zone of the echosounder and therefore it is difficult to accurately estimate the biomass in the survey area. This behaviour was not observed in 2018 and there were no herring observed offshore in the survey.

In 2018 the Western European Shelf Pelagic Acoustic Survey (WESPAS) directed at boarfish, horse mackerel and herring on the Malin Shelf, also had some coverage in the Celtic Sea. An abundance estimate for Celtic Sea herring was calculated for this survey in 2018 <http://hdl.handle.net/10793/1380> but cannot be used for stock assessment purposes. This survey will continue in 2019 and methods will be further refined to increase the precision of future estimates. This survey has the potential to be used as an index for the Celtic Sea herring stock when a sufficient time-series of data becomes available.

6.4 Mean weights-at-age and maturity-at-age and Natural Mortality

The mean weights in the catch and mean weights in the stock at spawning time are presented in Figure 6.4.1.1 and Figure 6.4.1.2 respectively. There has been an overall downward trend in mean weights-at-age in the catch since the mid-1980s. After a slight increase around 2008, they have declined again. In 2018 slight increases in mean weights at some ages can be seen. Mean weights in the stock at spawning time were calculated from biological samples from the Q4 (Figure 6.4.1.2). The overall trends in stock weights are as in the catch weights.

In the assessment, 50% of 1-wr fish are considered mature. Sampling data from the Celtic Sea catches suggest that greater than 50% of 1-wr fish are mature (Lynch, 2011). However, the 2014 benchmark (ICES, 2014) concluded that there was insufficient information to change the maturity ogive.

Following the final procedure of ICES, HAWG 2015, natural mortality values used in the final assessment incorporated the SMS run as obtained in 2011.

The time-invariant natural mortalities and maturities-at-age are presented in the text table below.

	1	2	3	4	5	6	7	8	9+
Maturity	0.5	1	1	1	1	1	1	1	1
Natural mortality	0.767	0.385	0.356	0.339	0.319	0.314	0.307	0.307	0.307

6.5 Recruitment

At present there are no independent recruitment estimates for this stock.

6.6 Assessment

This stock was benchmarked in 2015 by WKWEST (ICES, 2015) and inter-benchmarked by WKPELA 2018.

6.6.1 Stock Assessment

This update assessment was carried out using ASAP. The assessment was tuned using the Celtic Sea herring acoustic survey (CSHAS) ages 2–7 winter ring and excluding the 2017 survey. The input data are presented in tables 6.6.1.1 and 6.6.1.2. The ASAP settings are as per the 2018 inter-benchmark and are presented in (Table 6.6.1.3). The stock summary is presented in Table 6.6.1.4.

Figure 6.6.1.1 shows the catch proportions-at-age residuals. The residuals are large for the young ages, which is to be expected because these are estimated with low precision. Larger residuals can be seen in recent years. Overall there are no clear patterns in the residuals. Figure 6.6.1.2 shows the observed and predicted catches. In general, the model followed the observed catches quite closely. The observed and predicted catch proportions-at-age are shown in Figure 6.6.1.3. There is some divergence in the most recent year, most notable at 3 wr with a larger proportion observed than predicted. Overall the fits are good throughout the full time-series.

The selection pattern in the fishery for the final assessment run is shown in Figure 6.6.1.4. Selection is fixed at 1 for 3-wr which is the age that Celtic Sea herring are considered to be fully selected. Selection at all other ages is estimated by the model. This gives a dome-shaped selection pattern which is considered appropriate to this fishery. The model predicts a drop in selection at-age 9-wr. This may be the case given the lesser abundance of 9-wr in the catch data.

Figure 6.6.1.5 shows the residuals of the index proportions-at-age. The largest residuals can be seen at the younger ages. The index fit shows generally good agreement with the exception of the very large survey index in 2012 (Figure 6.6.1.6). The selectivity parameters were adjusted at the inter-benchmark. Selection is now fixed for ages 3–5. This gives a more dome-shaped selection pattern with selection declining at older ages (Figure 6.6.1.7).

The analytical retrospective from ASAP is shown in Figure 6.6.1.8. The Mohn’s Rho on SSB (Mohn, 1999) is calculated as -0.17 over a five-year peel. This is a slight increase on the 2018 assessment where the Mohns Rho on SSB was -0.12.

Figure 6.6.1.9 shows uncertainties over time in the assessment estimates. The greatest uncertainty is seen with the estimates of recruitment. This may be related to the lack of a fisheries-independent estimate of recruitment.

State of the stock

The stock summary plots from the final assessment in 2018 and the update ASAP assessment in 2019 are presented in Figure 6.6.1.10 and the stock summary in Table 6.6.1.4. The assessment shows SSB is declining and is estimated to be 22 977 t in 2018. The stock is currently below B_{pa} and B_{lim} .

Mean F (2–5 ring) in 2018 is estimated as being 0.33, which is a decrease from 2017 when F was 0.64. F is above F_{pa} and F_{MSY} and just below F_{lim} . Recruitment was good for several years with strong cohorts in 2005, 2007, 2009, 2010, 2011, and 2012 having entered the stock. Recruitment has been lower in recent years and has been below the long-term average since 2013.

6.7 Short-term projections

6.7.1 Deterministic Short-Term Projections

An updated procedure for STF was performed, using the procedure agreed at the 2014 benchmark (ICES 2014/ACOM 43). The 2019 short-term forecast follows the benchmark procedures.

Recruitment (final year, interim year and advice year) in the short-term forecast is to be set to the same value based on the segmented stock–recruit relationship, based on the SSB in the forecast year - 2 (2017). As this SSB value (21 999 t) is below the change-point (47 575 t), the following adjustment is applied.

Recruitment (forecast year) = plateau recruitment * (SSB forecast year -2) / SSB Changepoint)

Recruitment 2019 = 441 902 * (21 999/47 575) = 204 340

Interim year catch was taken to be the TAC, plus carryover on the national quotas. Non-Irish intermediate year catches were further adjusted based on recent quota uptake. The intermediate year catch was estimated as 5320 t.

A deterministic short-term forecast was performed using in FLR. The input data are presented in Table 6.7.1.1.

The results of the short-term projection are presented in Table 6.7.1.2. Fishing in accordance with the MSY approach implies a zero catch in 2020.

6.7.2 Multiannual short-term forecasts

No multiannual simulations were conducted in 2019.

6.7.3 Yield-per-recruit

No yield-per-recruit analyses were conducted in 2019.

6.8 Long-term simulations

Long-term simulations were carried out as part of the ICES evaluation of the long-term management plan for Celtic Sea herring. ICES advises that the harvest control rule is no longer consistent with the precautionary approach. The management plan results in a greater than 5% probability of the stock falling below B_{lim} in several years throughout the 20 year simulated period. The simulations indicate the management plan cannot ensure that the stock is fished and maintained at levels which can produce maximum sustainable yield as soon as or by 2020. The long-term management plan is no longer used to give advice for this stock.

Further simulations are currently being conducted as part of the development of a rebuilding plan for this stock. Harvest control rules with different F values and constant catch options are being explored using the SimpSIM simulation package.

6.9 Precautionary and yield-based reference points

Reference points were re-estimated by WKPELA 2018.

Framework	Reference point	Value	Technical basis	Source
MSY approach	MSY B_{trigger}	54 000 t	B_{pa}	ICES (2018a)
	F_{MSY}	0.26	Stochastic simulations using segmented regression stock–recruitment relationship from 1970–2014	ICES (2018a)
Precautionary approach	B_{lim}	34 000 t	B_{loss} = the lowest observed SSB (1980)	ICES (2018a)
	B_{pa}	54 000 t	$B_{\text{pa}} = B_{\text{lim}} \times \exp(1.645 \times \sigma B)$, with $\sigma B = 0.29$.	ICES (2018a)
	F_{lim}	0.45	Equilibrium F maintaining SSB > B_{lim} with 50% probability	ICES (2018a)
	F_{pa}	0.27	$F_{\text{pa}} = F_{\text{lim}} \times \exp(-1.645 \times \sigma F)$, where $\sigma F = 0.30$ from assessment uncertainty (capped) in the terminal year	ICES (2018a)

6.10 Quality of the Assessment

Figure 6.6.1.9 shows uncertainties over time in the assessment estimates. The uncertainties for the key parameters (SSB, recruitment and F) are between 0.1 and 0.3 for the majority of the time-series; uncertainties have increased in the final years. Recruitment estimates in the final year show the highest uncertainty.

The SSB and F values based on the assessment and forecast in 2018 are compared with the assessment outputs in 2019 and are shown in the text table below. The assessment in 2019 shows a more pessimistic outlook for this stock with SSB revised downwards and F revised upwards. This can also be seen in the historical retrospective plot in Figure 6.10.1

2018 Assessment				2019 Assessment				% change in the estimates	
Year	SSB	Catch	F 2-5	Year	SSB	Catch	F 2-5	SSB	F 2-5
2016	46734	16,318	0.41	2016	35398	16318	0.58	-24%	42%
2017	35738	10767	0.41	2017	21999	10767	0.64	-38%	56%
2018*	36139	10,887	0.44	2018	22977	4418	0.33	-36%	-24%

* from intermediate year in STF.

The 2018 acoustic survey estimate is the lowest in the current time-series. The survey time-series used in the assessment includes data from 2002 to 2018 (no survey in 2014 and the 2017 survey excluded). Since 2014, herring have been observed close to the bottom, and less reliably estimated by the acoustic survey.

Estimates of recruitment are uncertain and this may be related to the lack of a fisheries-independent recruitment estimator. In the Irish Sea, mixing occurs between juvenile winter spawned Celtic Sea fish and autumn spawned Irish Sea fish but the level of mixing is unquantified.

6.11 Management Considerations

The stock has declined substantially from a high in 2012, as older cohorts have moved through the fishery. Recruitment has been below average since 2013. The stock is currently forecast to be below B_{lim} in 2019. Fishing is currently above F_{MSY} of 0.26.

The advice provided for this stock for 2020 is based on the ICES MSY approach. The basis for the advice is the same as previous years. The TAC however was set according to the long-term management plan from 2012–2018. Evaluations conducted in 2018 found that the long-term management plan is no longer precautionary (ICES, 2018). A rebuilding plan is currently being developed for this stock.

A change in fish behaviour has been observed by the acoustic survey since 2014. The fish have been observed close to the bottom and have been difficult to detect acoustically.

The closure of the Subdivision 7.aS as a measure to protect first time spawners has been in place since 2007–2008, with limited fishing allowed. Currently only vessels of no more than 50 feet in registered length are permitted to fish in this area. A maximum catch limitation of 11% of the Irish quota is allocated to this fishery.

6.12 Ecosystem considerations

Herring are an important prey species in the ecosystem and also one of the dominant planktivorous fish.

The spawning grounds for herring in the Celtic Sea are well known and are located close to the coast (O'Sullivan *et al.*, 2013). These spawning grounds may contain one or more spawning beds on which herring deposit their eggs. Individual spawning beds within the spawning grounds have been mapped and consist of either gravel or flat stone (Breslin, 1998). Spawning grounds tend to be vulnerable to anthropogenic influences such as dredging, sand and gravel extraction, dumping of dredge spoil and waste from fish cages. There have been several proposals for extraction of gravel and to dump dredge spoil in recent years. Many of these proposals relate to known herring spawning grounds. ICES have consistently advised that activities that perturb herring spawning grounds should be avoided.

Herring fisheries are considered to be clean with little bycatch of other fish. Mega-fauna bycatch is unquantified, though anecdotal reports suggest that seals, blue sharks, tunas, and whitefish are caught from time to time. In the 2017 observer study of the Celtic Sea herring fishery, whiting was the most frequently recorded bycatch species followed by haddock and mackerel. No marine mammals or seabirds were recorded as bycatch in the fishery, with only one elasmobranch (an unidentified dogfish species) recorded. A total of 26 marine mammal sightings were recorded during observer trips (O'Dwyer and Berrow, 2017).

6.13 Changes in the environment

Weights in the catch and in the stock at spawning time have shown fluctuations over time (Figures 6.4.4.1 and 6.4.1.2), but with a decline to lowest observations in the series at the end. The declines in mean weights are a cause for concern, because of their impact on yield and yield-per-recruit. Harma (unpublished) and Lyashevskaya *et al.* (in prep) found that global environmental

factors, reflecting recent temperature increases (AMO and ice extent) were linked to changes in the size characteristics during the 1970s–1980s. Outside this period, size-at-age patterns were correlated with more local factors (SST, salinity, trophic and fishery-related indicators). Generally, length-at-age was mostly correlated with global temperature-related indices (AMO and Ice), and weight was linked to local temperature variables (SST). There was no evidence of density-dependent growth in the Celtic Sea herring population, which is in accordance with previous studies (Molloy, 1984; Brunel and Dickey-Collas, 2010; Lynch, 2011). Rather, stock size exhibited a positive relationship with long-term size-at-age of Celtic Sea herring (Harma, unpublished).

In the Celtic Sea, a change towards spawning taking place later in the season has been documented by Harma *et al.* (2013). The causes of this are likely to be environmental, though to date they have not been elucidated (Harma *et al.*, 2013). It should be noted that declines in mean weights, examined by Harma *et al.* (2013) are not explained by the relative contribution of heavier at-age autumn spawners. Rather, both autumn and winter spawners experienced concurrent declines in mean weights in recent years.

A shift towards later spawning has also been reported by local fishers in this area. WKWEST received a submission from the Celtic Sea Herring Management Advisory Committee of substantial spawning aggregations in Division 7.j in January 2015. This area is mainly an autumn spawning area (O’Sullivan *et al.*, 2012).

Analyses of productivity changes over time in European herring stocks was examined by ICES, HAWG (2006). It was found that this stock was the only one not to experience a change in productivity or so-called regime shift. This is also seen in the Surplus production per unit stock biomass using information from the 2013 assessment. Evidence from the new ASAP assessment, in terms of recruits per spawner, does not alter this perception (ICES, WKWEST 2015).

Table 6.1.2.1. Herring in the Celtic Sea. Landings by quota year (t), 1988–2018. (Data provided by Working Group members). These figures may not in all cases correspond to the official statistics and cannot be used for management purposes.

Year	France	Germany	Ireland	Netherlands	UK	Unallocated	Discards	Total
1988	-	-	16 800	-	-	-	2400	19 200
1989	+	-	16 000	1900	-	1300	3500	22 700
1990	+	-	15 800	1000	200	700	2500	20 200
1991	+	100	19 400	1600	-	600	1900	23 600
1992	500	-	18 000	100	+	2300	2100	23 000
1993	-	-	19 000	1300	+	-1100	1900	21 100
1994	+	200	17 400	1300	+	-1500	1700	19 100
1995	200	200	18 000	100	+	-200	700	19 000
1996	1000	0	18 600	1000	-	-1800	3000	21 800
1997	1300	0	18 000	1400	-	-2600	700	18 800
1998	+	-	19 300	1200	-	-200	-	20 300
1999		200	17 900	1300	+	-1300	-	18 100

Table 6.2.2.1. Herring in the Celtic Sea. Sampling intensity of commercial catches (2018–2019). Only Ireland provides samples of this stock.

Division	Year	Quarter	Catch (t)	No. Samples	No. Measured	No. aged	Aged/1000 t
7.g	2018	3	311	0			
7.g	2018	4	2787	11	2531	549	197
7.aS	2018	4	884	1	50	50	57
Total	2018		3982	12	2581	599	150

Table 6.3.1.1. Herring in the Celtic Sea. Revised acoustic index of abundance used in the assessment. Total stock numbers-at-age (10^6) estimated using combined acoustic surveys (age refers in winter rings, biomass and SSB in 000's tonnes). 2–7 ring abundances are used in tuning. There was no survey in 2004. The survey in 2017 (shaded) was excluded; it was not recommended for tuning by HAWG in 2018; the single biological sample of herring obtained on the survey in 2017 was considered not adequate.

Table 6.6.1.3. Herring in the Celtic Sea. ASAP final Run settings.

Discards Included	No
Use likelihood constant	No
Mean F (Fbar) age (wr)range	2–5
Number of selectivity blocks	1
Fleet selectivity	By Age: 1–9-wr: 0.3,0.5,1,1,1,1,1,1,1 Fixed at-age 3-wr
Index units	2 (numbers)
Index month	October (10)
Index selectivity linked to fleet	-1 (not linked)
Index Years	2002–2018 (no survey in 2004 and 2017 not included)
Index age (wr)range	2–7
Index Selectivity	0.8,1,1,1,1,1 Fixed from ages 3–5-wr
Index CV	0.5 all years
Sample size	No of herring samples collected per survey
Phase for F-Mult in 1st year	1
Phase for F-Mult deviations	2
Phase for recruitment deviations	3
Phase for N in 1st Year	1
Phase for catchability in 1st Year	1
Phase for catchability deviations	-5
Phase for Stock recruit relationship	1
Phase for steepness -	-5 (Do not fit stock–recruitment curve)
Recruitment CV by year	1
Lambdas by index	1
Lambda for total catch in weight by fleet	1
Catch total CV	0.2 for all years
Catch effective sample size	No of samples from Irish sampling programme. Downweighted to 5 in 2015, 2016, 2017 and 2018
Lambda for F-Mult in 1st year	0 (freely estimated)
CV for F mult in the first year	0.5
Lambda for F-Mult deviations	0 (freely estimated)

CV for f mult deviations by fleet	0.5
Lambda for N in 1st year deviations	0 (freely estimated)
CV for N in the 1st year deviations	1
Lambda for recruitment deviations	1
Lambda for catchability in 1st year index	0
CV for catchability in 1st year by index	1
Lambda for catchability deviations	0
CV for catchability deviations	1
Lambda for deviation from initial steepness	0
CV for deviation from initial steepness	1
Lambda for deviation from unexplained stock size	0
CV for deviation from unexplained stock size	1
