Executive summary

The Working Group on the Biology and Life History of Crabs (WGCRAb) met in Aberdeen, Scotland, 1–3 November 2016, with AnnDorte Burmeister as chair. The meeting was attended by 16 participants from 6 countries.

The objectives of the meeting were to update and provide data and knowledge on landings, fisheries and biology of the important crab and lobster stocks in the ICES area. In addition, essential objectives were furthermore to discuss important crab and lobster stocks to identify gaps in assessment programs and review application of biological and management reference points for crab fishery. The WG also reviewed alternative indicators in assessment of crab stocks without fishery independent data.

The first 2 days the work was focused on ToRs a, b, and c. Updates on landings and stock status/assessments on Brown crab and lobster in UK, Scotland, France and Brown crab in Norway; Snow crab in Canada, Greenland and Norway (Barents Sea); Spider crab in France and Red King crab in and Norway were presented.

ToR e “Review research and new knowledge of vital crab population biology parameter” was discussed on days 2–3. Presentation of topic such as: the biology and eco-physiology of *Cancer pagurus* in Norway; population genetic structure in North Eastern Atlantic; movements of brown crab around the North Coast of Scotland; VMS-based effort for the offshore brown fishery in Scotland; discard and survival and condition of brown crab; Dynamic of snow crab movements and migration along the Newfoundland and Labrador and astern Barents sea continental shelves and Size at maturity; and population dynamics of Green crabs (*Carcinus maenas* L.) in Mainland Orkney, Scotland.

The brown crab (*Cancer pagurus*) and the European lobster (*Homarus gammarus*) are both highly valuable shellfish species in the Northeastern Atlantic, but at present, whilst ICES WGCRAb provides a useful forum for brown crab scientists, there is only few lobster equivalent. Both species are typically caught using baited traps and although targeting does occur, they are often regarded as being exploited as a mixed fishery. Availability of fishing activity data and the similarity of their respective biological attributes has led to fisheries scientists using the same or similar stock assessment methodologies for both species. Furthermore, the same fisheries scientists within each fisheries institute are often responsible for both crab and lobster stock status assessments.

The WG decided to continue reviewing prospects for future assessment, advice including data availability, assessment methods and research on the biology of crab and lobster. The group agreed to make progress in evaluating assessment methods, sharing new knowledge of the species and working toward collaborating projects. The WG also agreed also to highlight research results on important crab and lobster species within the ICES, Atlantic Canada and West Greenland.

ToR	DESCRIPTION	BACKGROUND	SCIENCE PLAN		EXPECTED DELIVERABLES
			TOPICS ADDRESSED	DURATION	
a	Compile data on landings, discards, effort and catch rates (CPUE) and provide standardised CPUE, size frequency and research survey data for the important crab and lobster (<i>Homarus</i>) fisheries in the ICES area, and Atlantic Canada and Greenland.	The fisheries for crabs and lobster are socio-economically important and trans-national in Europe and Canada with the demise of fin fisheries in some regions.	212,321	3 years	Landing, discard, effort and catch data on listed species, from each country. WG report chapter
b	Evaluate assessment of the status of crab and lobster (<i>Homarus</i>) stocks including use of indicators, empirical assessment, analytical assessment in relation to data sources and data quality, development and suitability of reference points for management.	Management of stocks in Europe is primarily by technical measures only and in most countries there are generally no management instruments to control fishing effort. Knowledge of the population dynamics of these species is still weak. These stocks may be at risk from over-fishing due to the lack of control of fishing effort, and hence an evaluation of the sustainability of these fisheries is necessary.	311, 334	3 years	Report on evaluation of alternative assessment methods.

c	<p>WGCRAb wish to produce assessment of the main crab and lobster species in the ICES area in future.</p> <p>(Year 1 - 2014) Review prospects for future assessment including data availability, management units, and possible reference points and assessment methods. Initiate preliminary assessment exercises.</p> <p>(Year 2 - 2015) Review management measures applied in crab fisheries and future options. Continue exploratory assessments.</p> <p>(Year 3 – 2016) Preliminary assessments of stock status for relevant crab and lobster species according to MSFD D3</p> <p>WGCRAb will discuss with ACOM, SCICOM, SSCEPD the feasibility of including e assessment within its future ToRs.</p>	<p>WGCRAb aims to produce assessments on a management unit basis.</p> <p>Evaluate current assessment methods and identify reference points. Develop assessment methods to identify position with respect to MSY proxies and harvest rules.</p> <p>It would be of great interest to make progress on assessment of stock status and further develop ideas on reference points.</p> <p>WGCRAb will discuss advantages and disadvantages of emphasis advice on a management basis.</p> <p>Secondly WGCRAb will include a workshop at the 2015 or 2016 meeting to look at prospects for future assessment and management.</p> <p>Third step is to consult with ACOM regarding assessment from the WGCRAb.</p>	112, 113	3 years	<p>(Year 1) Report on data availability, management units, reference points and assessment methods</p> <p>(Year 2) Report on management options for crab fisheries</p> <p>(Year 3) Preliminary report on stock status and management plans for selected species</p>
d	<p>Review the impact of climate divers on important crab and lobster species within the ICES, Atlantic Canada and West Greenland, including increased ocean acidification;</p>	<p>WGCRAb will investigate the relative importance of fishing and environment on crab and lobster recruitment.</p> <p>Furthermore there is a growing concern in the WG about the consequences of future climate change for important crab species in our region. Observed increases in sea water temperatures have already entailed expanded distribution areas of some species in the northeast Atlantic. However, a rise in the seawater pH would probably be the most serious consequences of the climate change on crustaceans such as crabs. These issues will be dealt with by the WGCRAb in future.</p>	112, 113	3 years	<p>Highlight important issues to be basis for research on effect of climate changes on important crab stocks.</p> <p>WG report chapter (2016)</p>
e	<p>Review research and new knowledge on vital crab and lobster population biology parameters;</p>	<p>Several stock parameters are important for analytical assessments. Biological information is therefore required to provide standardised indices and for use in analytical assessments. Crab stock</p>	141		<p>Updated knowledge on crucial stock parameters for important crab stocks.</p>

parameters may change due to size selective and single sex fisheries, through by-catch in other fisheries or through the impact of other seabed uses, such as gravel extraction. Since important crab stocks in Europe are managed without fishery independent data it may be an option to investigate any useful stock parameter indicators for assessment purposes.

3 Summary of Work plan

Year 1	Annual standard outputs for a, b. Continue analysis for ToR d, e. Tentative plan for ToR c.
Year 2	Annual standard outputs for a, b. Continue analysis for ToR d, e. Complete evaluation of useful assessment methods to assess crab and lobster species in ICES areas. Complete request to ACOM and SCICOM (being both an assessment, advice and working group).
Year 3	Annual standard outputs for a, b. Combine analysis, research and report ToR d and e.

4 Summary of Achievements of the WG during 3-year term

4.1 Norwegian *Cancer pagurus* stock

- Annual contributions to the WGCRAb report on stock status of the *Cancer pagurus* stock along the Norwegian coast.
- Stock summary of the Norwegian *Cancer pagurus* stock in an annual IMR-report for the public
(http://www.imr.no/filarkiv/2016/03/havforskningsrapporten_2016.pdf/nb-no).
- Postdoc (2014–2016) working on the genetic stock structure and age determining methods
- Data set on the Norwegian reference fleet of crab fishers (2001–2015) has been given to Snorre Bakke at Møreforskning to analyse as part of his PhD on edible crab
- Report from joint project by Møreforskning and Institute of Marine Research (led by Møreforskning): Woll, A., Søvik, G., Larssen, W.E., Thangstad, T.H. 2014. Ressursmessige og økonomiske konsekvenser av et fiske etter taskekrabbe (*Cancer pagurus*) utenom hovedsesong. Rapport MA 14-09. 64 pp. English translation: Resource and economic consequences of a crab fishery (*Cancer pagurus*) outside the main fishing season.
- Haig, J. A., S. Bakke, M. C. Bell, I. S. M. Bloor, M. Cohen, M. Coleman, S. Dignan, M. J. Kaiser, J. R. Pantin, M. Roach, H. Salomonsen and O. Tully (2016). "Reproductive traits and factors affecting the size at maturity of *Cancer pagurus* across Northern Europe." *ICES Journal of Marine Science: Journal du Conseil*.

4.2 England and Wales brown crab and lobster

- *Advisory products:* Centre for Environment Fisheries and Aquaculture Science (Cefas) provides management advice on the stocks of *Cancer pagurus* and *Homarus gammarus* in English and Welsh waters based upon the assessments performed every two years.
- *Datasets:* Cefas use three datasets to assess brown crab and lobster fisheries in England and Wales: landings, fishing effort and size distribution of landings. The landings and fishing effort data for over 10 meter vessels come from mandatory EU logbooks. For under 10 meter vessels the landings data are collected from first sales notes and the fishing effort from Monthly Shellfish activity returns (MSARs). Scientific officers visit ports frequently to collect size data. Additional size data have also been incorporated from local Inshore Fisheries and Conservation Authorities (IFCAs) since 2013.
- *Modelling output:* Length based Cohort Analyses are performed every two years to estimate abundance and fishing mortality at length for *Cancer pagurus* and *Homarus gammarus*. Length based VPA, Yield, spawner and egg per recruit models are performed to assess the current status of the stocks relative to reference points.

4.3 Greenland – snow crab

- Annual contributions to the WGCRAb report on stock status of the *snow crab* stock in west Greenland waters.
- Stock summary of the snow crab stock in an annual GNIR-report: <http://www.natur.gl/biologisk-raadgivning/skaldyr/>
- *Advisory product:* Greenland Institute of Natural Resources provides management advice on the stock *snow crab* from *West Greenland* waters based upon the assessments performed every two years.
- *Datasets:* Greenland Institute of Natural Resources use datasets from commercial logbooks as well as data from research survey in the management area Sisimiut to assess the snow crab fishery in Greenland..
- *Modelling:* No analytical assessment have been conducted, and currently the stock is assessed based on stock indices from logbooks and research survey. Nevertheless, in attempt to improve the quality of assessment, the SPiCT model and other models recommend in ICES report “ICES. 2012. ICES Implementation of Advice for Data-limited Stocks in 2012 in its 2012 Advice. ICES CM 2012/ACOM 68. 42 pp” and “ICES. 2015. Report of the Fifth Workshop on the Development of Quantitative Assessment Methodologies based on Life-history Traits, Exploitation Characteristics and other Relevant Parameters for Data-limited Stocks (WKLIFE V), 5–9 October 2015, Lisbon, Portugal. ICES CM 2015/ACOM:56. 157 pp.” will be investigated.

4.4 Canada

- For snow crab a draft manuscript entitled 'Dynamics of Snow Crab (*Chionoecetes opilio*) Movement and Migration Along the Newfoundland and Labrador and Eastern Barents Sea Continental Shelves' was presented in 2016. The manuscript had been submitted for primary publication prior to meeting. The manuscript was collaboratively developed by Canadian and Russian members of the working group.
- Over the past 3 years data has been presented on snow crab throughout the Atlantic Canadian region, encompassing the full spatial scale of the stock. This was not the case historically, where research was presented on smaller-scale regions within the stock range.

5 Final report on ToRs, workplan and Science Implementation Plan

5.1 Norwegian edible crab (*Cancer pagurus*) stock

5.1.1 ToR a) Landing, discard, effort and catch data

There are regional differences along the Norwegian coast regarding landings, landings and discards rates, size, and sex ratio in landed catch of the edible crab. Data are therefore presented separately for seven statistical areas as defined by the Norwegian Directorate of Fisheries (Figure 1).

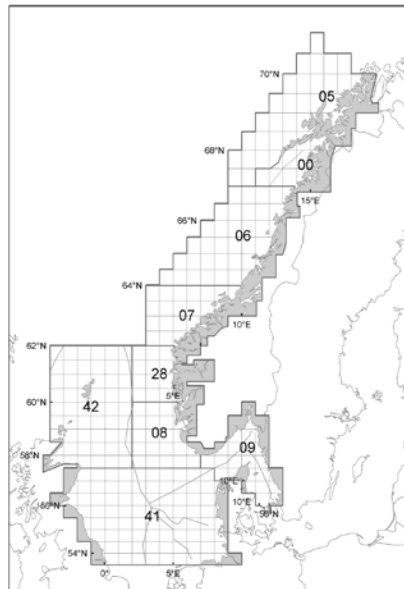

Figure 1. Statistical areas as defined by the Norwegian Directorate of Fisheries.

Landings

The Norwegian landings of edible crab have since 2008 fluctuated without trend (Figure 2). In 2015, 4744 tons were landed. Mid-Norway is the main crab fishing area (statistical

areas 6 and 7). Crabs are probably sold unregistered in all of Norway. From 2010 onwards, all crabs sold to consumers in area 9 must be reported.

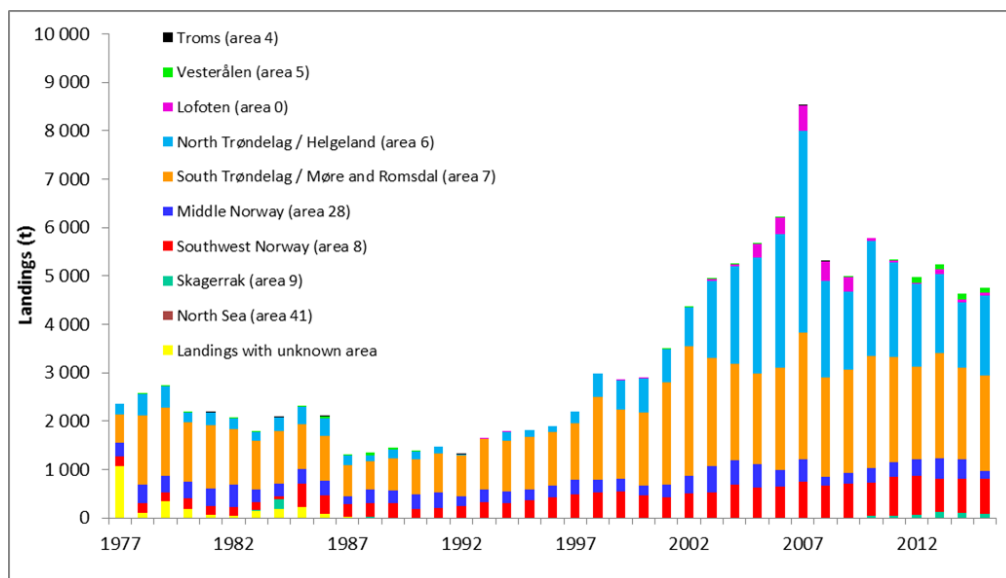

Figure 2. Norwegian landings of *Cancer pagurus* per statistical area, 1977–2015. Data from the Norwegian Directorate of Fisheries.

Stock data

There are no data on fishing effort from the Norwegian crab fleet.

Stock and catch data for the Norwegian edible crab stock come from a reference fleet of crab fishers (Table 1), providing data on landings and discards rates (unstandardised), size (carapace width) and sex ratio. The fishers are equipped with four standard experimental traps with no escape vents (inserted into chains of ordinary traps) from which they provide catch data from weekly fishing trip in 10 consecutive weeks. All crabs in the standard traps are measured and the following recorded:

- Carapace width (CW)
- Sex
- Females with external roe (discards)
- Soft crabs (discards)
- Crabs below minimum legal size (MLS); (discards)
- Other discards (damaged crabs, crabs with black spots or missing limbs)

Landings and discards rates are calculated as kg crab per standard trap per day. Data from all years were recalculated in 2014 as rates in previous years were not corrected for soaking time of the traps. Crab weight is estimated using known size-weight relationships, calculated for respectively mature females, mature males, and juveniles (< 13 cm CW); (Woll *et al.* 2006).

Table 1. Number of fishers in the reference fleet per statistical area, and total number of crabs caught in the standard experimental traps (2001–2015).

Year	Statistical area							Total # crabs
	8	28	7	6	0	5	Total	
2001			10	8		1	19	20 614
2002	4		9	9		3	25	29 831
2003	4		9	9		3	25	27 028
2004	3		6	9		1	19	7875
2005			3	7		1	11	7515
2006			4	8	2	1	15	5169
2007	4		4	6		1	15	7135
2008	1		2	4		1	8	3778
2009	3		1	1			5	2966
2010	2	2	3	3			10	4769
2011		2	2	3			7	2877
2012	2		4	6		2	14	9098
2013	2	1	4	7		2	16	9152
2014	2	1	3	3		2	11	4444
2015	2		4	5		1	12	4742

Due to few fishers in the reference fleet in 2008, 2009, and 2011, catch rates from these years are uncertain. For some statistical areas the index is based on data from only one fisher. The data situation improved in 2012 and 2013 due to an externally financed project on economical and stock effects of crab fishery outside the main season (August–October).

In area 5, landings rate (LPUE) was high compared to the discards rate (DPUE) in previous years (Figure 3). But LPUE of 3–5 kg/trap day decreased from 2012 to 2015. In area 6, LPUE has been 2–4 kg/trap day since 2001, except in 2009. The drop in LPUE in 2009 was due to sales organization introducing a MLS of 14 cm this year. Further south, in area 7, LPUE has been 2–3 kg/trap day in the first and last part of the time series, while it was around 4 kg/trap day in 2007–2011. This high LPUE might have been due to few fishers participating these years, such that the rate was influenced by the skills of these fishers. Annual LPUE-values varies a lot in area 8. In 2014, it was 5.1 kg/trap day, but decreased to 3.0 kg/trap day in the following year.

Areas 8 and 28 have the highest DPUEs (Figure 3). Area 28 is an area with little fishery and the high discards could be due to crabs of low quality not having been fished out of the stock. In area 8 (southernmost area) more than half the catch has been discarded in some years (soft crabs, specimens below MLS, crabs with black spots and missing limbs) (Figure 4). Crabs below MLS make up most of the discards from the middle and northern part of the coast, while further south, soft and damaged crabs are dominating the discards. A larger proportion of soft crabs in the catches in the southern areas compared with North-Norway indicates that a larger proportion of the stock moults each year in

South-Norway. The number of berried females is very low in the catches from the reference fleet. Berried females are inactive and thus not available to the traps.

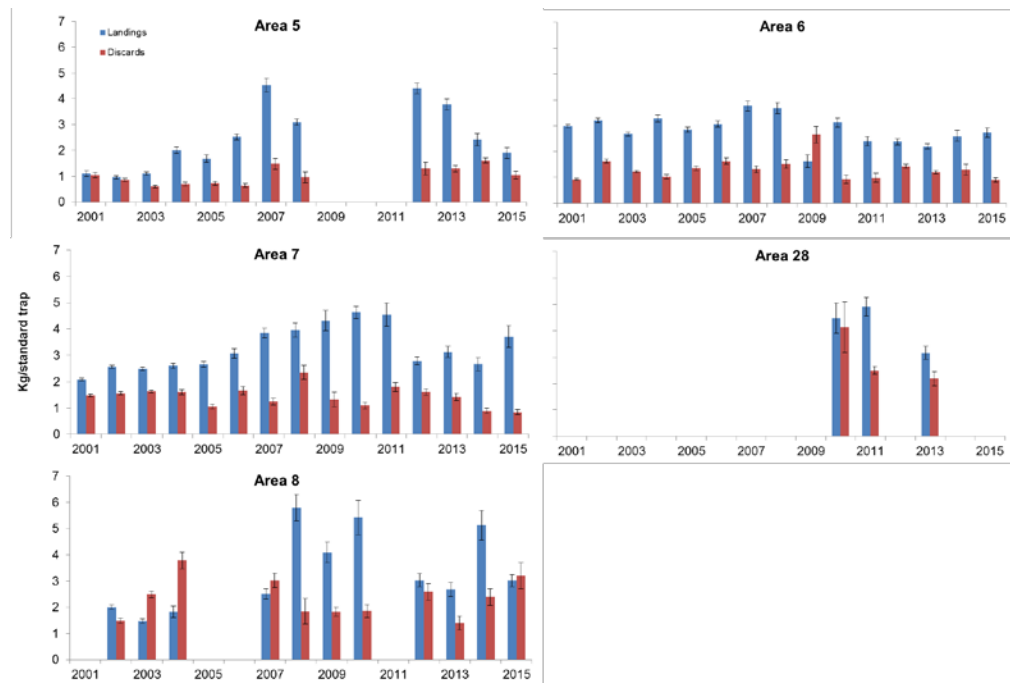

Figure 3. Indices of landings rate (LPUE) and discards rate (DPUE) from the standard experimental traps (mean \pm standard error) from the reference fleet of crab fishers, per statistical area for 2001–2015.

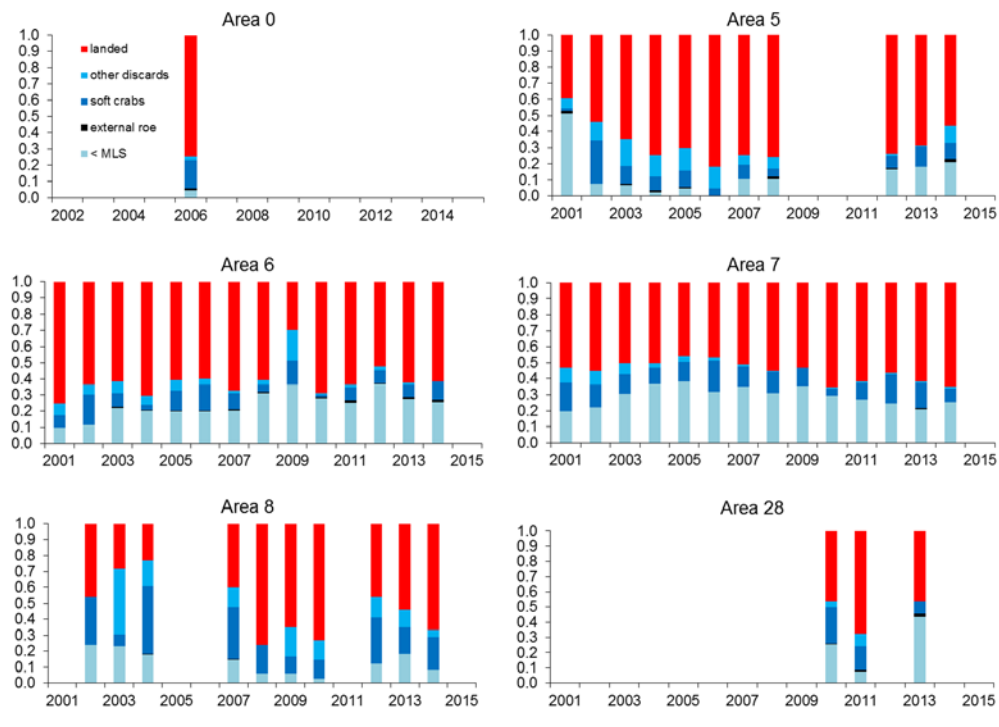

Figure 4. Proportions of landed and discarded catch from the reference fleet of crab fishers, by statistical area for 2001–2015.

In the first part of the time series there was a clear geographical trend in the proportion of females in the landings from the standard traps, with an increasing proportion with latitude (Figure 5). Since 2010, the proportion of females has been more similar in the areas 6, 7, 28, and 5. In area 8 in the south, the proportion of females in the landings has varied between 40 and 60% throughout the whole time series. The proportion of females in the catches increases throughout the fishing season, and then declines again in October–December. This is due to the females migrating into shallower areas to feed and spawn. After spawning, as berried females, they become less active and thus less available to the traps.

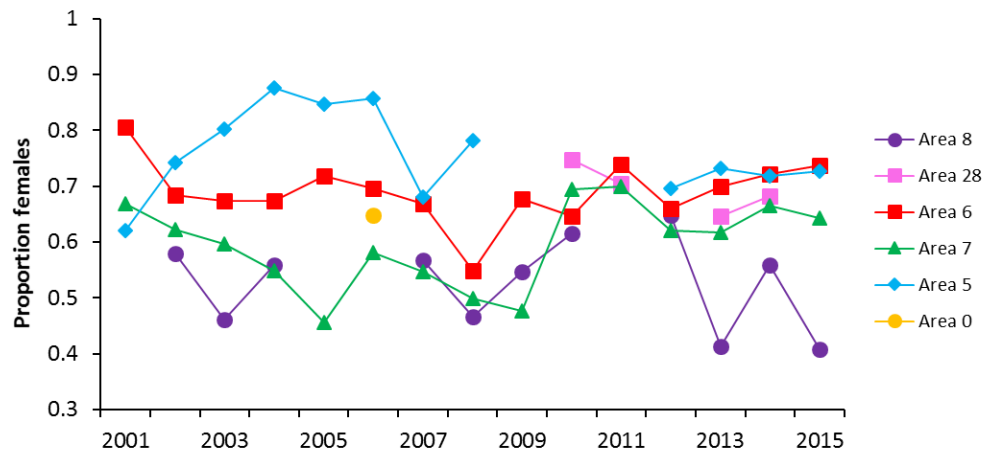

Figure 5. Proportion of females in landed catch per statistical area and year.

Mean size in landed catch is lowest in area 8 due to the lower MLS in this area. Mean CW for both males and females is between 13 and 14 cm (Figure 6). The largest crabs are found in areas 7, 5 and 28, where mean size lies between 15 and 16 cm CW. Males are generally larger than females. The large crabs in area 28 can be explained by the low fishing pressure. Area 6 stands out by a lower mean CW for both males and females, and the mean size has decreased from the start to the end of the time series (from around 15 cm to around 14 cm).

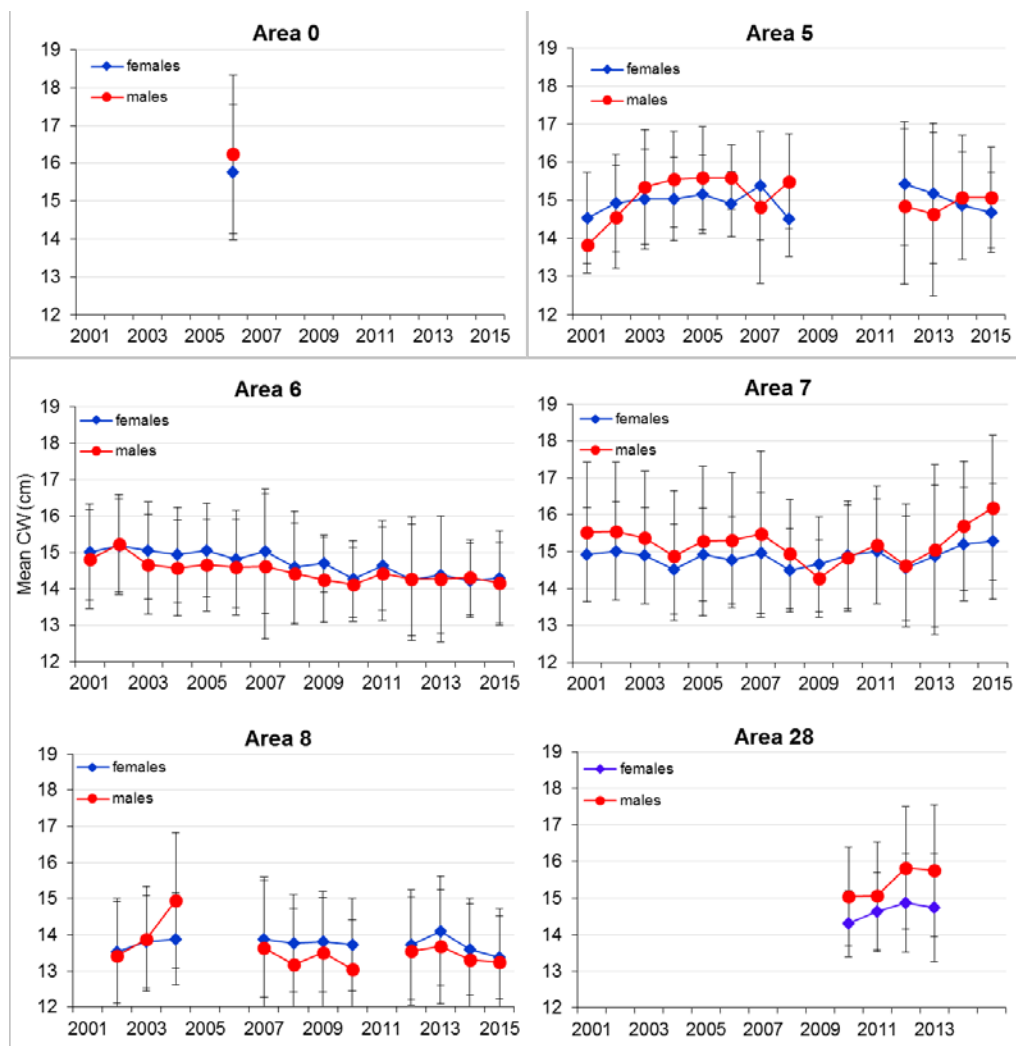

Figure 6. Mean CW (\pm stdev) of males and females in landed catch from the reference fleet of crab fishers, by statistical area for 2001–2015.

5.1.2 ToR b) Evaluation of alternative assessment methods

Alternative assessment methods have not been evaluated for the edible crab stock along the Norwegian coast.

The state of the stock is assessed by evaluating indicators from a reference fleet of crab fishers (LPUE and mean size in landings). The reference fleet has for several years and for some areas (notably 8, 28 and 5) too few participating fishers. Woll *et al.* (2006) concluded, after 4 years of collecting data from the reference fleet, that “The most efficient survey design is seemingly the collection of relatively small samples from many boats to reduce the between-vessel component of variation”. In 2016, it was decided to go from an annual to a bi-annual collection of data from the reference fleet, and thereby use limited resources on a larger sampling effort every second year. There was therefore no data collection in 2016. In 2017, the goal is to collect data from 2-3 fishers in areas 8 and 5, and from 7–9 fishers in areas 6 and 7.

The assessment of the fishery on the Norwegian crab stock is suffering from a lack of effort data for the whole fleet. Electronic log books are only compulsory for vessels ≥ 15 m, and as the crab fleet is dominated by small vessels, this data source is not available. It should, however, be possible to register the number of traps upon landing of catches. Woll *et al.* (2006) noted that “A suggested strategy to obtain an abundance index would be to collect daily catch rates from all commercial landings”.

5.1.3 ToR c) Preliminary assessment of stock status

It is difficult to say something certain about the total stock development of the Norwegian edible crab. Stock indicators (LPUE, mean size in landings) indicate a stable stock in most of the statistical areas. However, in area 6, mean size of both males and females have decreased from the beginning of the time series to recent years. Length frequency distributions reveal that the size of the crabs in area 6 dropped from 2007 to 2008, after record high landings in 2007, and have since remained smaller compared with earlier years. Similar changes are not seen in area 7, where landings are of equal size as in area 6. This indicates that the fishing pressure is higher in area 6 than in 7.

The development of the crab fishery has been different in areas 6 and 7. The landings from area 7 have since 2001 remained at a stable level, while the landings from area 6 increased substantially from the late 1990s to 2007 (Figure 3). The large increase may have been possible due to the stock earlier being at or just below the area's carrying capacity.

5.1.4 ToR d) Impact of climate drivers including acidification

The Norwegian crab stock is moving north along the Norwegian coast, likely due to warming of the sea. There has been no Norwegian research on the effects of acidification on the edible crab.

5.1.5 ToR e) Research and new knowledge on population biology parameters

A Spanish postdoc is working on the genetic stock structure of the edible crab in the North Atlantic from Galicia to northern Norway. The work needs to be written together and published.

The same postdoc is currently working on direct age determination of the crab, by counting zones in cuts from gastric mills.

A PhD focuses on the biological and eco-physiological differences in crabs along the coast of Norway. Results from analysis of size at maturity (size where 50 % of the crabs are mature) indicate no difference between northern and southern Norway. There is ongoing work to read growth bands in the gastric mill structures of individuals from north and south of Norway to determine if there are differences in age at same size (and maturity). Modelling of probability of molting using Generalized Additive Models have been conducted using data on presence of soft crabs in catches collected by the reference fleet of crab fishers. The analysis show that the probability of moulting is lower in the northern population of *C. pagurus* compared to southern Norway, indicating a slower growth with increasing latitude. Results from modelling further show a delayed peak period for molting in northern Norway compared with locations further south.

In the eco-physiological part of the PhD the focus is on the geographical differences in thermal preference and the effect of temperature on *Cancer pagurus* metabolism. The thermal preference of (individual) crabs from northern Norway (Senja, Troms) and from central Norway (Ålesund, Møre og Romsdal) have been investigated by monitoring their movement in a raceway system with a thermal gradient (~6–16 °C). The results show no obvious differences between crabs from Senja or Ålesund in terms of thermal preference, with crabs (irrespective of origin) spending most of its time in the range 12–14 °C. Clear differences in night/day activity were found where crabs moved throughout the whole thermal gradient during night time but returned to the warmer areas of the tank with onset of light. During daytime the crabs remained stationary (in the warmer areas of the tank) with very little or no movement. Analysis of the movement of crabs within the thermal gradient showed that crabs moved a maximum of 1.3–1.6 °C/minute. No clear differences were found in the ability of crabs to move between temperatures when comparing crabs from Senja or Ålesund.

5.2 Scottish edible crab (*Cancer pagurus*) stock

5.2.1 ToRs a) and b) Stock status of brown crab in Scotland

Total Scottish landings of brown crab fluctuated between 9300 and 12 300 tonnes from 2008 to 2015 (Table 2). The principal fishing areas for brown crab in Scotland are Orkney, Hebrides, Sule, East Coast, North Coast, Papa and South Minch; landings from these areas accounted for around 88% of the total in 2015. Landings from the offshore areas of Sule and Papa have increased sharply in the 1990s when the fishery expanded, but seem to have stabilized in Papa and decreased in Sule in the last three years. Landings from Orkney, East Coast and Hebrides show an increasing trend in recent years. The spatial distribution of brown crab landings by ICES statistical rectangle (including Irish landings) is shown in Figure 7. The majority of crabs fished in Scottish waters are landed in the third and fourth quarters of the year. Stock assessments based on LCAs for the period 2013–2015 were carried out for nine of the twelve assessment units, providing estimates of fishing mortality in relation to the F_{MSY} proxies. No assessments were performed for Mallaig and Ullapool as the sampling data collected were considered insufficient to run LCAs. The results of the 2013-15 assessment are still at a preliminary stage. Of the nine assessed areas, eight were fished above the F_{MSY} proxy to some extent (Table 3). Fishing mortality was estimated to be above F_{MSY} for both males and females in Clyde, East Coast, North Coast, Orkney, South East, South Minch and Sule. In the Hebrides, fishing mortality for males was at F_{MSY} while females were fished above F_{MSY} . In Papa, recent fishing mortality was around F_{MSY} or lower. Overall, preliminary assessment results for the period 2013–2015 showed that brown crab in most of the assessment units in Scotland were fished close to or above the F_{MSY} proxy. In many of the assessment units, a higher yield and biomass per recruit in the long term could potentially be obtained by reducing the level of fishing mortality (effort).

5.2.2 ToR b) Length-based indicators for crustaceans stocks

In the absence of scientific surveys and ageing methods to support a stock assessment, reliable length frequency data of sampled catches can be used to support an indirect assessment of stock status of data-limited crustacean stocks. Length-based indicators are a simple tool to describe the length frequency distributions of catches. Indicators can help to evaluate the presence of very large individuals in the catches and exploitation level with regard to maximum sustainable yield (MSY) and the protection of immature individuals. We used a length-based sex-structured population model to simulation-test the selected length-based indicators, the mean length and the mean length of the largest 5% in the catch, and their reference points in harvest control rules for the management of a data-limited stock. Length-based indicators can be used in harvest control rules to recover overexploited stocks. The mean length is more sensitive to the length at first catch or minimum landing size. To restore overexploited stocks a precautionary reference point is advised to quickly reach MSY and keep the risk of collapse low.

Currently, as management measures there are minimum landing sizes implemented for crab and lobster stocks. No TAC, quota or harvest control rule in use. We illustrate the use of length-based indicators for Scottish crab and lobster stocks and attempt the description of exploitation status relative to MSY which can be compared to LCA outputs. Indicators are calculated for each sex separately, as crustaceans are sexually dimorphic. A range of length-based indicators are available to assess fisheries selectivity, monitor changes and infer stock status (Blanchard *et al.*, 2005; Shin *et al.*, 2005; ICES WKLife, 2015; Mithé *et al.*, 2016). Indicators and their reference points are listed in Table 4. Reference points for length-based indicators are based on life history characteristics such as the asymptotic length L_{∞} from the von Bertalanffy growth equation (ICES WKLife, 2012). The reference point L_{mat} (length at which 50% are mature) can be used to test whether enough individuals reach maturity before being recruited to the fishery (Caddy and Mahon, 1995). $L_{F=M}$ is recognized as a proxy for the mean length at MSY (ICES WKLife, 2012). To sustain a healthy stock, the abundance of very large individuals can be monitored. The maximum length L_{max} varies over time due to the rarity of very large individuals in the catch. Therefore, $L_{max5\%}$ is a more suitable indicator for the presence of the largest length groups in the catch. The indicator $L_{max5\%}$ was introduced by Probst *et al.* (2013).

Length-based indicators are calculated for brown crabs and lobsters in Scottish waters for females and males, separately. Reference points are calculated according to life history parameters used in Mesquita *et al.* (2016). The ratio of indicators with their MSY reference points are evaluated for mean length \bar{L} and $L_{max5\%}$ as an average for the years 2013–2015 (Table 5, 6). According to the selected indicators for brown crab (Table 7), females and males in Papa as well as males in the Hebrides appear to be sustainably harvested. For lobsters only females in Papa appear to be sustainably harvested with both indicators above their reference points. Brown crabs and lobsters are exploited with minimum landings sizes above L_{mat} . For a number of lobster stocks, the length class with maximum yield was below the expected optimum. Indicators for selected stocks are plotted for the years 2010–2015 (Figure 8.9).

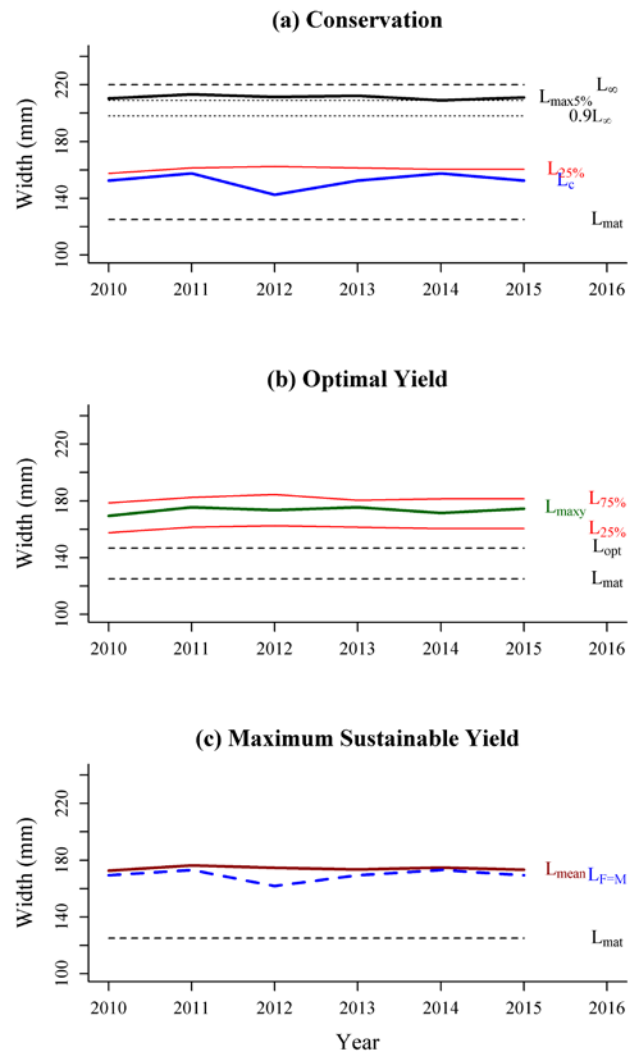

Figure 9. Brown crab, Males, in Papa (PA).

5.2.3 ToRs a) and b) Stock status of lobster in Scotland

Total Scottish landings of lobster fluctuated between 700 and 1200 tonnes from 2006 to 2015 (Table 9). The total tonnage of lobster landed in Scotland has consistently been much lower than that of crabs. However, reported lobster landings have increased substantially over the last years. Historically the majority of landings of lobster in Scotland have been from the Hebrides, Orkney and South Minch, with the South East and East Coast areas becoming increasingly important in more recent years. Landings from these areas accounted for around 85% of the total. Figure 8 shows the spatial distribution of lobster landings around Scotland in the period 2013–2015. ICES rectangle 41E7 in the South East consistently has the largest amount of landings. Small quantities of lobster were landed from grounds outside the assessment areas, including ICES rectangles to the west of South Minch, to the south of Clyde and just outside the South East and East Coast areas. The majority of lobsters fished in Scottish waters are landed in the third and fourth quarters of the year. Stock assessments based on LCAs for the period 2013–2015 were

carried out for eight of the twelve assessment units, providing estimates of fishing mortality in relation to the F_{MSY} proxies (Table 7). Sampling data were considered to be insufficient (low numbers and infrequent sampling) for running assessments in Mallaig, North Coast, Sule and Ullapool. The results of the 2013–2015 assessment are still at a preliminary stage. Lobsters in all the assessed areas were fished above the F_{MSY} proxy to some extent, particularly males. Fishing mortality was estimated to be above F_{MSY} for both males and females in Clyde, East Coast, South East, Shetland and South Minch. In the Hebrides, Orkney and Papa, fishing mortality for females was at F_{MSY} or below while males were fished above F_{MSY} . Overall, preliminary assessment results for the period 2013–2015 show that lobster in most of the assessment units in Scotland were fished close to or above the F_{MSY} proxy. A higher yield and biomass per recruit in the long term could potentially be obtained in all assessment units by reducing the level of fishing mortality (effort).

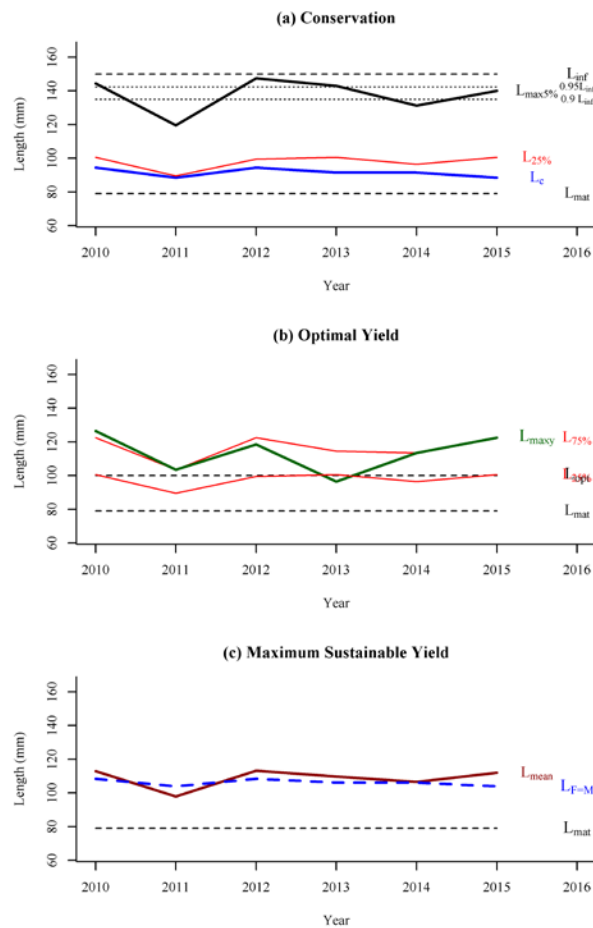

Figure 9.1. European lobster, Females, South Minch (SM).

5.2.4 ToR e) Maturity of brown crab in Scottish waters

In this study, the size at maturity of brown crab was estimated using a variety of reproductive and morphometric criteria from samples obtained in the east and west coast of Scotland; this was estimated as the carapace width (CW) at which 50% of the sample was mature (CW50). Testes and ovaries were staged to estimate the size of gonadal maturity. When stage 2 males were defined as mature, a significant difference between east (100.5mm) and west (107mm) coast samples was identified; no significant difference was found between areas when stage 2 males were defined as immature (170 mm east and 171 mm west). There was also no significant difference between the size of gonadal maturity between east (145.5mm) and west (145.6mm) coast females. Sperm plugs were considered in addition as an indicator of behavioural maturity. Although none were found in east coast females, 84% of west coast females contained them internally; this could be indicative of differences in reproductive cycles. Size of morphometric maturity was estimated using cheliped measurements of males and abdomen/pleopod measurements of females. Although a significant breakpoint was identified for cheliped depth of east coast males, no other breakpoints were found to be significant. The change from isometric to allometric growth of these features was instead best represented by a gradual change.

5.3 Norwegian stock of European lobster (*Homarus gammarus*)

5.3.1 ToR a) Landing, discard, effort and catch data

Landings

The European lobster has traditionally been regarded as a valuable marine resource, supporting the coastal fishery for several centuries. The fishery for lobster goes back to the 1600s (Boeck 1869, Appelöf 1909), and the available statistics describe a national fishery that annually harvested around 900 000 lobsters during the period from 1820 to 1920, corresponding to around 450 tonnes. In the early 1930s, the landings rose sharply to a peak of 1300 tonnes (2.8 million individuals). The increase was probably a combination of good recruitment (Dannevig 1936) and greater fishing effort (Tveite 1991). For a few more decades, annual landings ranged around 700–800 tonnes. Norway was at these times one of the principal countries supplying lobster to the European market, accounting for 24% of total landings in Europe. From 1960 and on, landings declined drastically to 200 tonnes in 1970, and continued to fall to the current level of 30 to 50 tonnes a year. Decades of low landings forced many lobster dealers to close down, and since the 1990s the official recordings probably reflect the capacity of the few remaining dealers rather than actual landings. In addition, since the 1980s, the recreational fishery has increased considerably and has undoubtedly increased the fishing pressure on lobster, although numbers are not recorded (Kleiven 2010).

5.3.2 ToR c) Preliminary assessments of stock status

Regulations

At the time the fishery started, back in the 1600s, the fishery was unregulated much due to the landowner's property rights extending into the sea (Boeck 1869). A strong dispute at the beginning of the 1700s ended in a trial in 1725 with the verdict that lobster (and other marine fish/shellfish) was to be considered a common property right, i.e. for everyone to capture (Boeck op cit.). In 1737, Anderssen Lem suggested, on the basis of decreasing landings, minimum legal size (MLS) of 9–10 inches total length (TL) and a closed

season during the time when lobster were believed to hatch their eggs. This was regarded a weird suggestion at that time and was rejected and forgotten. The landings decreased in the 1830s and added new heat to the discussion about closed season. Another management plan was also suggested, implying that the coastline should be divided into several districts with alternating licenses to fish and land lobster for three years followed by closure for three years, and so on. In the face of strong objections, a closed season was introduced in 1849 (Boeck op cit.), 112 years after it had been first suggested. MLS of 21 cm TL was approved 17 June 1879. An extension of the closed season, increase in MLS and a ban on landing berried females were discussed, proposed and rejected on several occasions. Of greatest concern was that MLS was below the size where female lobster carry eggs. On the basis of this, Appelöf (1909) suggested a MLS of 25 cm TL for the western coast of Norway and 24 cm TL for the Skagerrak coast. In 1964, MLS increased to 22 cm TL. In 1992, MLS increased to 24 cm TL, and the following year to 25 cm from Rogaland county and northwards. Lobsters are legally only allowed to be landed if captured in traps, either baited or unbaited. Trap design and bait vary from location to location, and a major upgrading has taken place the last five years.

It should be noted that the official measure of the size of a lobster in Norway is TL (distance from the anterior tip of the rostrum to the end of the telson), implemented in 1879. On the other hand, in Europe as well as elsewhere in the world, carapace length (CL; distance from the posterior rim of the eye socket to the posterior edge of the carapace) is the official measure in all lobster species, including spiny and rock lobsters (Factor 1995, Phillips 2006; and references therein).

New Management Plan implemented 2008

A working group consisting of members from the Directorate of Fisheries in Norway and the Institute of Marine Research was appointed in 2005 to look at the fishery regulations to protect lobster populations. Moratorium, marine protected areas, releases of hatchery-produced lobster juveniles were debated, along with restrictions as minimum legal size, maximum legal size, prohibitions to land berried females, gear restrictions, escape vents in pots, CL as a measure of size, local management and a "lobster fee". The final working group's report and recommendations were submitted October 2007 (Veim *et al.* 2007) and some of the suggested regulations were implemented in the fishery in 2008. This includes ban on landing berried females, escape vent (60 mm in the lobster fishing season and 80 mm outside the season), MLS of 25 cm TL and seasonal closure. In addition, number of pots per recreation fisher was set to 10 and correspondingly 80 for commercial fisher. A management goal of 0.1 lobster per pot was also set. An evaluation of these regulations should be done in 2017.

Stock enhancement, sea ranching and marine protected areas were also presented.

5.4 England and Wales stock of the edible crab (*Cancer pagurus*) and European lobster (*Homarus gammarus*)

5.4.1 ToRs a) and b) England and Wales: An overview of the edible crab (*Cancer pagurus*) and European lobster (*Homarus gammarus*) fishery status

Brown crab and lobster are very valuable species exploited around the coasts of England and Wales, with landings in 2015 above 14 000t for crab, and 1885t for lobster. With the

aim of informing fisheries managers, Cefas currently produces biennial stock status reports. Each report contains information describing the status of stocks in six crab assessment areas and seven lobster assessment areas in English and Welsh waters. These assessments are run every two years although they have not been updated since the WGCRAb 2013 report.

Both fisheries are mainly targeted by vessels under 12 m that use pots and operate close to the coast, although larger vessels fishing offshore are also present. The most productive areas for crab are Western English Channel and Southern North Sea, which sum 65% of the total landings in 2015. Regarding the lobster fishery, the most productive area is Yorkshire and Humber, whose landings represented the 44% of the total in 2015. Landings in this area have increased progressively since 2006, whereas the fishing effort has been stable since 2011.

The last assessments suggest that some crab and lobster stocks are being fished at a rate either around or above the Fmsy target, and with spawning stock biomass estimates at or below the recommended level. However, problems associated with data consistency, parameter selection and model assumption violations mean that there is uncertainty associated with the assessments. In this sense, bootstrapping will be included in the future assessments to quantify uncertainty relating to the data used to estimate the size structure of the population. Additionally, Cefas has investigated the sensitivity of the assessments to growth and maturity parameters, the results of which will be available at the 2017 working group.

5.5 Orkney stock of the crabs and European lobster (*Homarus gammarus*)

5.5.1 ToR e) Size at maturity and population dynamics of Green crabs (*Carcinus maenas* L.) in Mainland Orkney, Scotland

In this study the size of maturity of green crab was estimated to ascertain the effect of the new management measure imposed onto the Orkney inshore creel fishery in March 2016. This study used two methodologies to estimate maturity, reproductive estimated based on gonad maturation and physiological maturity based on secondary morphological changes. Both methodologies would be used to estimate at what carapace width (CW) 50% of the population was mature (CW50). Gonad staging was done in line with a previous study conducted within the Republic of Ireland, defining individuals as physiological mature or immature based on testes and ovaries size and colour. Based on this methodology 50% of the Female green crabs on the Orkney mainland were defined as mature at 39.4 mm CW, whilst males were defined mature as 42.9 mm CW, a overall combined CW50 was 40.11 mm. Morphological maturity was defined within males as changes in claw development, with such changes linked to behavioural ability to compete for mates. No significant breakpoint in male claw development was identified within green crabs indicating an isometric growth pattern. Similarly the relation between females fourth abdominal segment was investigated, no significant breakpoint in female growth was identified indicating isometric growth.

5.5.2 ToR e) The Movements of Brown Crab (*Cancer pagurus* L.) around the North Coast of Scotland

Brown crabs have been tagged as a part of an ongoing fisheries research project since 2011 on-board inshore commercial creel vessels. The aims of the project were to map the migration pattern of the inshore stock and its possible overlap with the emerging and highly productive offshore brown crab fishery.

A total of 7733 soft shell crabs have been tagged over the course of numerous sampling activities. These tagging projects have provided valuable insight into the migration behaviour of brown crab around the Northern coast of Scotland. The general trend that was observed within the fishery was a westward movement of soft shell female. Individualists were recorded migrating from the south west of the Orkney Island, moving south-west along the Scottish coast, with distances travelled ranging from 50–170km over the course of a year. The longest migration recorded by these tagging exercises were by two female crabs tagged in the September and November 2015, moving distances of 236 km and 258 km respectively, subsequently recaptured in Skye and North West outer Hebrides. These migrations demonstrate the movement of crab stock around northern Scotland, through numerous different management areas and subsequent differing levels of exploitation under current stock assessment outputs. In comparison male brown crab demonstrated limited movement from initial release sites typically <15 km, falling in line with observations documented within Sweden and Norway.

5.5.3 Discard survival and condition in Orkney brown crabs

In this study, the discard survival and condition in Orkney brown crabs will be estimated using a vitality index that supports reflex action mortality predictors (RAMP), from samples obtained on the west side of Orkney mainland; the information collected during this experiment will be used for to determine if damage, sex, shell condition and size (CW) are statistical significant predictors in the RAMP model and what effect differing discarding behaviour has on the survivability of discarded individuals.

The study will be undertaken between end of July 2016 and December 2017. The study will involve the storage of individuals within both tank and at sea storage. A total of thirty sub-legal individuals (bellow 140 mm) will be collected on board a commercial fishing vessel; 10 undamaged individuals (control individuals) and 20 damage individuals (treatment individuals); treatment categories may include varying degrees of damage or moult condition. Sub-dividing the treatment categories, e.g. based on numbers of missing limbs, would be impracticable given experimental resources. Instead, by recording individual condition and by following the fates of individuals in the experiments, the effects of degrees of damage or moult condition will be explored through statistical analysis. The designation of 'treatments' in the experiment is primarily to ensure that the primary distinctions are adequately represented; each individual will be sexed, measured (CW) and numbered with non-toxic Chalk Marker D60; each creel/tank will be baited and placed with five individuals of different sizes and sexes according to the CW range defined for this study.

The RAMP method selected has the advantage that it can be easily applied at sea on research or fishing vessels without the need for tag recoveries. This project will apply

RAMP to brown crab discarded under actual fishing conditions with the goal of evaluating estimates of discard mortality rates.

5.6 Isle of Man stock of the crabs and European lobster (*Homarus gammarus*)

5.6.1 ToR e) Static gear fisheries in Manx waters; using cameras to collect data on commercially exploited crustaceans

The introduction of the Marine Strategy Framework Directive (MSFD) and the reform of the Common Fishery Policy (CFP) requires EU member states to commence and/or improve data collection for data poor species. Even with the result of the UK referendum, there will still be a requirement to meet these reporting obligations and standards. While quota species are generally characterised by regular monitoring programs, which combine fishery dependent and independent data, most of the commercially important non-quota species are usually data deficient. This data deficiency is particularly acute in shellfisheries such as those for brown crab and lobster. While the implementation of data collection programs is essential to provide indicators of the state of commercially exploited stocks, diminishing public resources and an increasing burden of evidence collection has highlighted the need to consider technological solutions as an alternative to traditional methods of data collection.

Currently, for most inshore shellfish fisheries, data collection relies on self-reporting of landings, point of first sale data, port sampling, and on-board sampling by fisheries officers. On-board observers and scientific vessel surveys collect detailed data, but they are expensive and time-consuming. The use of on-board camera systems to collect data has been tested in fisheries targeting shellfish (Hold *et al.*, 2015). Camera systems were found to be a reliable and accurate method for collecting data on the size and sex of crabs and lobsters. Future computer automation of image extraction and measurements should increase the application of video cameras for data collection and ensure a widespread adoption of such data collection systems.

Before it is possible to consider the development of automated software systems to measure animals in the field of view, a reliable mechanism was needed to eliminate errors associated with depth of field linked to the variable distance between the animal and the background reference scale included in the field of view (Hold *et al.*, 2015). The use of parallel-paired lasers coupled to video cameras is a simple and accurate method to obtain precise estimates of animal size from camera images (Cambie *et al.*, 2016).

Bangor University is trialling this technology (cameras with parallel-paired lasers) in the inshore static-gear shellfish fishery in the Isle of Man by having a *sentinel* fleet collect fisheries-dependent video data. The equipment is expected to be installed and operational in early 2017. An evaluation of the technology (benefits and limitations) as well as population assessment results is expected to be available for the next ICES WGCRAb.

5.7 Irish stock of the edible crab (*Cancer pagurus*) and European lobster (*Homarus gammarus*)

5.7.1 ToRs a) and b) Data on *Cancer pagurus* from Ireland

Irish vessels fish for crab in ICES Areas 4, 6 and 7. In 2010 the WG agreed a series of assessment units covering fisheries exploited by vessels from UK, Ireland, France, Norway and Sweden. Four of these assessment units, (Malin, SW Ireland, SE Ireland/Celtic Sea, N Irish Sea) surround the Irish coast and Irish inshore vessels fish in all four units. Landings (tonnes) into Ireland from 2004 to 2015 for these four assessment units and adjacent assessment units by Irish vessels are shown in Table 10. These landings are collated from the operational landings database. Table 11 shows the landings (tonnes) for the under 10 metre vessels that fish around the Irish coast within 12 nmiles of the shore.

The quality of the landings data from the official national databases are variable and may at times reflect changes in the efficacy of recording rather than the crab fishery itself. Landings data for 2016 is incomplete at this time and therefore has not been included.

Size distribution data was collected from the Malin, SW Ireland and SE Ireland/Celtic Sea assessment units during 2015. A total of 7727 brown crab were measured from both at sea and port sampling around the coast of Ireland. The majority (58%) being from the SW Ireland assessment unit. The majority of crab measured were female (83%) in both catch and landings sampling. Female crab from the Malin assessment unit ranged from 132–197 mm carapace width with a mode size of 162 mm, while male crab from the same stock ranged from 118–205 mm carapace width with the majority being 144 mm. In the SW Ireland assessment unit female brown crab ranged in size from 31–226 mm carapace width and males ranged from 41–221 mm carapace width. Both female and male brown crab from the SW Ireland had a mode size of 122 mm carapace width. Female brown crab from the SE Ireland/Celtic Sea assessment unit ranged in size from 121–215 mm carapace width while, males ranged in size from 116–221 mm carapace width. Females from this assessment unit had a mode size of 164 mm and males had a mode size of 153 mm.

No assessment methods are currently being utilised by Ireland on the four stocks/assessment units around the Irish coast.

Table 10. Landings (tonnes) by assessment unit of *Cancer pagurus* by Irish vessels from 2005 to 2015. Data is based on operational data from logbooks and does not include landings from under 10metre vessels. ('Outside' refers to landings caught from outside the assessment units agreed upon at WGCRAb 2010 and 'Not Recorded' refers to landings where the ICES Rectangle was not recorded).

5.7.2 ToRs a) and b) Data on *Homarus gammarus* from Ireland (provided by the Marine Institute of Ireland)

The Irish fishery for lobster (*Homarus gammarus*) occurs all around the coast. Landings (tonnes) into Ireland for 2014 and 2015 are shown in Table 12. These landings are collated from the operational landings database. The landings for the under 10 metre vessels are also included.

The quality of the landings data from the official national databases are variable and may at times reflect changes in the efficacy of recording rather than the crab fishery itself. Landings data for 2016 is incomplete at this time and therefore has not been included.

Table 12. Landings (tonnes) by ICES Area (where possible) of *Homarus gammarus* by Irish vessels in 2014 and 2015. The offshore data is based on operational data from logbooks. Landings from the under 10metre vessels is also included and makes up the majority of the landings listed.

SW Ireland	55.40	185.01
SW Ireland - SE Ireland	25.09	45.01

Along with the conservation measures of a minimum size limit (87 mm Carapace Length) and a v-notching programme (it is not obligatory to v-notch lobster but it is illegal to land a v-notched lobster) a maximum size limit (MSL) of 127 mm was introduced on both male and female lobsters in January 2015. This MSL was designed to have a number of effects on the lobster population over time:

- a) Establish size classes of lobsters above 127 mm which are currently weakly represented in the population generally.
- b) Increase egg production by large lobsters and, when combined with v-notching, bring egg production per recruit in the population over 10% of what it would be in an unfished stock.
- c) Maintain the male:female sex ratio in large lobsters at a level that is present in lobsters below 127mm.

A maximum size limit of 127 mm was chosen as previous studies on historic landings data indicated that lobster ≥ 127 mm represented approximately 3% of the lobster caught around the coast and therefore would not have a significant economic impact on the fishery. Its effects on egg production were assessed using an egg per recruit model and although it was not very beneficial by itself when combined with high v-notching rates a significant component of lobsters above 127 mm will benefit from permanent protection.

Size distribution data from 8,495 lobsters was recorded around the Irish coast between April and November in 2015. Table 13 indicates the quantity of lobster measured from 15 sampling locations around the coast.

Table 13. Total quantity and proportions of lobster <87 mm, ≥87 mm<127mm, ≥127 mm (with v-notch), ≥127 mm (no v-notch) and v-notched sampled at sea at various locations around the Irish coast during 2015.

Location	Total	% <87mm	% ≥87mm<127mm	% ≥127mm (with v-notch)	% ≥127mm (no v-notch)	% V-notched

Waterford	1,355	58.75	40.37	0.59	0.30	2.95
Wexford	1,797	47.91	50.75	0.22	1.11	1.11
Dublin	281	73.31	26.69	0.00	0.00	0.36
Dublin offshore	357	3.64	90.76	0.00	5.60	1.68
Louth	87	55.17	44.83	0.00	0.00	0.00

The proportion of lobster equal to or above the maximum landing size of 127 mm varied around the coast and ranged from 0–10.53 %. However at the majority of locations catches of MaxLS lobster represented less than 3% of the total catch. North Donegal returned the highest proportion (10.53 %) of lobster ≥127 mm. These vessels were targeting brown crab and were predominately fishing off the coast in deeper water and thus were not fully representative of the Irish lobster fleet in this area.

A high proportion (5.6%) of MaxLS lobsters were also recorded offshore from the Dublin coast. Again these vessels were fishing in deep water and approximately 96% of the total lobster catch in this area was over the minimum landing size with 1.7% being v-notched. In comparison less than 30% of lobsters caught closer to the coast of Dublin were ≥87 mm and none of these were ≥127 mm.

To the north of the Dingle peninsula 35% of the lobster caught were ≥87 mm while less than 2% were oversized. However to the west of the Dingle peninsula 64% of the lobster caught were 87 mm or over and 4.7% were ≥127 mm. In this area 1.24% of the lobster catch was previously v-notched while no v-notched lobsters were recorded from catches to the north of the peninsula.

Oversized lobster ≥127 mm made up 3.23% of catches off the south western Cork coast. In the same area only 41.4% of the catch was ≥87 mm and 1.08% was v-notched. In com-

parison only one lobster caught outside Cork Harbour was above the maximum landing size and only one had been previously v-notched.

5.8 French stock of the edible crab (*Cancer pagurus*)

5.8.1 ToRs a) and b) Stock status of brown crab in France

The French landing of brown crab is quite stable for 15 years now. The annual fluctuations are not too high and the landing is around 5500 tons per year (Figure 10). Since 2003, the number of vessel which are involved in this fishery is quite stable. The decreases in 2009 and 2010 are linked to the change in the way to store the data and a bad situation where many logbooks and fishing sheets have been lost. For the last year, all the data are not yet recorded it is why the landing seem lowest.

Figure 10. Total landing and number of vessel in the fishery.

The landings are mainly due to two fleets, the potters (caseyeurs) and netters-potters (fileyeurs caseyeurs), which represent close to 80% of the total landing (Figure 11). For this last fleet, the brown crab is targeted using classical pots for 97% of the landing. In these two fleets, the fishing strategy is not the same according the vessels. In fact, only few vessels are very dependant to brown crab where they achieve more than 50 % of the turnover thanks to this species (Figure 12). The number of these vessels is not more than 20 vessels. From these 20 vessels, 12 are offshore potters or "vivier" vessel which land close to 50 % of the total French landing. These 20 vessels are really dependent of the status of the stock but in a first place from the market where the price per kg is quite low.

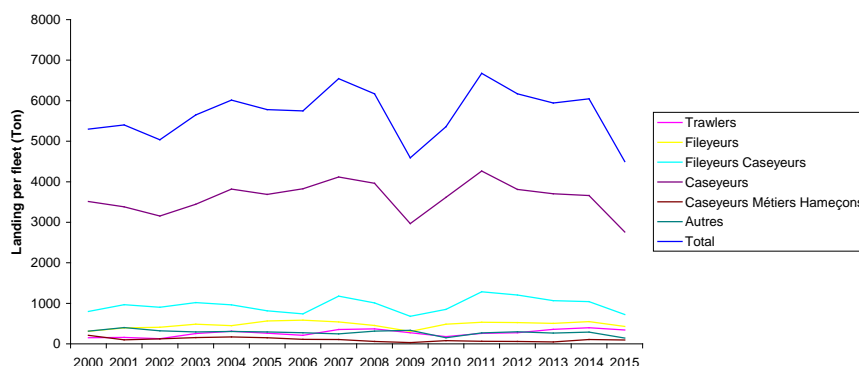

Figure 11. Annual French Landing per Fleet for the brown crab.

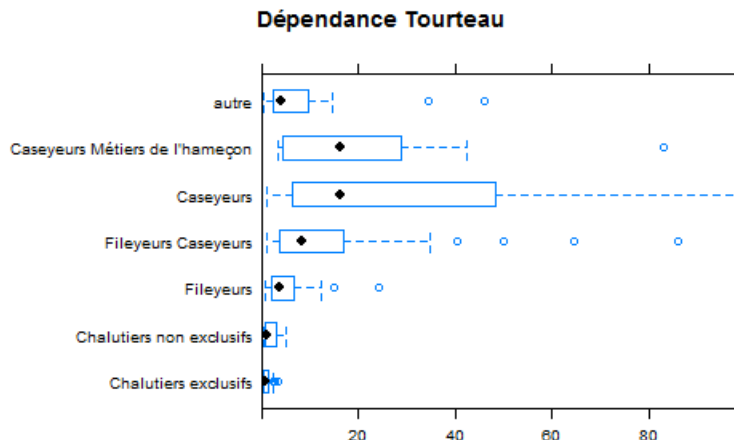

Figure 12. Boxplot of the individual turnover related to the landing of brown crab for the different fleets.

For the other fleets involved in the fishery, the brown crab is more considered as bycatch. As example, for the netter fleet which target flat fishes as turbot or monkfish, brown crab is really a bycatch, even if it can represent a turnover close to 10 % (Figure 12).

The fishery of the brown crab is seasonal (Figure 13, 15a, 15b). In a fishery where 80 to 90 % of the landing are some females, the catchability has a great importance. The berried female stays in the sand for 5 month (November to April) where the landing decrease a lot. During this period, some vessels stop to fish and other vessels change their strategies, looking for lobsters, shrimp or whelks. At the same time, the better fishing ground for brown crab are far from the shore and during winter these areas are not easily accessible due to the weather conditions.

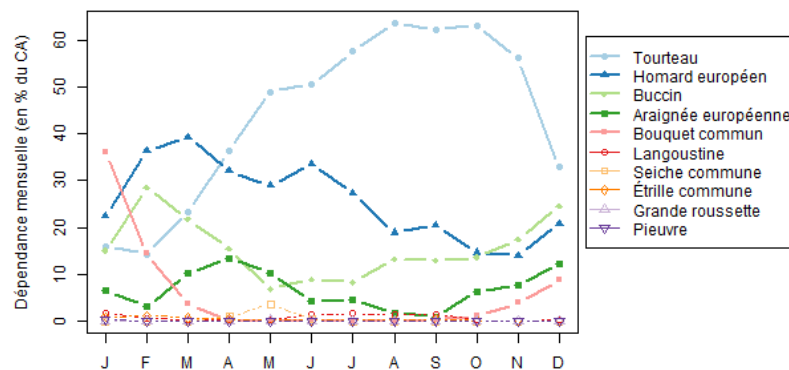

Figure 13. Part of the different species in the monthly turnover for the potter fleet.

The vessels which land brown crab come from Brittany (Figure 14) in a large part and from Normandy after. For the rest of the coast, some vessels land crab too but in a lowest proportion. There is really a fishing culture to target brown crab which is found a lot in Brittany, for the administrative areas from SM to SN.

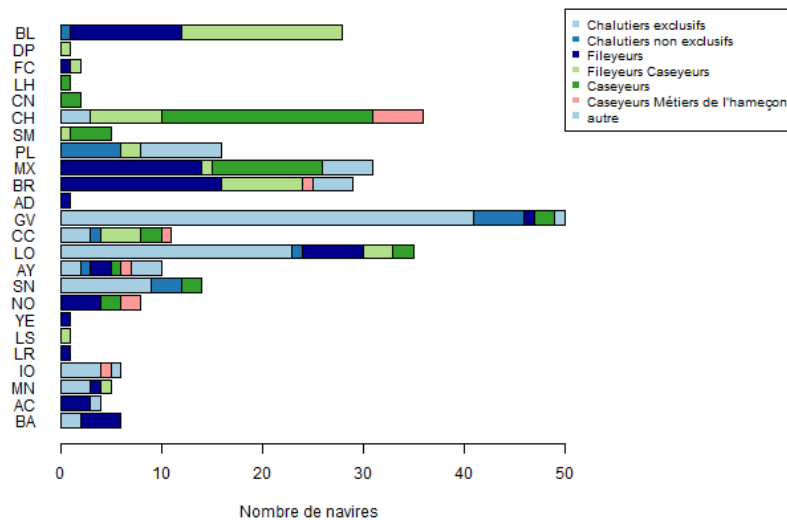

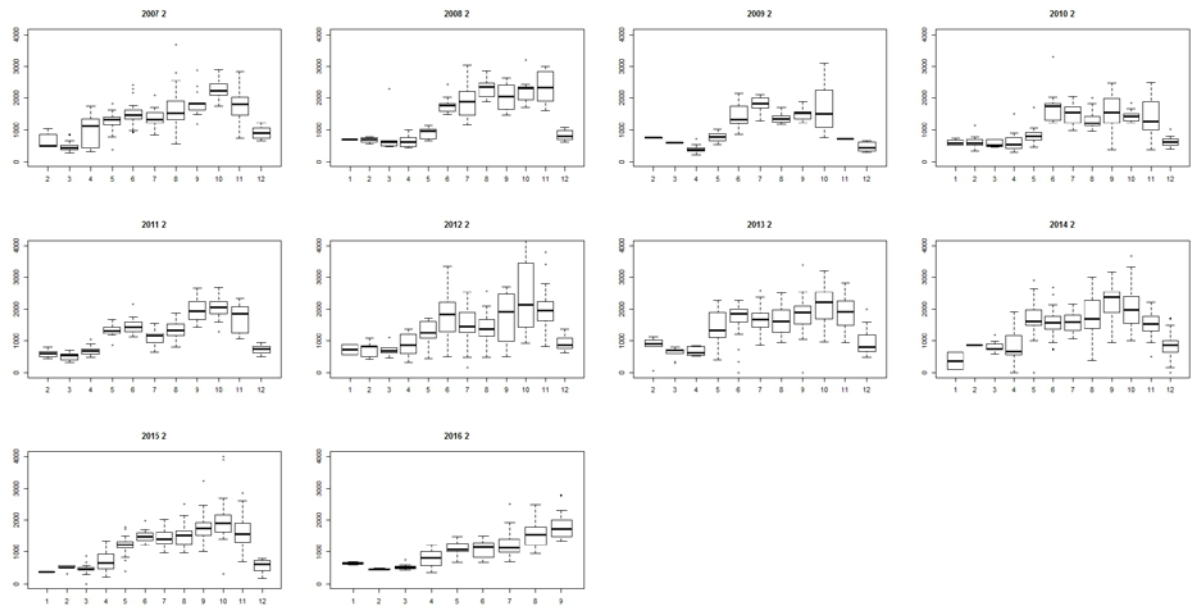

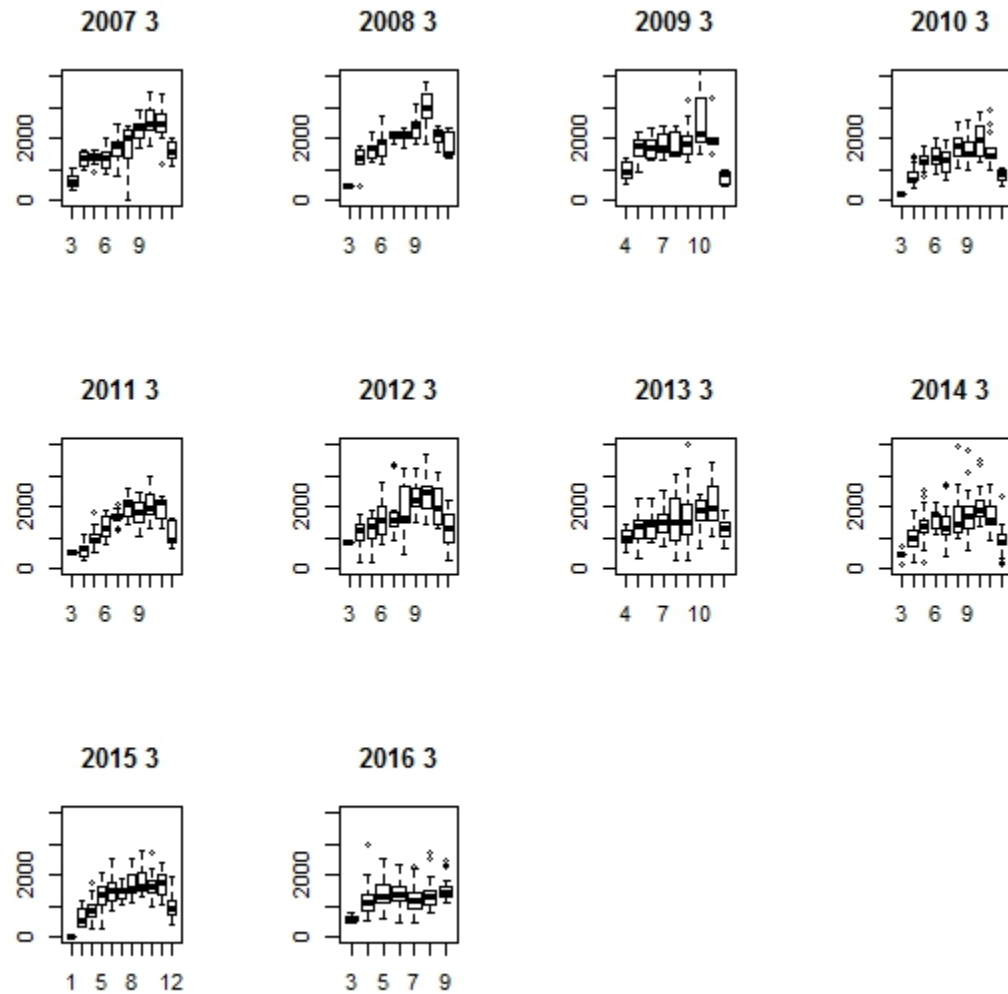

Figure 14. Repartition of the vessels which land lobster in administrative areas.

Thanks to the declaration data available now, the development of abundance index for some areas of the fishery can be performed from LPUE data. This work has been done for the two main landing areas, Western Channel and Bay of Biscay. This work is only developed from the offshore vivier vessels.

6a)

6b)

Figure 15b: Monthly LPUE (kg/1000 pots) for the two main fishing areas, 15a (Western Channel), 6b (Bay of Biscay).

From these data, the seasonality is well observed with very low abundance in winter. After, the general trend is really an increase with the highest value in autumn. The abundance is a little higher in Bay of Biscay compared to Western Channel. Using all the data, a glm model is developed to estimate an index abundance where the effects year, month, area and vessel are retained. All these effects are significant and they are used to estimate an annual index. With the time series available, the abundance index estimated clearly shows a great stability for the last 30 years (Figure 16). From 1990 to 2016, the index increases slowly with some annual variations. The data for 2016 are not completely available for October and November. It is why the final situation will be better for the two main areas.

In the western Channel and the Bay of Biscay, where the French vessels are active, there is very few other foreign vessels. Moreover, the management rules in place for the French vessels allow to stabilize the fishing effort. This point is really important to understand the good level of the abundance index.

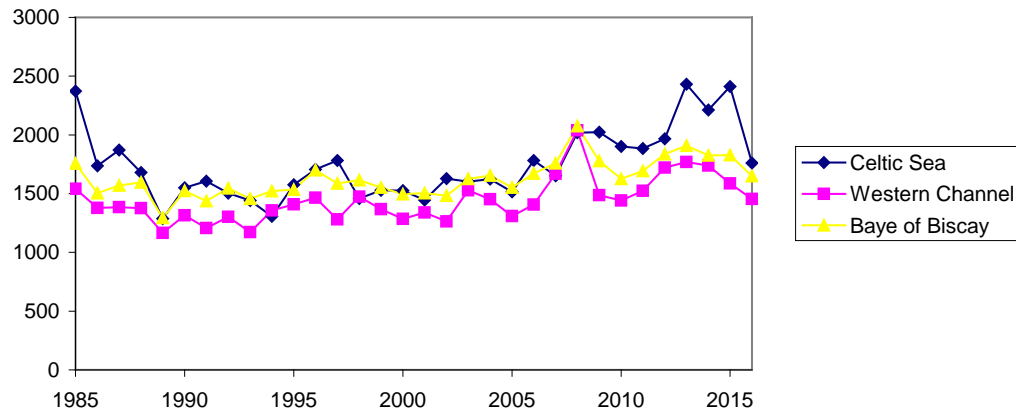

Figure 16. Abundance Index for the three main fishing areas (kg/1000 pots).

5.9 French stock of the lobster (*Homarus gammarus*)

5.9.1 ToR a) and b) Stock status of lobster in France

The French lobster fishery is located in a large part of the atlantic and channel coast. From Boulogne sur Mer in the north part to Oleron island in the south, lobsters are found in different types of rocky ground mainly in coastal water, less than 40 meters depth. In all harbours neighbouring these areas, some vessels target lobster. Nevertheless, their number is really variable along the coast. The two main areas are in the north of Brittany and the west of Normandy (Figure 17).

The French production for 15 years increases steadily to reach today around 550 tons (Figure 18). At the same time, the number of vessel increase also but in a lower proportion. We can really say that the evolution during the period from 2000 to 2005 is linked to the increase of declarations. In fact from 2000, all the vessels, for each size, have to declare their production and activity. For the vessels under 10 meters, a national fishing sheet is used as equivalent to the European logbooks.

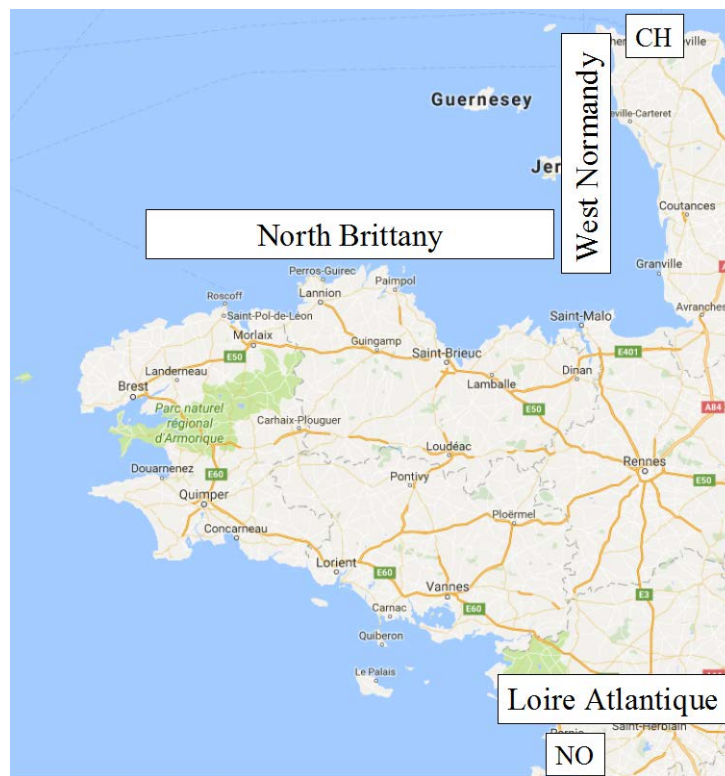

Figure 17. Map of the main lobster fishery and position of two administrative areas (CH and NO).

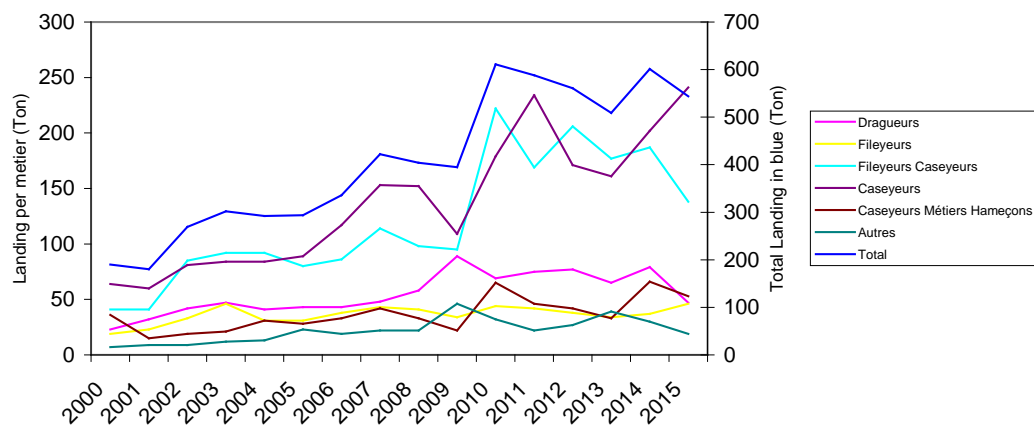

Figure 18. French landing of lobster per fleet from 2000 to 2015.

In the times series, the years 2008 and 2009 should be analysed with caution. A change in the national database has generated some errors or misses. It is why, we can estimate that the total production for these two years is upper than these official values. The two main fleets are the potters (caseyeurs) and Netters/Potters (Fileyeurs Caseyeurs) which repre-

sent around 70% of the landings (Figure 18). In the second fleet, the pot is really the gear used to target lobster. So, for these fleets, the lobster pot "métier" is largely used.

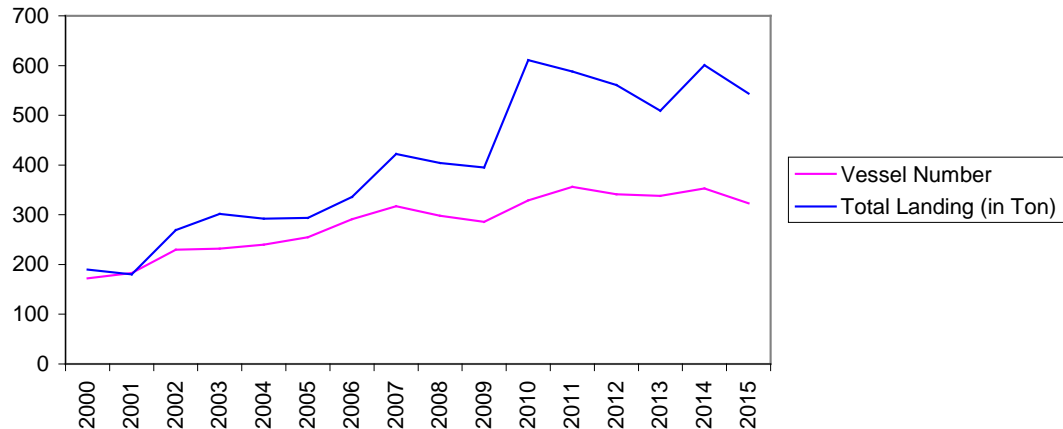

Figure19. Total French Landing and number of vessel involves in the fishery from 2000 to 2015.

Looking the trend in the number of vessels, an increase appears from 2000 to 2007 (Figure 19). One part of the increase has to be linked to the improve of the declaration by the fishing sheets. After 2007, the vessel number is more stable. This stabilisation is explained by the manage rules in place where the number of vessels are contained by licence quotas in each region. As associated rule, the number of pot per vessel is fixed with a maximum of 200 by fisherman in board. These rules have allowed to control the evolution of the fishing effort. At the same time, the respect of the minimal legal size year after year have lead to the good evolution of this fishery. The repartition of the vessels along the coast clearly shows that the two fleets which land the lobster are more abundant in Normandy and North Brittany (CH to NO) and the large part of the landing come from these areas (Figure 17 and 20).

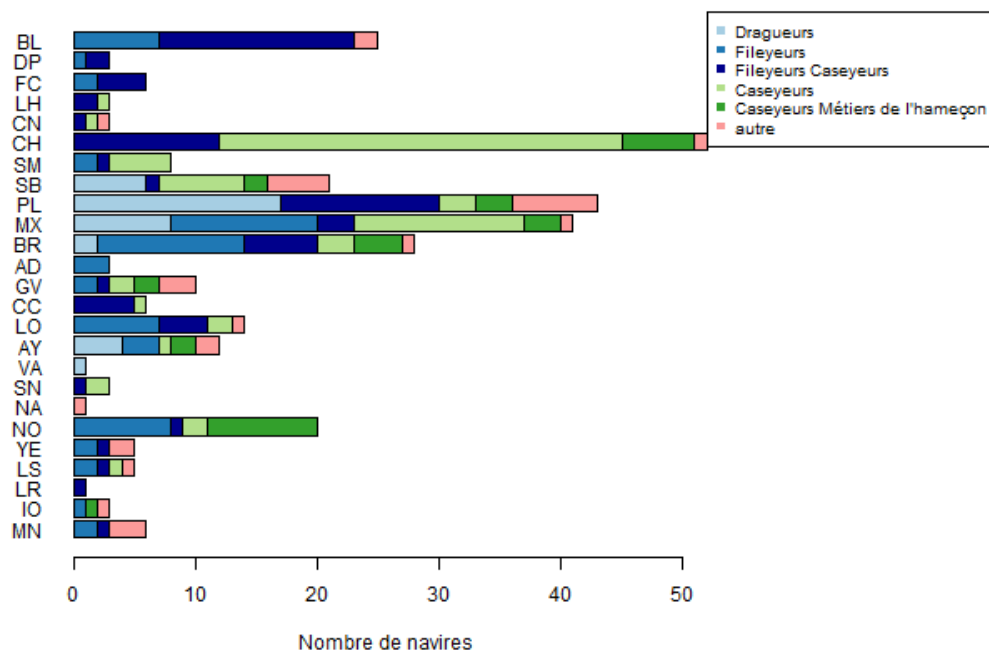

Figure 20. Repartition of the vessels which land lobster in administrative areas.

Thanks to the declaration data available now, the development of abundance index for some areas of the fishery can be performed from LPUE data. This work has been done for the two main landing areas, North Brittany and west coast of Normandy, where all the data linked to the pot activity are selected.

The LPUE clearly increase at the end of the winter to reach a maximum in June (Figure 21). The decrease in July is associated with the moult of many lobsters and a lower availability. After, in August the LPUE level increase at a level similar to June. From the end of summer to the end of autumn, the LPUE decrease in a large proportion. This evolution of the capturability seems to be associated to the temperature of the ocean, where the catchability increase with the sea temperature. One particularity seems to validate this link. In 2013, the LPUE are lowest in April at the end of a period where the sea temperature has decreased until the 14 of April. This seasonality of LPUE observed from one area in Normandy is found in all the areas along the coast.

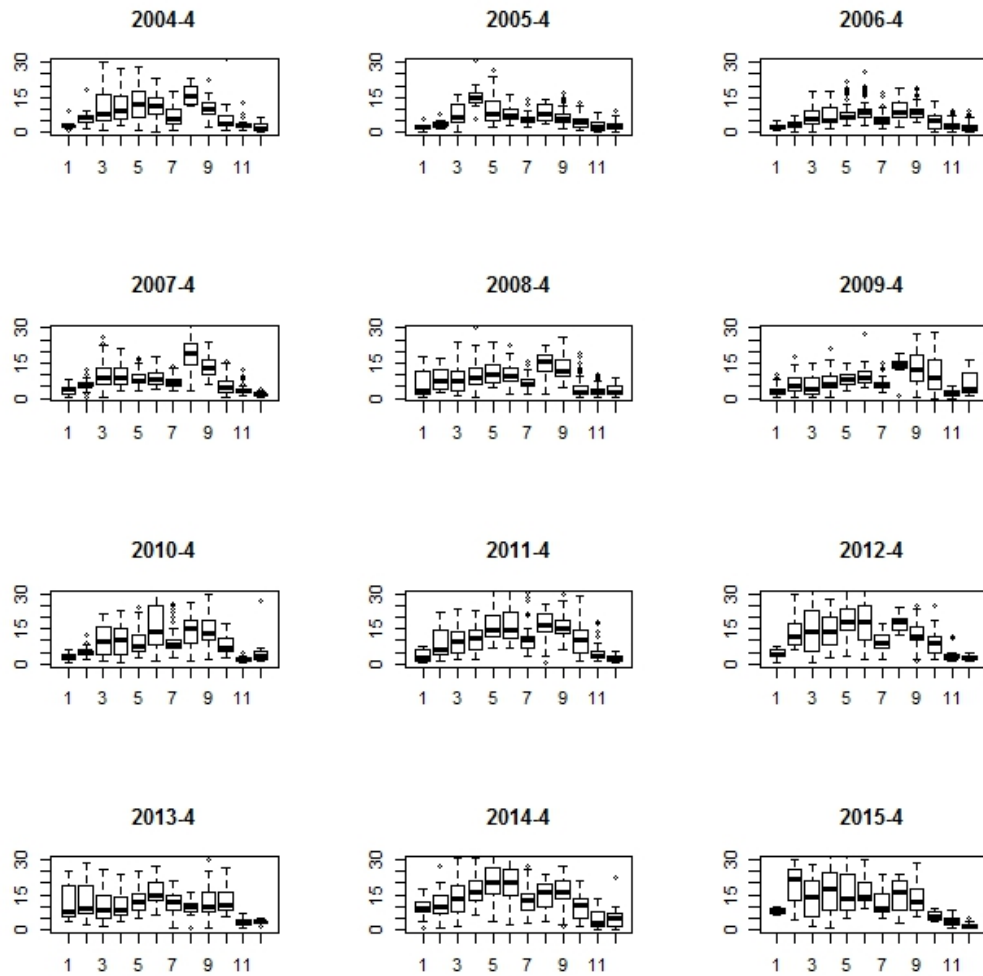

Figure 21. Seasonal evolution of the LPUE in one area of the west Normandy Coast from 2004 to 2015.

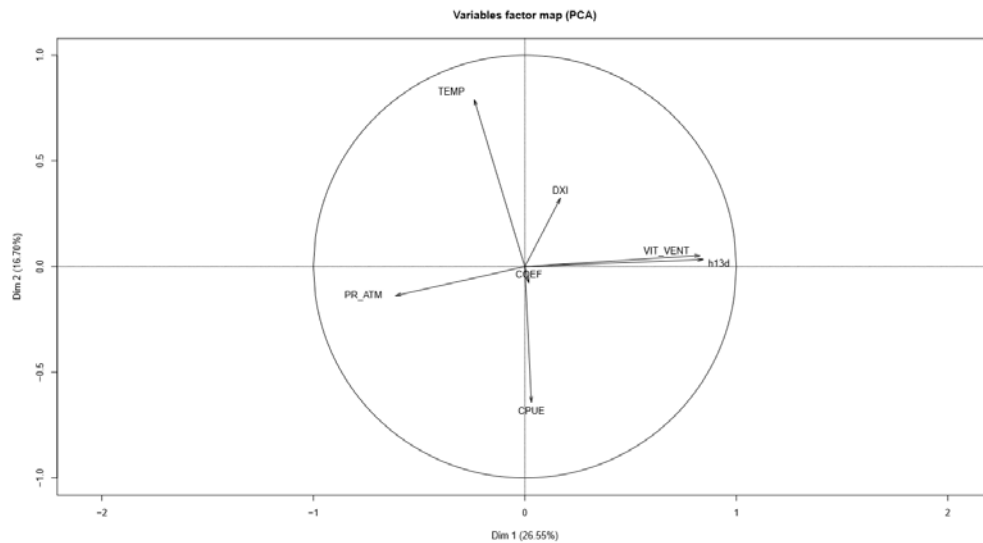

Figure 22. Factorial analyse of environment parameters explaining the LPUE values.

From many parameters of the environment, the temperature seems to impact wide the evolution of the LPUE as showed in this first ACP result (Figure 22). This result comes from three areas where daily time series of LPUE, temperature, swell and wind have been tested.

To develop the index, we have selected for the two areas (West Normandy and North Brittany), the vessels which really target lobsters during a large part of the year. The considered index is the daily landing for 100 pots (LPUE). The index comes from a GLM model where the following effects are selected: individual vessels, year, month and area.

From the two main landing areas (Figure 23 and 24), the trend of the index is really equivalent, steadily increase since 2005. There are some annual evolutions, but the general situation clearly shows an increase of the abundance.

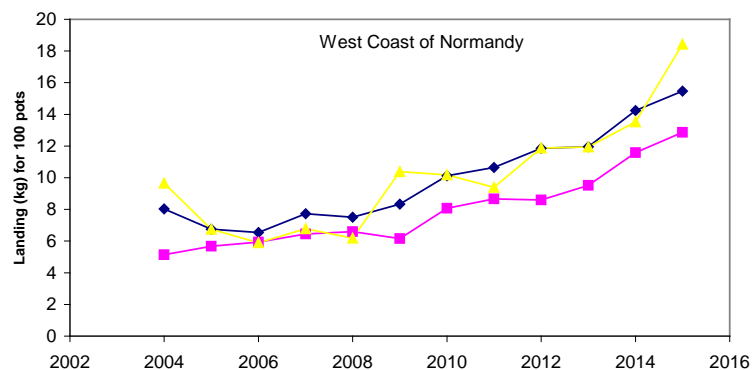

Figure 23. Index abundance for three areas in the West Coast of Normandy.

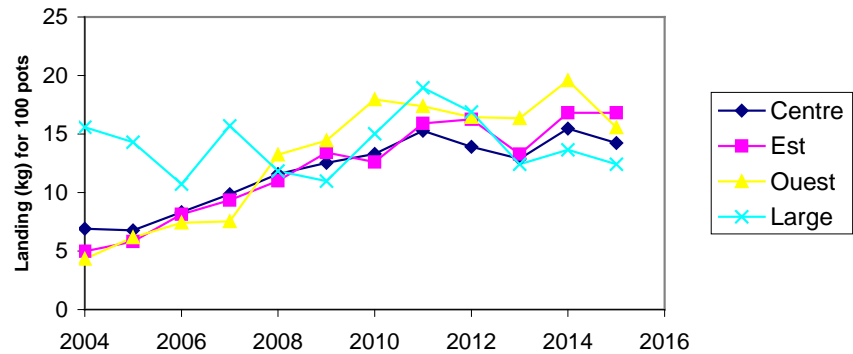

Figure 24. Index abundance for four areas in the North of Brittany.

At the boundary between the south east part of Brittany and Pays de Loire Region, in a less important lobster area in considering the landings, the evolution of the LPUE, without application of a model, shows similar trend over the last 10 years.

The works on the lobster fishery have to be improved with a largest study integrating all the areas along the French coast, where abundance indices will be associated with stock assessment models. At this stage, many data are put in place in order to be able to develop all these assessments. Nevertheless, the current situation is really positive and some discussions propose to apply more conservative management rules as increase the MLS to 90 mm LC. The negative impact will be short in the current good situation, but the positive impact at long term will be interesting.

5.10 Norwegian stock of King crab (*Paralithodes camtschaticus*)

5.10.1 ToR b) Status red king crab (*Paralithodes camtschaticus*) in Norwegian waters

The harvest of the red king crab (*Paralithodes camtschaticus*) in northern Norway has a fishery history for 22 years now. Present management regime was established in 2008, and have since then been primarily a male-only fishery, but there is also an additional small quota on female crabs. In the dual management regime there is two goals, one is to maintain a long term commercial harvest in a limited geographical area with total allowable catch (TAC) and restricted participation (East Finnmark). The other goal is to limit further spread of the crab and minimize crab abundance outside the commercial area (West Finnmark). There is also a profitable fishery going on in West Finnmark, and it is used as tool to fulfill the goal reducing the

The Institute of Marine Research carry out two annual cruises in the quota regulated area to assess the stock and advising on harvest. In addition, we perform a trap survey in coastal areas west of the quota regulated area to monitor the spread of the crab. After six years of surveillance, it seems that the free fishery is able to limit the rate of spread, and keeping the stock at low levels in areas where the crab is established.

During the last eight years the landings of the red king crab in East Finnmark has been stable. About 550 fishermen can participate in the fishery and the value of the landings

has varied between 100 to 250 million Norwegian kroner. The landings in West Finnmark has varied more due to that the variance in effort, nevertheless the first hand value of the landings has varied between 13 to 87 million Norwegian kroner, and in average about 200 boats participate.

We are presently emphasizing improvement of logbook data from the fishery. This will give us knowledge about fishery pattern such as catches, fishing depths and effort.

Data collected on the red king crab surveys are analyzed using a compound production model. This model provides alternative harvest options with affiliated risk analysis. The quota has been stable and varied between 1000 to 2000 tones the six last years.

5.11 Norwegian stock of Snow crab (*Chionoecetes opilio*)

5.11.1 ToR a) Status on the snow crab in the Barents Sea

The snow crab (*Chionoecetes opilio*) stock has increased rapidly both in distribution and abundance in the Barents Sea since the first five specimens were found in 1996 at the Goosebank in south eastern part of the Barents Sea. The population is expanding its distribution primarily westwards and northwards into the Norwegian zone.

The snow crab is therefore now found in large parts of the Barents Sea, but still the largest part is in Russian exclusive economic zone (EEZ). The snow crab is defined as a sedentary species, which entail several challenges regarding management of the species. The Barents Sea continental shelf, including the Loophole, belongs to Russia and Norway. The border Norway and Russia agreed upon in 2010 lined up the dividing of the continental shelf between the two Parties. This implies that most of the Loophole continental shelf belongs to Russia and it also implies that it is only Norwegian and Russian registered ships that can participate in the fishery until other management arrangement has been developed.

At present, most of the snow crab fishery in the Barents Sea takes place central in the Barents Sea. There has been a fishery for snow crab in the Barents Sea for five years. It started with only small landings of 2.5 tons in 2012 and so far, in 2016 there is landed around 4600 tons. In total there is landed almost 9400 tones snow crab at Norwegian harbors from both Norwegian and foreign ships. The first hand value of the snow crab was about 250 million Norwegian kroner in 2015.

Norwegian data on the snow crab stock in the Barents Sea originate mainly from by-catches in the regular routine cruises conducted by the Institute of Marine Research using a multispecies trawl in August. We have therefore some knowledge about the stock structure and basic biological parameters for the Barents Sea snow crab.

A management proposal has been prepared and are under development and will be released in near future.

5.12 Greenlandic stock of Snow crab (*Chionoecetes opilio*)

5.12.1 ToRs a) and b) Stock Summary of snow crab in Greenland waters

Regulations

Snow crabs are distributed along the West coast of Greenland and are commercially exploited primarily from Disko Bay in the North (up to 71° 30N) to Paamiut in the South (60° 45N). Commercial fishing for snow crab began primarily in inshore areas (within basis-line) in the mid-1990s and from 1999, also included offshore areas (outside basis-line).

Since 2004, the crab resource in Greenland has been managed in 6 areas (from North to South - Upernavik, Uummannaq-Disko Bay, Sisimiut, Maniitsoq-Kangaamiut, Nuuk-Paamiut and Narsaq-Qaqortoq, Figure 1). The fishing fleet is made up of two components; small vessels (less than 75 GRT), which have exclusive rights for fishing inshore within the basis-line as well as offshore. Small vessels are, however, restricted to fishing in only two management areas during the year. Large vessels (greater than 75 GRT) may only fish in all offshore areas (outside the basis-line), but not within the "Crab Boxes". Quota restrictions have been imposed to each of the 6 management area since 1995 and individual quotas to vessels larger > 75 GRT, but have only limited the catch in 2004. Management decisions allow increasing quota in each of the six management area, when the catch achieved the first fixed quota. Unused quota from larger vessels is re-allocated to the inshore fleet (small vessels < 75 GRT). Basically, there is now quota restriction for the small vessel. The fishery is regulated by prohibitions to land females and undersized males (<100 mm CW), logbooks for all vessels larger than 10 meters and closure of the fishery north of 64°N for 3 months (1 January to 31 March).

Objective of recommendations in Greenland

There are no specific long-term management objectives for the snow crab resource in West Greenland, however since 2004 the main objective of recommendations from GINR has been to stop the decline in biomass of the crab resource in the different management areas. The recommendations are not expected to result in increased stock biomass in the short term, but only stop the current decline. If a rebuilding of the stock to achieve a higher exploitable biomass and better catch rates is the objective, then the recommended catches should be further reduced to allow the stock to grow.

The fishery

The historical development of the crab fishery in Greenland is shown in Figure 25 and Table 14. Landings increased from approx. 1000 tons in 1995 to a peak of approx. 15 000 tons (Quota 26 800 tons) in 2001. Since landings as well as quota has been markedly reduced. From 2001 to 2007 total catch declined by approx. 89% to 2189. In the subsequent years landings has been stable at approx. 2.100 tons and total landings was 2.021 tons in 2015.

Landings within each of the management areas have varied over time (Figure 26) and in 2015 80% of total landings were taken in Management area Sisimiut and Nuuk-Paamiut, whereas the contribution from the other management area very limited.

The total fishing effort (trap hauls) has declined by 91% since 2001 (from 3416 to 319 thousand trap hauls during 2001–2012); (Figure 26). The decline in fishing effort has been mostly due to a declining number of participants in the fishery.

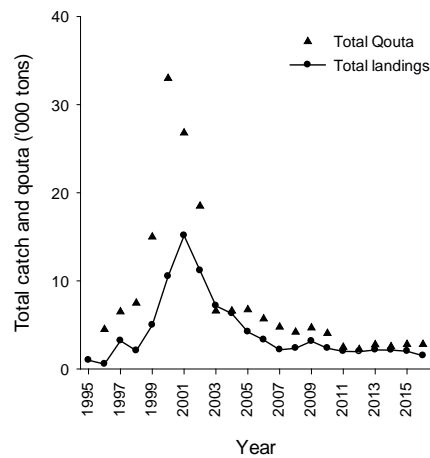

Figure 25. Total catch and quota size from 1995–2016. Data from 2016 is preliminary and incomplete.

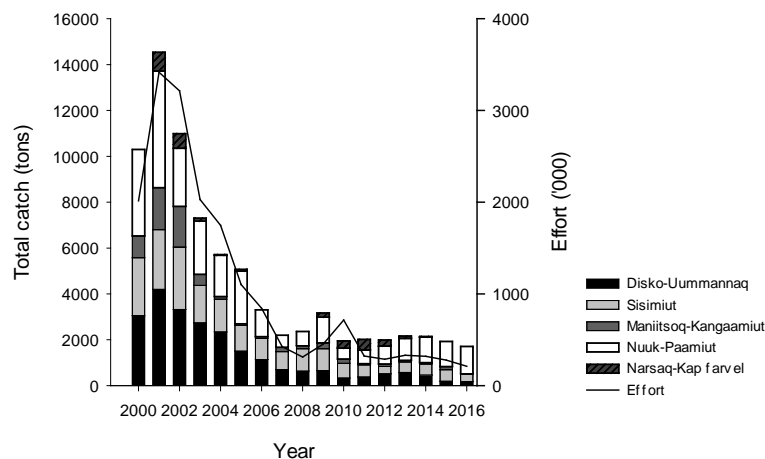

Figure 26. Snow crab landings in the four most important management areas of West Greenland 2000–2016 and used total effort. Data for 2016 are preliminary and incomplete.

Stock status

The accumulated biomass available to the fishery in 2017 is highly variable according to the stocks indices. Generally, in 2016, stocks in each management area along the west coast of Greenland were characterized a low level in the management areas of Disko Bay inshore and Sisimiut offshore, butd as stable commercial biomass in management area of Sisimiut inshore and Nuuk-Paamiut offshore. Recommendations for 2017 are status quo

in terms of TAC in all areas. In Sisimiut management area the offshore site were recommend close until the stock rebuild.

Management area Uummannaq – Disko Bay

Landings declined by 88% from 4202 t in 2001 to 188 t in 2015, while effort decreased by 96% (Figure 27 and Table 14). The exploitable biomass has been declining the past 3 years in Disko Bay inshore, but have been stable offshore at a low level. Recruitment, based on research data from 2015, has decreased since and is expected to be low over the next several years. In the Northern part of the management area recruitment decreased significant over 2017.

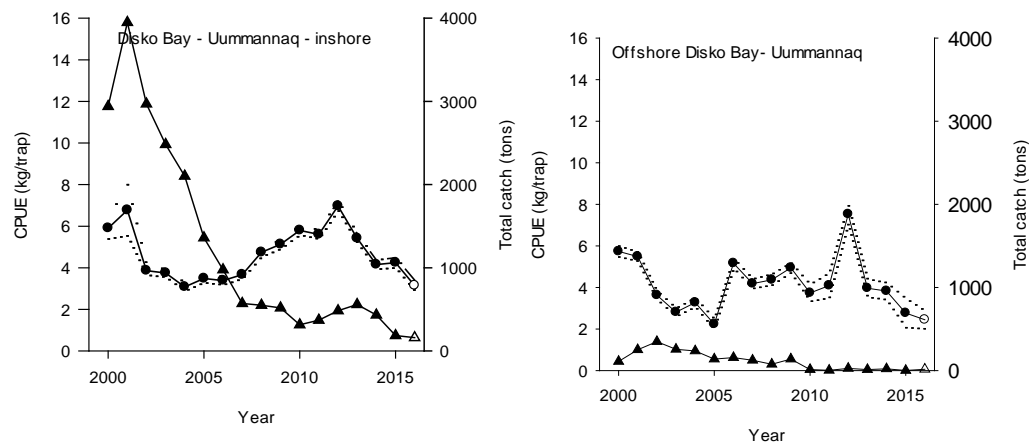

Figure 27. Standardised CPUE index and total catch based on logbook information inshore Uummannaq-Disko Bay Area from 2000–2016. Data for 2016 is preliminary and incomplete. (● is standardized CPUE, ▲ total catch and dotted line lower and upper confidence limits).

Management area Sisimiut (inshore and offshore)

Inshore landings declined from 1111 t in 2004 to 312 t in 2015 (TAC 300 t in 2015), while effort decreased by 93% (Figure 28 and Table 14) CPUE steadily increased since 2012. Offshore landings declined significantly from 2275 tons to 196 t in 2015 and CPUE remain high as a result of a huge decline in effort in the same period. The exploitable inshore biomass declined significantly inshore as well as offshore from 2009 to 2011, increased in 2012 and have remain stable as a level close to its serial mean in Sisimiut inshore, but remain low in Sisimiut offshore, except for an increase in biomass in 2015 (Figure 29). Recruitment decreased in 2009, as was especially for the offshore site reflected by the abrupt decrease in exploitable biomass while landings increased little (Figure 30). Inshore, recruitment has fluctuated since 2012 at a low level and recruitment is expected to be low in near future, but longer-term prospects remain uncertain.

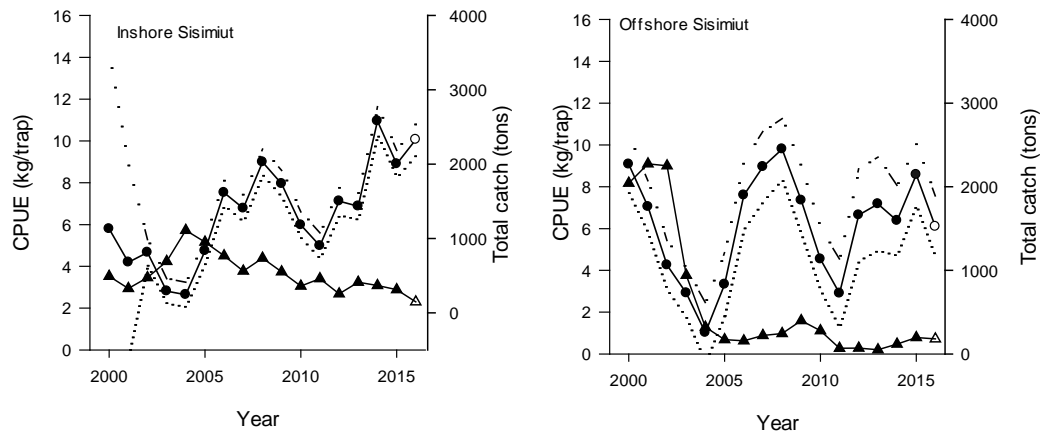

Figure 28. Standardised CPUE index and total catch based on logbook information inshore and offshore Sisimiut from 2000–2016. Data for 2016 is preliminary and incomplete. (● is standardized CPUE, ▲ total catch and dotted line lower and upper confidence limits).

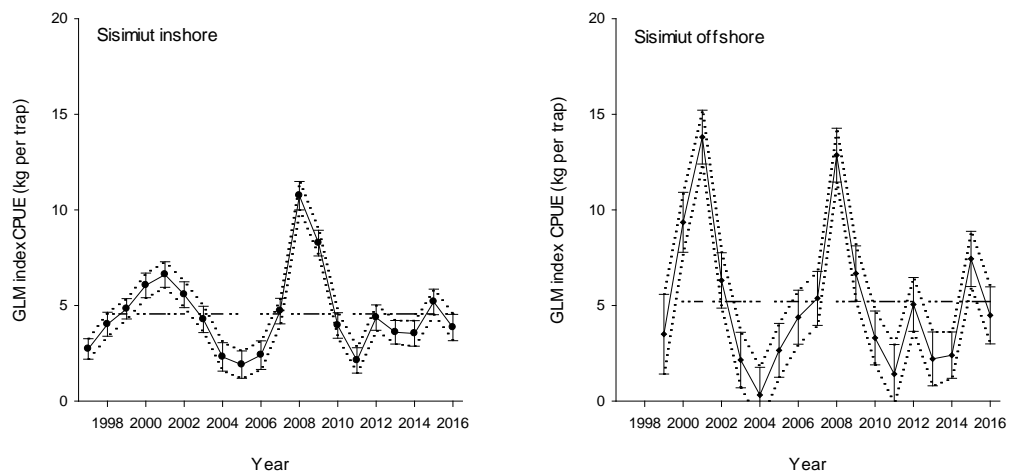

Figure 29. Annual trends in exploitable biomass (kg/trap \pm S.E.) of legal-size males (≥ 100 mm CW) from trap surveys in Sisimiut in- and offshore from 2000 to 2016. ●: CPUE (kg/trap) and dotted line is lower and upper confidence limits.

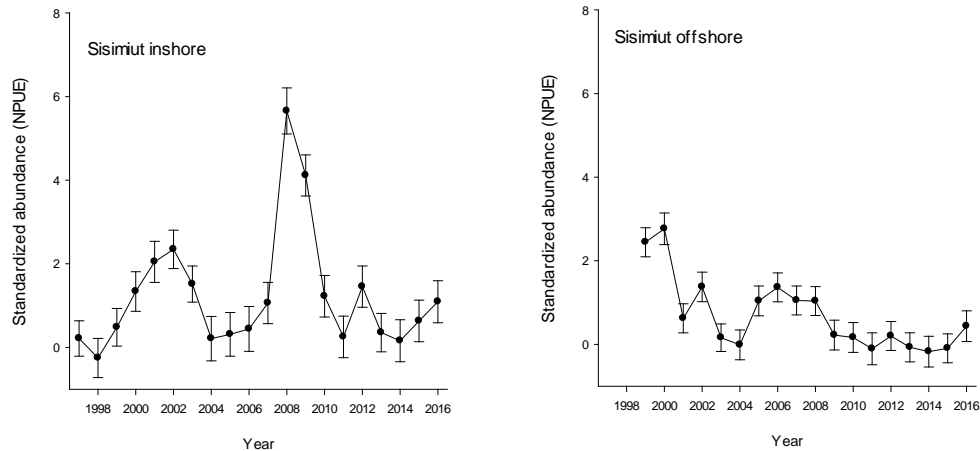

Figure 30. Recruitment index (ADO-1: 82.2 – 100 mm CW) of adolescents males from the annual trap survey in the inshore and offshore sites of Sisimiut management area, 2000–2016.

Managemnet area Maniitsoq – Kangaamiut

Landings and effort have steadily declined since 2002 to a historical low level in 2014. However, landings increased in 2015 (Table 14). No biological survey is conducted in that management area.

Management area Nuuk–Paamiut (inshore and offshore)

Landings declined by 91% from 5077 t in 2001 to 470 t in 2010, while effort decreased by 92% (Figure 31 and Table 14). Since landings increased, especially in the offshore area. The exploitable biomass is considered stable in both inshore and offshore areas. No biological survey is conducted in that management area.

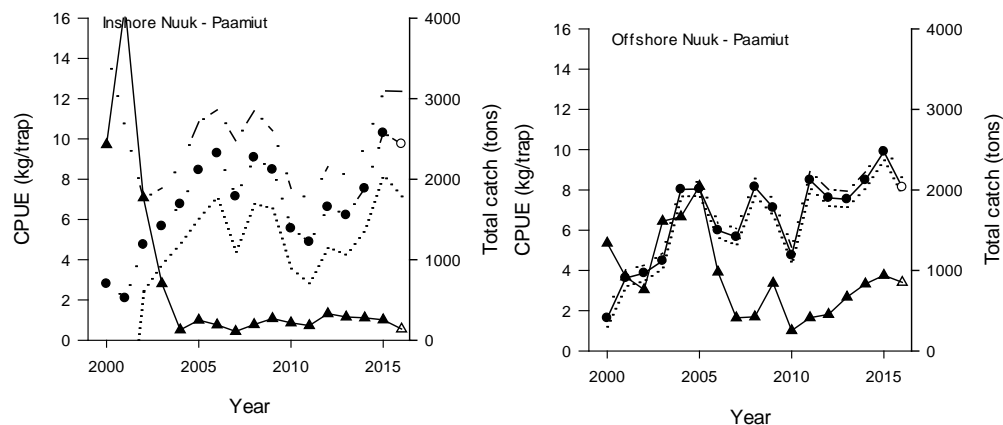

Figure 31. Standardised CPUE index and total catch based on logbook information inshore and offshore Nuuk-Paamiut from 2000–2016. Data for 2016 is preliminary and incomplete. (● is standardized CPUE, ▲ total catch and dotted line lower and upper confidence limits).

Managemnet area Qaqortoq – Kap Farvel

Landings and effort have steadily increased since 2009 from 187 tons to 450 tons in 2011, followed by a significant drop in landings to 268 tons in 2012 (Table 14). Since 2014, there have been no fishing activity for snow crab in this management area. No biological survey is conducted in that management area.

5.12.2 ToR e) Snow crab research in Greenland

A research project proposes to study some aspects of the reproductive potential of snow crab in the coastal waters of West Greenland. Fisheries exploited and non-exploited stocks will be compared as well as populations in hydrographical systems subject to different temperature regimes. Various life history traits will be examined and related to reproductive potential at three study sites along a latitudinal gradient: Disko Bay (north), Sisimiut (middle) and Nuuk (south). The goals of this project are to better understand the reproductive potential of the snow crab, as it relates to temperature conditions and fishing pressure, and to provide essential baseline information for adaptive management and conservation strategies. What is very unique about this study is the possibility of investigating life history traits of an unexploited population of snow crab, something non-existent elsewhere in the world. There are four components to this study. The effects of temperature and exploitation on snow crab population dynamics and – especially – on reproductive potential are multifaceted, complex and possibly synergistic.

Table 14. Landings, CPUE and effort by five management areas at West Greenland waters, 2000–2016.
Data from 2016 is preliminary.

5.13 Canadian stock of Snow crab (*Chionoecetes opilio*)

The Atlantic Canada snow crab presented at the 2016 as well as over the past three years have directly addressed ToRs A, D, and E. Data on fishery and survey statistics have been presented (ToR A). Information on the impact of climate on crab productivity has been presented (ToR D). Finally, studies revealing novel information on snow crab behaviour and life history attributes including ocean climate effects on stage-specific distribution and growth as well as migration behaviour have been presented (ToRs D and E).

6 Summary of Working Group self-evaluation and conclusions

OUTCOME

- The WGCRAb have to update and provide data and knowledge on landings, fisheries and biology of the important crab and lobster stocks in the ICES area. In addition, essential objectives has furthermore been to discuss important crab and lobster stocks and to identify gaps in assessment programs and review application of biological and management reference points for crab fishery. The WG also reviewed alternative indicators in assessment of crab stocks without fishery independent data. See interim report from WGCRAb 2014.

PAPER OUTCOME

- For snow crab a draft manuscript entitled 'Dynamics of Snow Crab (*Chionoecetes opilio*) Movement and Migration Along the Newfoundland and Labrador and Eastern Barents Sea Continental Shelves' was presented in 2016. The manuscript had been submitted for primary publication prior to meeting. The manuscript was collaboratively developed by Canadian and Russian members of the working group.
- Haig J., Bakke Snorre., Bell M.C., Bloor I.S.M., Cohen M., Coleman M., Dignan S., Kaiser M.J., Pantin J.R., Roach M., Salomonsen H., Tully O. 2016. Reproductive traits and factors affecting the size at maturity of *Cancer pagurus* across Northern Europe. ICES Journal of Marine Science, doi:10.1093/icesjms/fsw081

METHODS

- Creation of a standard protocol for measuring size at maturity in *Cancer pagurus*.

ASSESSMENT

- For Atlantic Canada and Greenlandic snow crab. We have our own advisory processes.

ASSESSMENT METHODS/ FUTURE PLANS

- The WG decided to continue reviewing prospects for future assessment, advice including data availability, assessment methods and research on the biology of crab and lobster. The group agreed to make progress in evaluating assessment methods, sharing new knowledge of the species and working toward collaborating projects.

- It is a general agreement among the Group members that the annual meeting is of great value for each member, both to sum up the development in the different regional crab fisheries, and as a forum to discuss challenges in the management of the fisheries. WGCRAb is also a suitable arena for discussing particular issues on crab and lobster biology which is important since specialists working with the assessment on those species are mostly single scientists in this field at the different national institutions. Despite a limited number of attendants at the recent meetings, all members of the Group are enthusiastic to continue the work within the Group through annual meetings.
- AnnDorte Burmeister (Chair: 2014–2016) is stepping down.
Martial Laurans, France, was elected as new Chair for 2017–2019.
- The WGCRAb next meeting will be held in Brest, France, 7–9 November 2017.

Annex 2: WGCRAE Self-evaluation

- 1) Working Group name: **WGCRAE**
- 2) Year of appointment: **2014**
- 3) Current Chair: AnnDorte Burmeister (2014–2016)
- 4) Venues, dates and number of participants per meeting:
 - 2014: Tromsø, 22–24 April 2014 (11 participants)
 - 2015: Brest, 3–5 November 2015 (12 participants)
 - 2016: Aberdeen, 1–3 November 2017 (16 participants)

WG Self-Evaluation

- 5) If applicable, please indicate the research priorities (and sub priorities) of the Science Plan to which the WG make a significant contribution.
 - WGCRAE does not have any research priorities as such but is agreed upon modelling data in an effort to give advice on the various North Atlantic crab stocks
 - WGCRAE wish to use the data collected to perform population assessments (data-limited assessments).
 - The group contribute to the goal 2 of the science plan (“GOAL 2 - Understand the relationship between human activities and marine ecosystems, estimate pressures and impacts, and develop science-based, sustainable pathways”, by providing valuable information through discussion and dissemination of recent results.
- 6) In bullet form, highlight the main outcomes and achievements of the WG since their last evaluation. Outcomes including publications, advisory products, modelling outputs, methodological developments, etc. *
 - For most WGCRAE members, the species of interest in this WG are brown crab and European lobster. However also, work of other crab species such as spider crab, snow crab and king crab is also of interest. Through annual meetings it has been possible to report and discuss with international experts on issues regarding fisheries data, biology, assessment methods, climate change and ecosystem impact on the main crab and lobster species in the countries participating in the WG.
 - Irish representatives that have attended WGCRAE are due to attend a focus group meeting held by North Western Waters Advisory Council in late February/early March to inform the group in relation to stock areas that are defined around the North Western Waters area and in relation to data limited stocks and what can be put in place to improve data collection of these stocks.

- Presented work on methodologies being developed for harvest control rules using length-based indicators applied to crustaceans.
 - Presented the methodologies and results of the latest MSS stock assessments for brown crab and lobster using the latest available data.
 - Work by some members has begun to trial various models in an effort to get a handle on the status of the various North Atlantic Crab stocks.
 - Work presented on estimating size at maturity of brown crab in Scottish waters.
 - Presented work on using VMS to estimate effort in crab fisheries.
 - Move towards standardised protocol for maturity assessment of Brown Crab
 - Progress in ageing techniques of brown crab and lobster.
 - Progress on developing a standardised catch-profile protocol (science pots etc).
 - Paper: Haig, J. A., S. Bakke, M. C. Bell, I. S. M. Bloor, M. Cohen, M. Coleman, S. Dignan, M. J. Kaiser, J. R. Pantin, M. Roach, H. Salomonson and O. Tully (2016). "Reproductive traits and factors affecting the size at maturity of *Cancer pagurus* across Northern Europe." ICES Journal of Marine Science: Journal du Conseil. The mentioned paper was a result from a trans-national cooperation several members of the ICES WGCRAb group participated.
- 7) Has the WG contributed to Advisory needs? If so, please list when, to whom, and what was the essence of the advice.
- This Working Group does not produce any advice on the included species. However, it has been agreed that the WG will continue to discuss and evaluate assessment methodologies, the use of indicators and reference points for management.
- 8) Please list any specific outreach activities of the WG outside the ICES network (unless listed in question 6). For example, EC projects directly emanating from the WG discussions, representation of the WG in meetings of outside organizations, contributions to other agencies' activities.
- EFF funded research on brown crab maturity trial (Haig *et al.*, 2016).
- 9) Please indicate what difficulties, if any, have been encountered in achieving the workplan.

Future plans

- 10) Does the group think that a continuation of the WG beyond its current term is required? (If yes, please list the reasons)

- Yes. Specifically to apply Data Limited Methods being developed by WKLife to Crab stocks and to identify data requirements for a range of DLM approaches.
- Yes. Brown crab & lobster in particular are poorly understood in terms of stock boundaries and assessment methods. Scientific cooperation and communication in WG forum is essential going forward.
- Yes. Crab stocks represent important resources and further work in developing assessment methods/tools for these stocks is important.
- As few people are involved in crab work in the different national labs, WGCRAb serves an important function as a yearly meeting place for exchanging results and discussing new methods etc.

11) If you are not requesting an extension, does the group consider that a new WG is required to further develop the science previously addressed by the existing WG.

(If you answered YES to question 10 or 11, it is expected that a new Category 2 draft resolution will be submitted through the relevant SSG Chair or Secretariat.)

12) What additional expertise would improve the ability of the new (or in case of renewal, existing) WG to fulfil its ToR?

- If the WG is ever to move towards advisory work, numerical expertise will be required to evaluate stock assessment outcomes and methodologies.
- Membership should include ICES stock assessment scientists familiar with DLM (Data limited stock assessment methods)

13) Which conclusions/or knowledge acquired of the WG do you think should be used in the Advisory process, if not already used? (please be specific)

- Movement data with reference to stock assessment units.

Annex 3: WGCRA B draft MA terms of reference 2017–2019

The **Working Group on the Biology and Life History of Crabs** (WGCRA B), chaired by Martial Laurans*, France, will work on ToRs and generate deliverables as listed in the table below.

	MEETING DATES	VENUE	REPORTING DETAILS	COMMENTS (CHANGE IN CHAIR, ETC.)
Year 2017	7–9 November	Brest, France	Interim report by 15 December 2017 to SSGEPD	
Year 2018			Interim report by Date Month to SSGEPD	
Year 2019			Final report by Date Month to SCICOM	

ToR descriptors

ToR	DESCRIPTION	BACKGROUND	SCIENCE PLAN TOPICS ADDRESSED	DURATION	EXPECTED DELIVERABLES
a	Compile data on landings, discards, effort and catch rates (CPUE) and provide standardised CPUE, size frequency and research survey data for the important crab and lobster (<i>Homarus</i>) fisheries in the ICES area, and Atlantic Canada and Greenland.	The fisheries for crabs and lobster are socio-economically important and trans-national in Europe and Canada with the demise of fin fisheries in some regions.	10,13, 14, 25, 26, 30, 31	3 years	Landing, discard, effort and catch data on listed species, from each country. WG report chapter
b	Evaluate assessment of the status of crab and lobster (<i>Homarus</i>) stocks including use of indicators, empirical assessment, analytical assessment in relation to data sources and data quality, development and suitability of reference points for management.	Management of stocks in Europe is primarily by technical measures only and in most countries there are generally no management instruments to control fishing effort. Knowledge of the population dynamics of these species is still weak. These stocks may be at risk from over-fishing due to the lack of control of fishing effort, and hence an evaluation of the sustainability of these fisheries is necessary.	13, 14, 15,16,19	3 years	Report on evaluation of alternative assessment methods.
d	Review the impact of climate divers on important crab and lobster species within the ICES, Atlantic Canada and West Greenland, including increased ocean acidification;	WGCRA B will investigate the relative importance of fishing and environment on crab and lobster recruitment. Furthermore there is a growing concern in the WG about the consequences of future climate change for important crab species in our region. Observed increases in sea water temperatures have already entailed expanded	3, 4, 6	3 years	Highlight important issues to be basis for research on effect of climate changes on important crab stocks. WG report chapter (2019)

		distribution areas of some species in the northeast Atlantic. However, a rise in the seawater pH would probably be the most serious consequences of the climate change on crustaceans such as crabs. These issues will be dealt with by the WGCRAb in future.		
e	Review research and new knowledge on vital crab and lobster population biology parameters;	Several stock parameters are important for analytical assessments. Biological information is therefore required to provide standardised indices and for use in analytical assessments. Crab stock parameters may change due to size selective and single sex fisheries, through by-catch in other fisheries or through the impact of other seabed uses, such as gravel extraction. Since important crab stocks in Europe are managed without fishery independent data it may be an option to investigate any useful stock parameter indicators for assessment purposes.	3, 4, 19, 20, 21	Updated knowledge on crucial stock parameters for important crab stocks.

Summary of the Work Plan

Year 1	Annual standard outputs for a, b. Continue analysis for ToR d, e. Tentative plan for ToR c.
Year 2	Annual standard outputs for a, b. Continue analysis for ToR d, e. Complete evaluation of useful assessment methods to assess crab and lobster species in ICES areas. Complete request to ACOM and SCICOM (being both an assessment, advice and working group).
Year 3	Annual standard outputs for a, b. Combine analysis, research and report ToR d and e.

Supporting information

Priority	High. The fisheries for crabs and lobster are socio-economically important and trans-national in Europe and Canada with the demise of fin fisheries in some regions. Management of stocks in Europe is primarily by technical measures only and in most countries there are generally no management instruments to control fishing effort. Knowledge of the population dynamics of these species is still weak. These stocks may be at risk from over-fishing due to the lack of control on fishing effort, and hence an evaluation of the sustainability of these fisheries is necessary. The activity of the Group is therefore considered to be of high priority in particular if it's activity can move towards resource assessment without losing biological inputs.
Resource requirements	The research programmes which provide the main input to this group are already underway, and resources are already committed. The additional resource required to undertake additional activities in the framework of this group is negligible..

Participants	The Group is normally attended by some 10–15 members and guests.
Secretariat facilities	None.
Financial	No financial implications.
Linkages to ACOM and groups under ACOM	There are no obvious direct linkages today, but if the EG will produce stock assessments in future WGCRAb will have linkages to several EGs under ACOM.
Linkages to other committees or groups	The EG aims to be able to give advises on how to exploit important crab stocks in the ICES area and is therefore related to EGs such as WGCRAb and the ICES/NAFO NIPAG.
Linkages to other organizations
