

12 Sprat in the Celtic Seas (Subarea 6 and divisions 7.a-c and 7.f-k)

Most sprat fisheries in the Celtic Seas area are sporadic and occur in different places at different times. Separate fisheries have taken place in the Minch, and the Firth of Clyde (6.aN); in Donegal Bay (6.aS); Galway Bay and in the Shannon Estuary (7.b); in various bays in 7.j; in 7.aS; in the Irish Sea. A map of these areas is provided in Figure 12.1.

The stock structure of sprat populations in this ecoregion is not clear. In 2014, HAWG presented an update of the available data on these sprat populations, in a single chapter. However, HAWG does not necessarily advocate that subareas 6 and 7 constitutes a management unit for sprat, and further work is required to resolve the problem.

12.1 The Fishery

12.1.1 ICES advice applicable for 2024 and 2025

ICES analysed data for sprat in the Celtic Sea and West of Scotland. Currently there is no TAC for sprat in these areas, and it is not clear whether there should be one or several management units. ICES stated that there is insufficient information to evaluate the status of sprat in this area. Therefore, when the precautionary approach is applied, ICES advises that catches should be no more than 2240 t in 2024 and 2025. The TAC for the English Channel (7.d and e) is the only one in place for sprat in this area.

12.1.2 Catches

The total sprat catches, by ICES Subdivision (where available) are provided in tables 12.1.1–12.1.7, with the total catches in Table 12.1.8, and in figures 12.2.1–12.2.8. Only Ireland and the United Kingdom (England and Wales) recorded catches from the stock in 2022, with Ireland taking the majority of the catches (Table 12.1.8).

12.1.3 Division 6.a (West of Scotland and Northwest of Ireland)

Catches have been dominated by UK-Scotland and Ireland (Table 12.1.1). The Scottish fisheries have taken place in both the Minch and in the Firth of Clyde. The Irish fishery has always been in Donegal Bay. Despite the wide separation of these areas, the trends in catches between the two countries are similar. Irish data may be underestimated, due to difficulties in quantifying the catches from vessels of less than 10 m length.

The Scottish fishery is mainly for human consumption and is typically a winter fishery taking place in November and December, occasionally continuing into January. Catches were high in the early part of the time-series, with two periods of intense fishing pressure where annual catches exceeded 10000 t in the period 1972 to 1978 (Figure 12.2.1) and again in the period 1995 to 2000. In 2005 to 2009, the fishery was virtually absent but has fluctuated greatly since 2010, with only 1 t taken in 2018 followed by 4575 t in 2019. A total of 1697 tonnes was taken in 2022, all by Ireland, with no Scottish catches in 2021 or 2022.

Division 7.a

The main historic fishery was by Irish boats, in the 1970s, in the western Irish Sea. This was an industrial fishery and catches were high throughout the 1970s, peaking at over 8000 t in 1978 (figures for 7.aN are presented in Table 12.1.2 and 7.aS presented in Table 12.1.3). The fishery came to an end in 1979, due to the closure of the fishmeal factory in the area. It is not known what proportion of the catch was made up of juvenile herring, though the fishing grounds were in the known herring nursery areas. In the late 1990s and early 2000s, UK vessels landed up to 500 t per year.

Irish Catches from 1950–1994 may be from 7.aN or 7.aS. Very high catches in 7.aS were reported in 2012 (Table 12.1.3) with a decrease in 2013 and only 16 t reported in 2014. In 2015 the catches increased to over 3500 t and dropped again to less than 1000 t in 2016. Despite the high catches registered in some years, those figures should be interpreted with caution because they may be overestimated. In 2020 catches from 7.aS were 6888 tonnes up from 2785 tonnes in 2019. Another 7861 t were landed in 2021 and 2026 t were landed in 2022. Irish catches from 7.aS are predominantly from Waterford Harbour (Table 12.1.3)

No catches from 7.aN were reported by Ireland in 2009–2013 or 2018 (Table 12.1.2), however there have been reported catches of 522 t in 2014, 771 t in 2015 and 150 t in 2016 and 2017. Irish catches in 2020 were 2521 tonnes up from 9 tonnes in 7.aN in 2019. Scotland reported less than a tonne of catches over 2021–2022 while Ireland took 381 tonnes in 2021 and 491 tonnes in 2022.

12.1.4 Divisions 7.b–c (West of Ireland)

Sporadic fisheries have taken place, mainly in Galway Bay and the Mouth of the river Shannon. The highest recorded catches were taken during the winter of 1980–1981, when over 5000 t were landed by Irish boats (Table 12.1.4, Figure 12.2.4) in Galway Bay (Department of Fisheries and Forestry, 1982). Since the early 1990s, catches fluctuated from very low levels to no more than 700 t per year in 2000. Zero catches were reported for 2016, increasing to above 500 tonnes in the two subsequent years. Irish catches were 1308 tonnes in 2020, 295 tonnes in 2021 and 197 tonnes in 2022. Irish data may be underestimated, due to difficulties in quantifying the catches from vessels of less than 10 m length.

12.1.5 Divisions 7.g–k (Celtic Sea)

Sprat catches in the Celtic Sea from 1985 onwards are WG estimates. In the Celtic Sea, Ireland has dominated catches. Patterns of Irish catches in divisions 7.g and 7.j are similar, though the 7.j catches have been higher. Catches for 7.g and 7.j were aggregated in this report. Catches have increased from low levels in the early 1990s, with catches fluctuating between 0 t in 1993 and just under 4200 t in 2005 (Table 12.1.7). The average catches in the last 10 years were equal to 3164 t. Irish catches increased to 5524 tonnes in 2021 and decreased to 2793 tonnes in 2022. Irish data may be underestimated, due to difficulties in quantifying the catches from vessels of less than 10 m length.

12.1.6 Fleets

Most sprat in the Celtic Seas Ecoregion are caught by small pelagic vessels that also target herring, mainly Irish, English and Scottish vessels. In Ireland, many polyvalent vessels target sprat on an opportunistic basis. At other times these boats target demersals and tuna, as well as other small pelagics. Targeted fishing takes place when there are known sprat abundances. However, the availability of herring quota is a confounding factor in the timing of a sprat-targeted fishery around Ireland.

Sprat may also be caught in mixed shoals with herring. The level of discarding is unknown, but based on a limited number of samples available to the working group this is estimated to be less than 1% of the catch.

In Ireland, larger sprats are sold for human consumption while smaller ones for fishmeal. Other countries mainly land catches for industrial purposes.

12.1.7 Regulations and their effects

There is a TAC for sprat for 7.d–e, English Channel. No other TACs or quotas for sprat exist in this ecoregion. Most sprat catches are taken in small-mesh fisheries for either human consumption or reduction to fishmeal and oil. It is not clear whether bycatches of herring in sprat fisheries in Irish and Scottish waters are subtracted from quota.

In 2019 the Irish government changed the regulation relating to the access of the inshore fishing grounds. The plan (Policy Directive No 1 of 2019) was that vessels >18 m LOA would not have access to the 6nm inshore zone from 1 January 2020. For vessels targeting sprat, an exemption from this regulation was in place to phase in this regulation gradually by 2022. However, the policy directive was subject to a protracted legal case and as of 2023 the Court of Appeal has quashed Policy Directive No 1 of 2019. Despite being quashed for 2023 onwards, the policy will have placed temporary restrictions on sprat fishing in the interim period 2020-2023.

12.1.8 Changes in fishing technology and fishing patterns

There is insufficient information available.

12.2 Biological Composition of the Catch

12.2.1 Catches by number and weight-at-age

There is no information on catches in number or weight in the catch for sprat in this ecoregion.

12.2.2 Biological sampling from the Scottish Fishery (6.a)

Between 1985 and 2002 the fishery was relatively well sampled and length and age data exists for this period with some gaps. Unfortunately, the data are not available electronically at the present time.

Sampling of sprat in 6.a came to an end in 2003 and no information on biological composition of catches exists in the period 2003–2011. Sampling was resumed in 2012 where a total of 8 catches were sampled. The sampling programme has been carried out since and it is anticipated that it will continue in the future.

12.3 Fishery-independent information

12.3.1 Celtic Sea Acoustic Survey (A4057)

The Irish Celtic Sea Herring Acoustic Survey (CSHAS) calculates an annual estimate of sprat biomass. Biomass estimates for Celtic Sea Sprat for the period November 1991 to October 2020 are shown in Figure 12.3.1 and Table 12.3.1. However, the survey results prior to 2002 are not comparable with the latter surveys because different survey designs were applied.

Since 2004 the survey has taken place each October in the Celtic Sea. Due to the lack of reliable 38 kHz data in 2010, no sprat abundance is available for this year.

It can be seen that there are large interannual variations in sprat abundance. Large sprat schools were notably missing in 2006, and so no biomass could be calculated. The utility of this survey as an index of sprat abundance should be considered carefully (Fallon *et al.*, 2012). Sprat is the second most abundant species observed from survey data. Sprat biomass over the time-series up to 2009 is highly variable, more so than could be accounted for by 'normal' inter survey variability (Table 12.3.1). The variability in the latter years is in part due to the behaviour of sprats in the Celtic Sea which are often seen in the highest numbers after the survey has ended in November/December and again in spring during spawning. The survey is placed to coincide with peak herring abundance and is temporally mismatched with what would be considered sprat peak abundance. The CSHAS survey design has changed over time and the survey primarily aims to quantify the nominal herring biomass. Any sprat biomass identified is incidental as it is not the target species, meaning the index will not be completely comparable between years. Survey trends should be interpreted with this in mind, and so should be perceived as a potential lower bound for the sprat abundance in the area.

2020 saw the lowest sprat biomass in the last decade, with each subsequent year showing an increase in biomass identified.

12.3.2 Scottish Acoustic Surveys (A9481)

A Clyde herring and sprat acoustic survey was carried out in June/July 1985–1990 and then discontinued (Figure 12.3.2 for coverage). Biomass estimates from all years as well as lengths and ages from some years are available from this survey but not presented here.

In 2012 this survey was reinstated as an October/November survey for herring mainly. Full results from these surveys for sprats are not available at the moment. Age and length distribution from the survey in 2012 are in Figure 12.3.4. In 2013 the survey was called off due to technical problems. The survey was resumed between 2012–2018. Total Biomass results from 2015 and 2018 are unavailable however data on the distribution of sprat in the Clyde are available for these years. These surveys were not conducted during the years 2019 – 2021.

12.3.3 DATRAS-hosted groundfish surveys

A number of groundfish surveys are carried out in the Celtic Seas ecoregion. These are freely available public datasets. Whilst these surveys do not target sprat, some sprat can be caught incidentally and may provide a coarse indication of sprat presence. The catchability is very low and it would not be meaningful to compare groundfish-derived biomass indices year-on-year for small pelagics (this is in contrast to acoustic surveys). Despite this, when records are considered across many months, multiple years and multiple surveys, presences can be confirmed. Figure 12.3.3 shows a presence map using these groundfish data, however it is important to interpret this in the context that the summed number is reflective of the amount of sampling effort.

12.3.4 Northern Ireland Groundfish Survey (G7144)

The Agri-Food and Biosciences Institute of Northern Ireland (AFBNI) groundfish survey of ICES Division 7.aN are carried out in March and October at standard stations between 53° 20'N and 54° 45'N (see Stock Annex for more detail on the survey). Sprat is routinely caught in the groundfish surveys however; data were not available at the time of submission of this report.

12.3.5 AFBI Acoustic Survey (A4075)

The Agri-Food and Biosciences Institute of Northern Ireland (AFBINI) carries out an annual acoustic survey in the Irish Sea each September (see the Stock Annex for a description of the survey).

The annual calculated sprat biomass from 1998–2022 is shown in Figure 12.3.5 and from 1994–2022 in Table 12.3.2. The biomass is estimated to have peaked in 2002 with 405 000 t and it declined to just under 95 000 t in 2010. This was followed by an increase with 2014 being the second highest estimate in the time-series, followed by a decline each year between 2016 and 2022, terminating at a new 15-year minimum in 2023. Spatial distribution of sprat at the time of the survey is shown in Figure 12.3.6. The AFBI survey is taken on a consistent annual survey grid, meaning the index is considered more comparable between years than the CSHAS survey index. Despite this, further work is required to investigate which populations the survey index applies to.

12.4 Mean weight-at-age and maturity-at-age

No data on mean weight-at-age or maturity-at-age in the catch are available.

12.5 Recruitment

The various groundfish and acoustic surveys may provide an index of sprat recruitment in this ecoregion. However further work is required.

12.6 Stock Assessment

There is currently no assessment for sprat in Subarea 6 and divisions 7.a-c and 7.f-k. The only assessment carried out in the Celtic Seas ecoregion is for sprat in 7.d-e and it is based on a survey index of biomass (Please refer to Section 12 - Sprat in divisions 7.d-e).

12.7 State of the Stock

The state of the sprat stock in the Celtic Seas is currently unknown and the data available are not enough to provide any indication on its status. There has been no change in advice this year. The precautionary buffer was applied in 2021 and therefore it is not applied in this advice period.

12.8 Short-term projections

No projections are presented for this stock.

12.9 Reference Points

No precautionary reference points are defined for sprat populations in the region.

12.10 Quality of the Assessment

The stock status is unknown and the Working Group does not have enough information to assess the status of the stock in relation to reference points.

Work to improve the information available for sprat in the Celtic Seas began with the Workshop on a Research Roadmap for Channel and Celtic Seas sprat (WKRRCCSS) and a second iteration of this workshop was scheduled to meet after HAWG in March 2023.

12.11 Management Considerations

Sprat is a short-lived species with large interannual fluctuations in stock biomass. The natural interannual variability of stock abundance, mainly driven by recruitment variability, is high and does not appear to be strongly influenced by the observed levels of fishing effort.

Sprat are mainly fished together with herring. The human consumption fishery only accounts for a minor proportion of the total catch. Within the current management regime, where there is a bycatch ceiling limitation of herring as well as bycatch percentage limits, the sprat fishery is controlled by these factors. Most management areas in this ecoregion do not have a quota for sprat. However, there is a quota in 7.d–e, English Channel, which has not been fully utilized.

12.12 Ecosystem Considerations

In the North Sea, multispecies investigations have demonstrated that sprat is one of the important prey species in the North Sea ecosystem for both fish and seabirds. At present, there are no data available on the total amount of sprat, and in general of other pelagic species, taken by seabirds in the Celtic Seas Ecoregion.

The Celtic Seas Ecoregion is a feeding ground for several species of large baleen whales (O'Donnell *et al.*, 2004–2009). These whales feed primarily on sprat and herring from September to February.

12.13 Tables and Figures

Table 12.1.1 Sprat in the Celtic Seas Ecoregion. Catches of sprat, 1985–2022, Division 6.a. Irish data may be underestimated, due to difficulties in quantifying the catches from vessels of less than 10 m length. (tonnes)

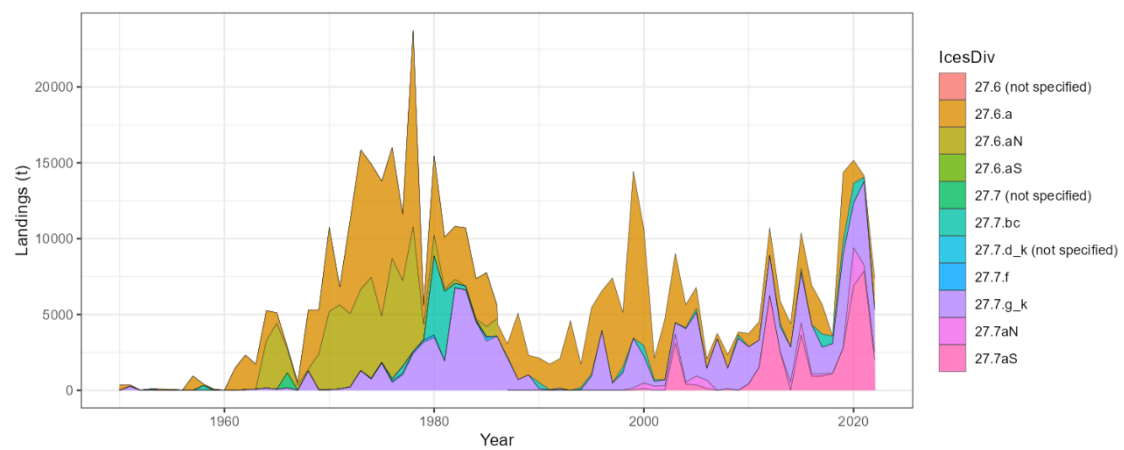

Figure 12.2.9.Catches of sprat 1987–2022 ICES subareas 6 and 7 excluding 7.d and 7.e (Celtic Seas Ecoregion) by Ices Division.

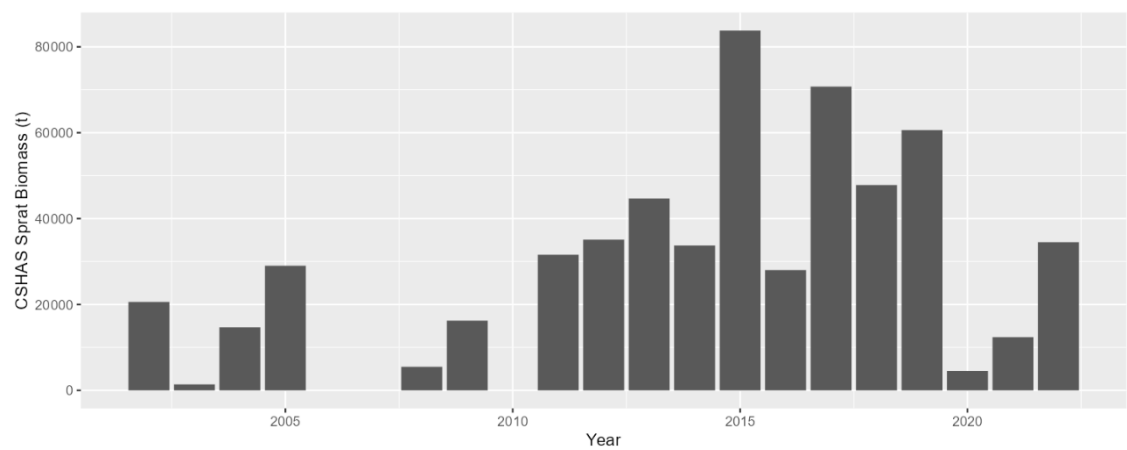

Figure 12.3.1. Sprat in the Celtic Seas Ecoregion. Estimated sprat biomass from the MI Celtic Sea Herring Acoustic Survey 2004–2022 (A4705).

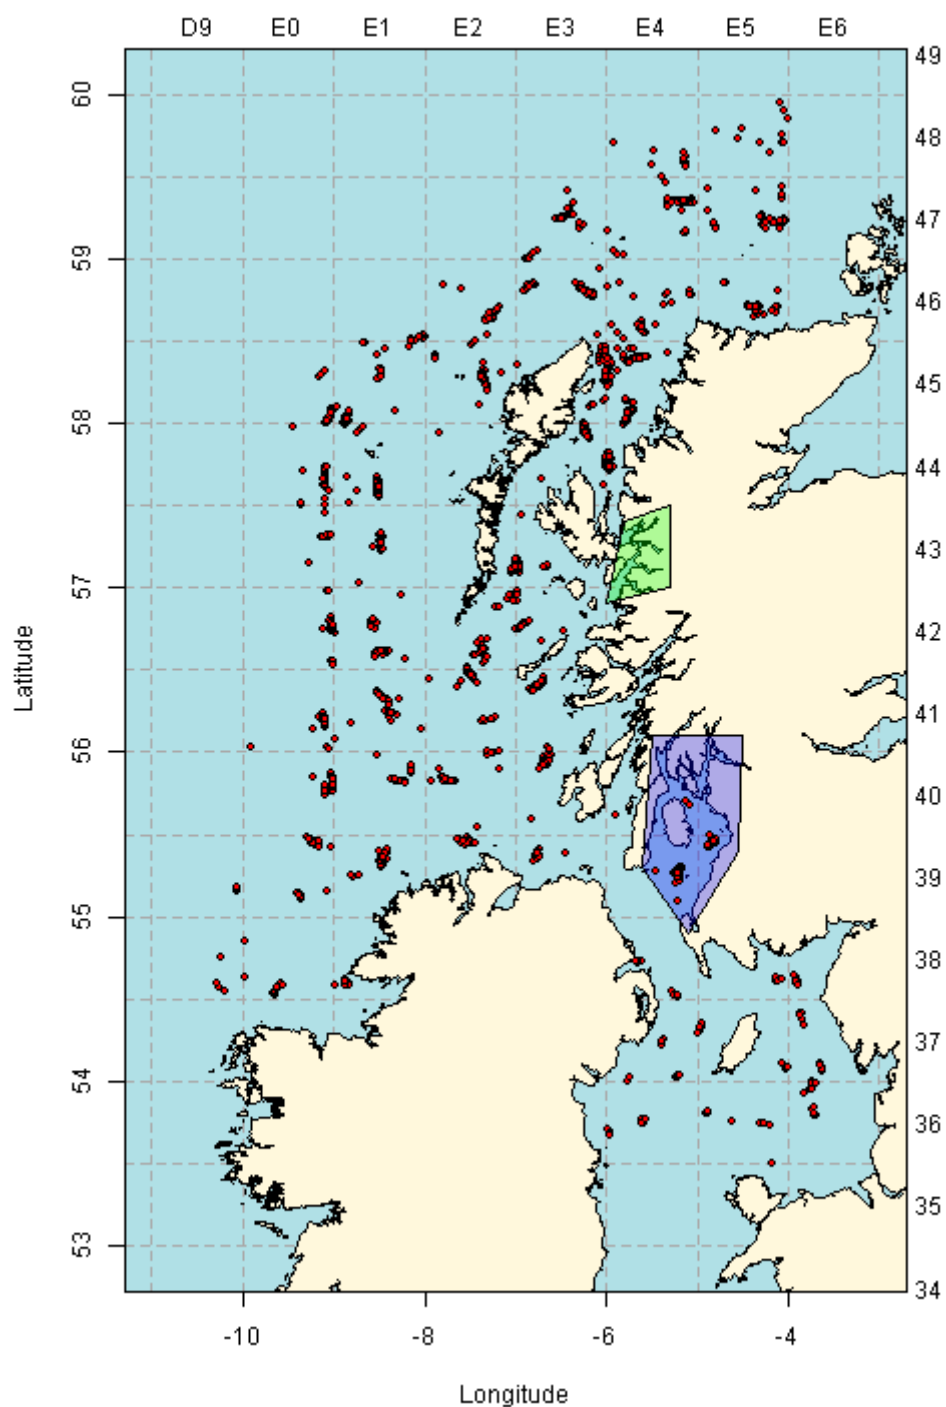

Figure 12.3.2: Extent of Scottish surveys that may provide information about sprat in 6.a. In purple is the extent of the Clyde Herring and Sprat Acoustic Surveys carried out in July between 1985 and 1989 and again in October 2012. In green is the extent of the Sea Lochs Surveys carried out annually in Q1 and Q4 between 2001 and 2005. Red markers indicate all hauls from the Q1 and Q4 Scottish West Coast IBTS between 1985 and 2012 (G7144).

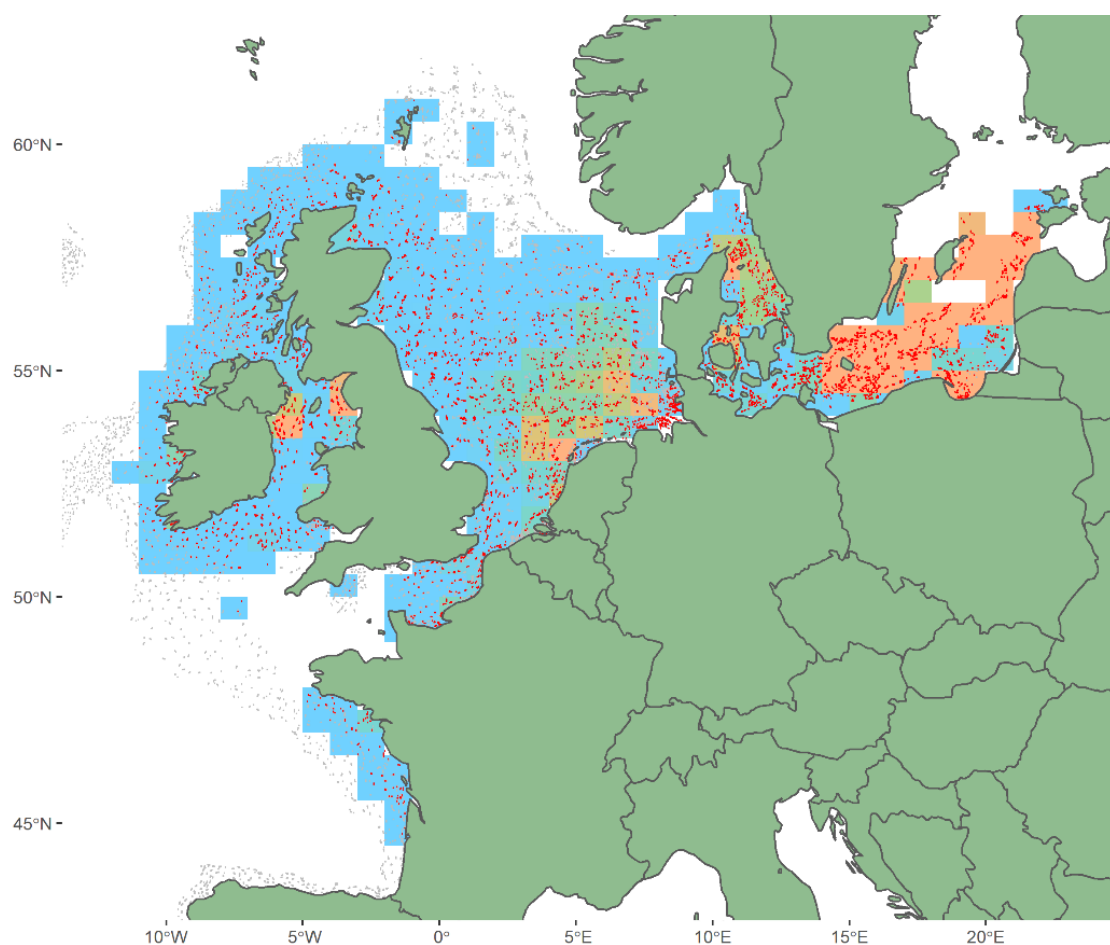

Figure 12.3.3. Total numbers of sprat caught by DATRAS surveys by ICES rectangle, adjusted for tow duration but not adjusted for number of hauls. Since this is a sum, no compensation is made for the varying number of hauls per rectangle. Generated using DATRAS records downloaded 29 Oct 2022, Figure applies to sum over time period 2011-2022. Red dots indicate hauls which caught sprat, grey dots indicate hauls with no sprat recorded. Combined DATRAS survey data for the surveys of acronym: BITS, BTS, BTS-VIII, DYFS, FR-CGFS, IE-IGFS, NIGFS, NS-IBTS, PT-IBTS, SCOROC, SCOWCGFS, SNS, SP-ARSA, SP-NORTH, SP-PORC, EVHOE. See DATRAS website for details on survey acronyms.

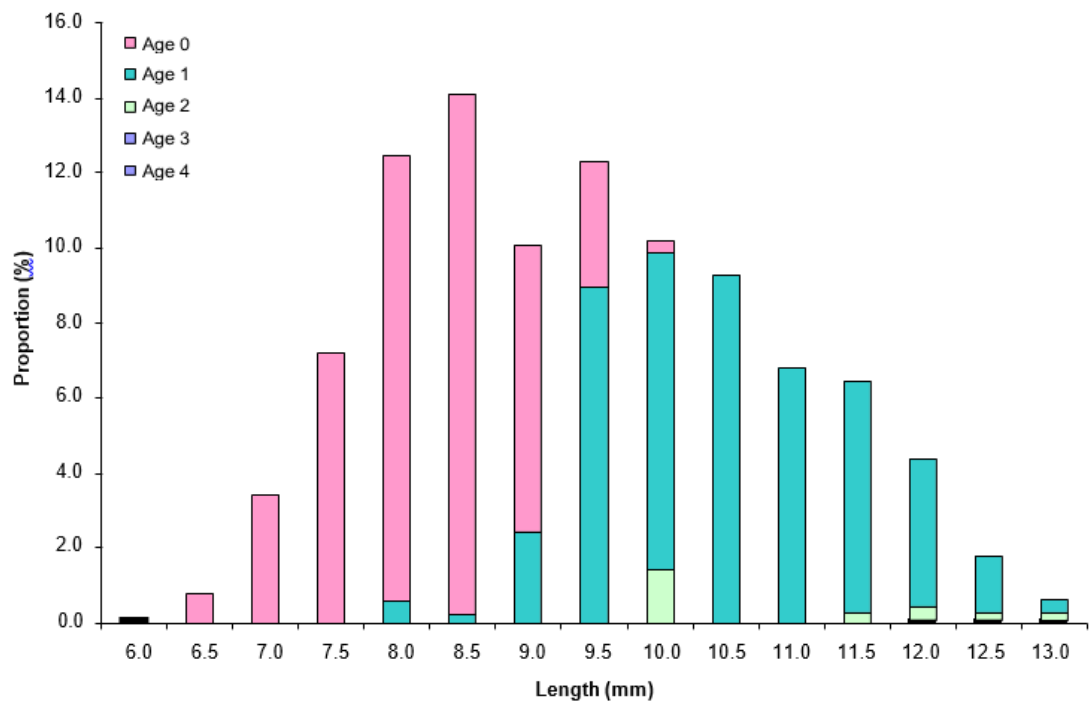

Figure 12.3.4. Length and age of sprat caught in the October 2012 Clyde Herring and Sprat Acoustic Survey. Data from six hauls were combined giving equal weight to the age and length distribution in each haul. 1442 sprat were measured and 182 were aged (G7144).

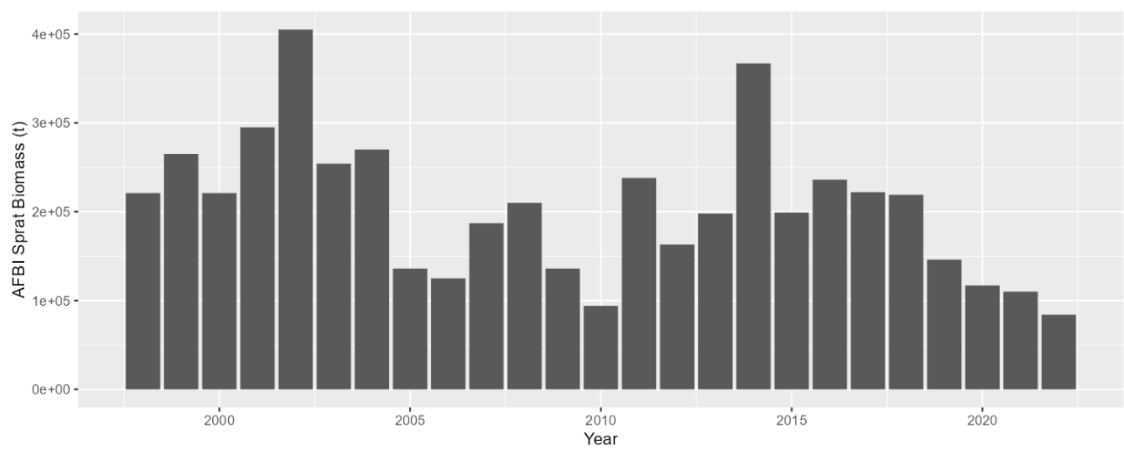

Figure 12.3.5. Sprat in the Celtic Seas Ecoregion. Annual sprat biomass in ICES Division 7.aN from the AFBI Acoustic Survey (A4075)

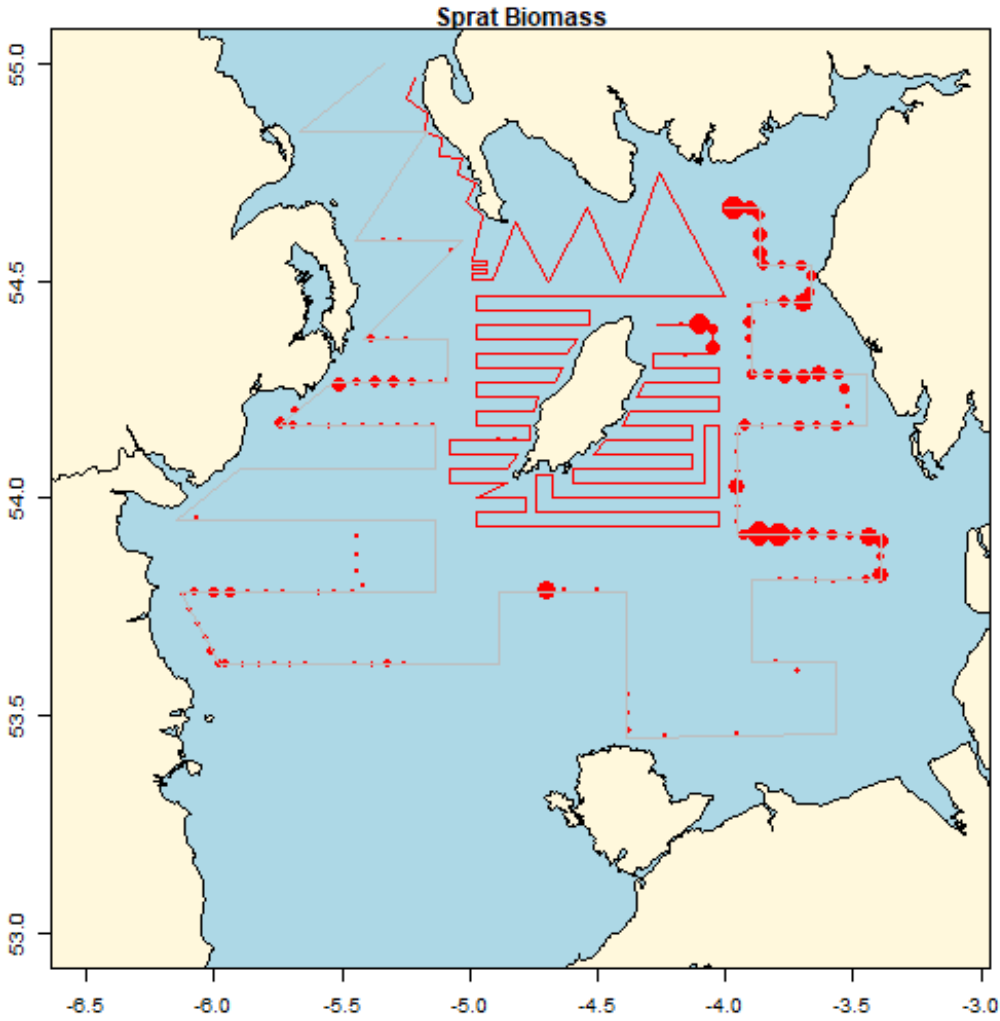

Figure 12.3.6. Map of the Irish Sea and North Channel with a post plot showing the distribution of NASC values (size of ellipses is proportional to square root of the NASC value per 15-minute interval) which include juvenile herring and sprat. Obtained during the 2021 AFBI acoustic survey (A4705).
