# 2 Blue whiting (Micromesistius poutassou) in subareas 27.1-9, 12, and 14 (Northeast Atlantic) 

#### Abstract

Blue whiting (Micromesistius poutassou) is a small pelagic gadoid that is widely distributed in the eastern part of the North Atlantic. The highest concentrations are found along the edge of the continental shelf in areas west of the British Isles and on the Rockall Bank plateau, where it occurs in large schools at depths ranging between 300 and 600 meters, and is also present in almost all other management areas between the Barents Sea and the Strait of Gibraltar and west to the Irminger Sea. Blue whiting reaches maturity at $2-7$ years of age. Adults undertake long annual migrations between the feeding and spawning grounds. Most of the spawning takes place between March and April, along the shelf edge and banks west of the British Isles. Juveniles are abundant in many areas, with the main nursery area believed to be the Norwegian Sea. See the Stock Annex for further details on stock biology.

### 2.1 ICES advice in 2020

ICES notes fishing mortality $(\mathrm{F})$ is estimated to be above $\mathrm{F}_{\text {MSY }}$ since 2014. Spawning-stock biomass (SSB) has been decreasing since 2018; however, it is estimated to remain above MSY Btrigger. Recruitment (R) from 2017 to 2020 is estimated to be low, following a three-year period of high recruitment. ICES advises that when the long-term management strategy agreed by the European Union, the Faroe Islands, Iceland, and Norway is applied, catches in 2021 should be no more than 929292 tonnes.

### 2.2 The fishery in 2020

The total catch in 2020 was 1.495 million tonnes. The main fisheries on blue whiting were targeting spawning and post-spawning fish (Figures 2.2.1 and 2.2.2). Most of the catches (85.5\%) were taken in the first two quarters of the year and the largest part of this was taken along the slopes of the Western European shelf, in the Rockall Trough and in the deep trenches around the Faroes. Smaller quantities were taken in the southern part of the Norwegian Sea, in the Norwegian Trench and along the coast of Spain and Portugal. The fishery in the second half of the year was mainly east of the Faroes and in the central Norwegian Sea, with smaller amounts in the Norwegian Trench and along the coast of Portugal and Spain.

The multinational fleet targeting blue whiting in 2020 consisted of several types of vessels from 17 countries. The bulk of the catch is caught with large pelagic trawlers, some with capacity to process or freeze on board. The remainder is caught by RSW vessels.

### 2.3 Input to the assessment

At the Inter-Benchmark Protocol on Blue Whiting, IBPBLW (ICES, 2016a), it was decided to use preliminary within year, quarter 1 and quarter 2 , catch-at-age data in the assessment to get additional information to the within year IBWSS survey estimates. In recent years, between 85-90\% of the annual catches of the age 3+ fish have been taken in the first half of the year, which makes it reasonable to estimate the total annual catch-at-age from reported first semester (Q1 \& Q2) data and expected total catches for the remainder of the year. The catch data sections in this report contain a comprehensive description of the 2020 data as reported to ICES and a brief description of the 2021 preliminary catch data.

### 2.3.1 Officially reported catch data

Official catches in 2020 were estimated as 1495248 tonnes based on data provided by WGWIDE members (Table 2.3.1.1). Data provided as catch by rectangle represented $99 \%$ of the total WG catch in 2020.

In 2020, the majority of catches were caught on the spawning grounds with largest contribution from ICES area 27.7.c, 27.7.k, and 27.5.b, 27.6.a respectively (Figure 2.3.1.1; Tables 2.3.1.2, 2.3.1.3), and caught respectively in quarter 1 and quarter 2 (Figure 2.3.1.6). In the first two quarters, catches are taken over a broad area, with the highest catches respectively in 27.5.b, 27.6.a, 27.7.c and 27.7.k while later in the year catches are mainly taken further north in area 27.2.a and in the North Sea (27.4.a) (Figures 2.3.1.6 and 2.3.1.7 and Table 2.3.1.3).The spatial and temporal distribution of catches in 2020 are similar to previous years (Figures 2.3.1.2, 2.3.1.3, 2.3.1.4; Table 2.3.1.4). The majority of the blue whiting catch was caught by five nations - Norway, Faroe Islands, Iceland, and Russia, respectively (Figure 2.3.1.5).

Discards of blue whiting are small. Most of the blue whiting caught in directed fisheries are used for reduction to fish meal and fish oil. However, some discarding occurs in the fisheries for human consumption and as bycatch in fisheries targeting other species.

Reports on discarding from fisheries which catch blue whiting were available from the Netherlands for the years 2002-2007 and 2012-2014. A study carried out to examine discarding in the Dutch fleet found that blue whiting made a minor contribution to the total pelagic discards when compared with the main species mackerel, horse mackerel and herring.
The blue whiting discards data provided by Portuguese vessels operating with bottom otter trawl within the Portuguese portions of ICES Division 27.9.a are available since 2004. The discards data are from two fisheries: the crustacean fishery and the demersal fishery. The blue whiting estimates of discards in the crustacean fishery for the period of 2004-2011 ranged between $23 \%$ and $40 \%$ (in weight). For the same period the frequency of occurrence in the demersal fishery was around zero for the most of the years, in the years where it was significant $(2004,2006,2010)$ ranged between $43 \%$ and $38 \%$ (in weight). In 2020, discards were $28 \%$ of the total catches for blue whiting along the Portuguese coast (Table 2.3.1.5). The total catch from Portugal is less than a half percentage of the total international catches.

Information on discards was available for Spanish fleets since 2006. Blue whiting is a bycatch in several bottom-trawl mixed fisheries. The estimates of discards in these mixed fisheries in 2006 ranged between $23 \%$ and $99 \%$ (in weight) as most of the catch is discarded and only the catch of the last day may be retained for marketing fresh. The catch rates of blue whiting in these fisheries are however low. In the directed fishery for blue whiting for human consumption with pair trawls, discards were estimated to be $4 \%$ (in weight) in 2020 (Table 2.3.1.5). Spanish catches are around $2 \%$ of the international catches.

In general, discards are assumed to be small in the blue whiting directed fishery. Discard data are provided by Denmark, Ireland, Portugal, Spain, Sweden, UK (England and Wales) and UK (Scotland) to the working group. The discards constituted $0.19 \%$ of the total catches, 2828 tonnes. BMS landings were reported by UK (England and Wales), although no minimum conservation reference size is defined on blue whiting, those landings are related to fish that have not been sold at market but was landed, for example damaged fish, and it correspond to 8 tonnes in 2020. The largest fishing nations, Norway, Faroe Islands, Russia and Iceland do not provide discards information.

The total estimated catches (tonnes) inside and outside the NEAFC regulatory area by country were reported on Table 2.3.1.6. The catches inside the NEAFC RA represent $16 \%$ of the total catches of blue whiting in 2020.

### 2.3.1.1 Sampling intensity

In $2020,81 \%$ of catches were covered by the sampling program. In 2020, 672 length samples, 580 age samples, were collected from the fisheries, and 89110 fish were measured and 16641 were aged. Sampling intensity for blue whiting with detailed information on catch, proportion of catch covered by sampling program, the number of samples, number of fish measured, and number of fish aged per year from 2000 to 2020 is given in Table 2.3.1.1.1. Sampling intensity per country, quarter and ICES division for 2020 is listed in Tables 2.3.1.1.2, 2.3.1.1.3 and 2.3.1.1.4. The most intensive sampling, considering the age samples and the number of aged fish, took place in areas 27.2.a, 27.5.b, 27.6.b, 27.7.b, 27.7.c, 27.7.k, 27.8.c and 27.9.a. No sampling was carried out by Greenland, Lithuania, Poland, Sweden and the UK (Northern Ireland) which combined represent $5 \%$ of the total catches. The sampled and estimated catch-at-age data are shown on Figure 2.3.1.1.1.

Sampling intensity for age and weight of blue whiting are made in proportion to landings according to CR 1639/2001 and apply to EU member states. The Fisheries Regulation 1639/2001, requires EU Member States to take a minimum of one sample for every 1000 tonnes landed in their country. Various national sampling programs are in force.

### 2.3.1.2 Age compositions

As an example of an age-length key from sampled catches in 2020, data from ICES area 27.6.a is presented by quarter and country (Figure 2.3.1.2.1). The mean length (mm) by ages reveals that age classifications do present some differences between countries. The difference in mean length-at-age increases in older ages, higher than age 6 .

The ICES InterCatch program was used to calculate the total international catch-at-age, and to document how it was done.

### 2.3.2 Preliminary 2021 catch data (Quarters 1 and 2)

The preliminary catches for 2021 as reported by the WGWIDE members are presented in Table 2.3.2.1.

The spatial distribution of these 2021 preliminary catches is similar to the distribution in 2020 with majority of catches taken in division 27.6.a, 27.5.b, 27.7.c and 27.7.k (Figure 2.3.2.1 and Table 2.3.2.2).

Sampling intensity for blue whiting from the preliminary catches by area with detailed information on the number of samples, number of fish measured, and number of fish aged is presented in Table 2.3.2.2.

WGWIDE estimated the expected total catch for 2021 from the sum of declared national quotas, corrected for expected national uptake and transfer of these quotas (Table 2.3.2.3).

For the period 2016 to 2020, preliminary and final catch estimates are similar with maximum deviation in 2020 when the final catch was $21 \%$ higher than the preliminary catch (Table 2.3.2.4). Age compositions (Figure 2.3.2.2) are also similar between preliminary and final catch data. There is no clear pattern in the deviations; it is both the catch at age for young and older fish that change between preliminary and final data.

The estimation of catch at age and mean weight at age followed the method described in the Stock Annex.

### 2.3.3 Catch-at-age

Catch-at-age numbers from 1981 to 2021 are presented in Table 2.3.3.1 and catch proportions at age shown in Figure 2.3.3.1. Strong year classes that dominated the catches can be clearly seen in the early 1980s, 1990 and the late 1990s. More recently, the propagation of the large 2014 year class is also evident.

Catch curves for the international catch-at-age dataset (Figure 2.3.3.2), indicate a consistent decline in catch number by cohort in years with rather high landings (and probably similar high effort). The catch curves for year classes 2010-2014 show a consistent decline in the stock numbers with an estimated total mortality $(\mathrm{Z}=\mathrm{F}+\mathrm{M})$ around $0.6-0.7$ for the ages fully recruited ages to the fisheries. With an assumed natural mortality $(\mathrm{M}=0.2)$, the assessment F around $0.4-0.5$ fits well to the Z values estimated from the catch curves.

### 2.3.4 Weight at age

Table 2.3.4.1 and Figure 2.3.4.1 show the mean weight-at-age for the total catch during 1981-2021 used in the stock assessment. Mean weight at ages 3-9 has generally decreased in the period 20102018, followed by an increase in the most recent years, for the most abundant ages in the catches.

The weight-at-age for the stock is assumed the same as the weight-at-age for the catch.

### 2.3.5 Maturity and natural mortality

Blue whiting natural mortality and proportion of maturation-at-age are shown in Table 2.3.5.1. See the Stock Annex for further details.

### 2.3.6 Information from the fishing industry

No new information available.

### 2.3.7 Fisheries independent data

Data from the International Blue Whiting spawning stock survey are used by the stock assessment model, while recruitment indices from several other surveys are used to qualitatively adjust the most recent recruitment estimate by the assessment model and to guide the recruitments used in the forecast.

### 2.3.7.1 International Blue Whiting spawning stock survey

The Stock Annex gives an overview of the surveys available for the blue whiting. The International Blue Whiting Spawning Stock Survey (IBWSS) is the only survey used as input to the assessment model.

The full time series of IBWSS was recalculated in summer 2020, using the same software (StoX; Johnsen et al., 2019) and method as previously applied. The values are presented in Table 2.3.7.1.1 and Figure 2.3.7.1.1A

The survey time-series (2004-2021) show variable internal consistency ranging from 0.26 to 0.86 (Figure 2.3.7.1.1B) The overall internal consistency plot for age-disaggregated year classes was slightly reduced compared to last year. There is a high internal consistency for the younger ages (1-5 years) and older ages (7-9 years) with correlation between 0.70 and 0.86 , but poor $(0.02<\mathrm{r}<$ 0.03 ) between ages 5 to 8 . This may indicate age readings problems for this group of ages.

The distribution of acoustic backscattering densities for blue whiting for the period 2018-2021 is shown in Figure 2.3.7.1.2. The abundance estimate of blue whiting for IBWSS are presented in Table 2.3.7.1.1.

Length and age distributions for the period 2017 to 2021 are given in Figure 2.3.7.1.3.
Survey indices, (ages 1-8 years 2004-2021) as applied in the stock assessment are shown in Table 2.3.7.1.1.

### 2.3.7.2 Other surveys

The Stock Annex provides information and time-series from surveys covering parts of the stock area. A brief survey description and survey results are provided below.
The International ecosystem survey in the Nordic Seas (IESNS) in May which is aimed at observing the pelagic ecosystem with particular focus on Norwegian spring-spawning herring and blue whiting (mainly immature fish) in the Norwegian Sea (Table 2.3.7.2.1).
Norwegian bottom-trawl survey in the Barents Sea (BS-NoRu-Q1(Btr)) in February-March where blue whiting are regularly caught as a bycatch species. This survey gives the first reliable indication of year class strength of blue whiting. The 1-group in this survey is defined as less than 19 cm (Table 2.3.7.2.2).

Icelandic bottom-trawl surveys on the shelf and slope area around Iceland. Blue whiting is caught as bycatch species and 1-group is defined as less than 22 cm in March (Table 2.3.7.2.3).

Faroese bottom-trawl survey on the Faroe plateau in spring where blue whiting is caught as bycatch species. The 1-group in this survey is defined as equal or less than 23 cm in March (Table 2.3.7.2.4).

The International Survey in Nordic Seas and adjacent waters in July-August (IESSNS). Blue whiting are from 2016 included as a main target species in this survey and methods are changed to sample blue whiting. This was a recommendation from WGWIDE 2015 to try to have one more time-series for blue whiting. Data for the survey are not used yet, due to the short time series.

### 2.4 Stock assessment

The IBWSS survey is the only survey used by the SAM assessment. The survey was cancelled in 2020 due to the COVID-19 pandemic, but conducted as planned in 2021.

The presented assessment in this report follows the recommendations from the Inter-Benchmark Protocol of Blue (ICES, 2016a) to use the SAM model. The configuration of the SAM model was kept unchanged in this year's assessment.

The time period for estimating recruitment for forecast, was changed from the full time series (minus terminal year) to the period since 1996 (minus terminal year).

### 2.4.1 2021 stock assessment

For a model as SAM, Berg and Nielsen (2016) pointed out that the so-called "One Step Ahead" (OSA) residuals should be used for diagnostic purposes. The OSA residuals (Figure 2.4.1.1) show a quite random distribution of residuals. There might be an indication of "years effect" (too low index) for the IBWSS 2015 observations which has also be seen in previous assessment.

The estimated parameters from the SAM model from this year's assessment and from previous years (retrospective analysis) are shown in Table 2.4.1.1. There are no abrupt changes in the estimated parameters over the time-series presented. The lowest observation noises, and thereby
the largest weight in the assessment model, have in all years been from catches at ages 3-8, which constitute the largest proportion of the catch.

The process error residuals ("Joint sample residuals") (Figure 2.4.1.2) are reasonable randomly distributed. Process noise SAM is implemented as a "process mortality, Z"; these deviations in mortalities are shown in Figure 2.4.1.3. The deviations in mortality (plus or minus mortality) seems fairly randomly distributed without very pronounced clusters as also seen in Figure 2.4.1.2).

The correlation matrix between ages for the catches and survey indices (Figure 2.4.1.4) shows a modest observation correlation for the younger ages and a stronger correlation for the older ages. This difference is more distinct for catches, probably because it includes older ages (1-10+) than the survey data (ages 1-8).

Figure 2.4.1.5 presents exploitation pattern for the whole time-series. There are no abrupt changes in the exploitation pattern from 2010 to 2021, even though the landings in 2011 were just $19 \%$ of the landings in 2010, which might have given a different fishing practice. The plateau in selection at age 6 and older seen since mid-2000s seems more realistic than the more linear selection estimated for the beginning of the time series. The estimated rather stable exploitation pattern might be influenced by the use of correlated random walks for $F$ at age with a high estimated correlation coefficient ( $\mathrm{Rho}=0.93$, Table 2.4.1.1).

The retrospective analysis (Figure 2.4.1.6) shows a stable assessment for the last 5 years, previous years within $95 \%$ CI for the current assessment. Mohn's rho by year and as the average value over the last five years are presented in (Table 2.4.1.2). Even though the annual values might be high for recruitment (reflecting large changes from one year to the next) the average Mohn's rho is low for both recruitment, F and SSB, indicating no bias.

Stock summary results with added $95 \%$ confidence limits (Figure 2.4.1.7 and Table 2.4.1.5) show a decrease in fishing mortality in the period 2004-2011, followed by a steep increase in F up to 2015 after which F has fluctuated around 0.45 . Recruitment was historically high in 2015, followed by a lower recruitment in 2016 and much lower recruitments in 2017-2019. The recruitment in most recent years is estimated higher. SSB has increased in the period 2010-2018, followed by a large reduction.

Comparison of the assessment made in 2020 and 2021 (Figure 2.4.1.8) shows that the uncertainties on F and SSB in the terminal year are higher in the assessment from last year, where the IBWSS survey was cancelled due to Covid-19. The uncertainties on the recruitment estimates in the terminal seem however slightly higher this year. Last year, there were only one (the catch) observation for age 1 in the terminal year, while both catch and survey observations are present in 2021. For age 1, the lowest observation variance (Table 2.4.1.1) is estimated for catch observation, so the 2020 situation with only one age 1 observation, seems (statistically) to produce a more certain recruitment estimate in the terminal year.

### 2.4.2 Alternative model runs

The assessment XSA and TISVPA models were run for a better screening of potential errors in input and for comparison with the SAM results. The three models gave a similar result (Figure 2.4.2.1), however with some differences in F in the terminal years. even though the absolute values differ between models. XSA estimates the highest F, TISVPA the lowest F and SAM estimates a value in between.

The working document WD11 "Blue whiting, an alternative assessment including more surveys" (Hølleland et al., 2021 ) was presented to the WGWIDE. The assessment is a SAM assessment, and made use of two (IESNS and IESSNS) additional survey data for blue whiting. The time
series for IESSNS is still short (6 years). The alternative assessment gave similar results for SSB and F as estimated by the presently used SAM (Figure 2.4.3.2). The estimated recruitment in 2021 was however larger in the alternative assessment, due to high abundance of age 1 in 2021 in both additional surveys.

### 2.5 Final assessment

Following the recommendations from Inter-Benchmark Protocol on Blue Whiting (ICES, 2016a) the SAM model is used for the final assessment. The model settings can be found in the Stock Annex.

Input data are catch numbers-at-age (Table 2.3.3.1), mean weight-at-age in the stock and in the catch (Table 2.3.4.1) and natural mortality and proportion mature in Table 2.3.5.1. Applied survey data are presented in Table 2.3.7.1.1.

The model was run for the period 1981-2021, with catch data up to 2020 and preliminary catch data for the first semester (Q1 and Q2) of 2021 raised to expected annual catches, and survey data from March-April, 2004-2021. SSB 1 ${ }^{\text {st }}$ January in 2022 is estimated from survivors and estimated recruits (for 2021 estimated outside the model, see short-term forecast section). $11 \%$ of age group 1 is assumed mature, thus recruitment influences the size of SSB. The key results are presented in Tables 2.4.1.3-2.4.1.4 and summarized in Table 2.4.1.5 and Figure 2.4.1.7. Residuals of the model fit are shown in Figures 2.4.1.1 and 2.4.1.2.

### 2.6 State of the Stock

Fishing pressure (2021) on the stock is above $\mathrm{F}_{\mathrm{mSy}}$ and between $\mathrm{F}_{\mathrm{pa}}$ and $\mathrm{F}_{\text {lim }}$; spawning-stock size (2022) is above MSY $B_{\text {trigger, }} B_{p a}$ and $B_{\text {lim }}$.

F has increased from a historic low at 0.052 in 2011 to around 0.45 since 2014. F has been above Fmsy and Fpa 0.32) since 2015. SSB increased from 2010 ( 2.69 million tonnes) to 2017 ( 6.06 million tonnes), followed by a decline to 3.40 million tonnes in 2022.

Recruitment (age 1 fish) was high in 2014-2016 followed by recruitments in the low end of the historical recruitments in the years 2017-2019. This is followed by a moderate increase in recruitment in 2020 and 2021. The lower recruitment in combination with a high F in recent years have resulted in a decline in SSB.

### 2.7 Biological reference points

In spring of 2016, the Inter-Benchmark Protocol on Blue Whiting (IBPBLW) (ICES, 2016a) delegated the task of re-evaluating biological reference points of the stock to the ICES Workshop on Blue Whiting Long Term Management Strategy Evaluation (WKBWMSE) (ICES 2016b). During the WGWIDE meeting 2017, WKBWMSE concluded to keep $\mathrm{B}_{\mathrm{lim}}$ and $\mathrm{B}_{\mathrm{pa}}$ unchanged but revised $\mathrm{F}_{\mathrm{lim}}, \mathrm{F}_{\mathrm{pa}}$, and $\mathrm{F}_{\mathrm{ms}}$.

ICES made in 2021 the decision to use $\mathrm{F}_{\mathrm{p} 05}$ as the value for $\mathrm{F}_{\mathrm{pa}}$. $\mathrm{F}_{\mathrm{p} 05}$ was estimated by WKBWMSE (ICES 2016b), where it was concluded that the EQSIM simulations showed that $\mathrm{Fp}_{0.05}(0.32)$ is less than the $\mathrm{F}_{\text {MSY }}$ in the constant F simulations, so $\mathrm{F}_{\text {MSY }}$ was set to this lower value.

The table below summarises the currently used reference points.

| Framework | Reference point | Value | Technical basis | Source |
| :---: | :---: | :---: | :---: | :---: |
| MSY approach | MSY $\mathrm{B}_{\text {trigger }}$ | $2.25 \text { mil- }$ <br> lion t | $\mathrm{B}_{\mathrm{pa}}$ | ICES (2013a, 2013b, 2016b) |
|  | $\mathrm{F}_{\text {MSY }}$ | 0.32 | Stochastic simulations with segmented regression stock-recruitment relationship | ICES (2016b) |
| Precautionary approach | $\mathrm{Blim}^{\text {l }}$ | $\begin{aligned} & 1.50 \text { mil- } \\ & \text { lion } t \end{aligned}$ | Approximately $\mathrm{B}_{\text {loss }}$ | ICES (2013a, 2013b, 2016b) |
|  | $\mathrm{B}_{\mathrm{pa}}$ | $2.25 \text { mil- }$ <br> lion t | $\mathrm{B}_{\mathrm{lim}} \exp (1.645 \times \sigma)$, with $\sigma=0.246$ | ICES (2013a, 2013b, 2016b) |
|  | $F_{\text {lim }}$ | 0.88 | Equilibrium scenarios with stochastic recruitment: F value corresponding to $50 \%$ probability of (SSB< $\mathrm{B}_{\text {lim }}$ ) | ICES (2016b) |
|  | $\mathrm{F}_{\mathrm{pa}}$ | 0.32 | Fp05; the F that leads to SSB $\geq$ Blim with $95 \%$ probability | ICES (2016b) and WGWIDE 2021 |

### 2.8 Short-term forecast

### 2.8.1 Recruitment estimates

The benchmark WKPELA in February 2012 concluded that the available survey indices should be used in a qualitative way to estimate recruitment, rather than using them in a strict quantitative model framework. The WGWIDE has followed this recommendation and investigated several survey time-series indices with the potential to give quantitative or semi-quantitative information of blue whiting recruitment. The investigated survey series were standardized by dividing with their mean and are shown in Figure 2.8.1.1.

The International Ecosystem Survey in the Nordic Seas (IESNS) only partially covers the known distribution of recruitment from this stock. The 1-group (2020 year class) and the 2 -group (2019 year class) indices from the survey in 2021 were above the median and below the median of the historical range, respectively.

The 1-group (2020 year class) and the 2-group (2019 year class) indices from The International Blue Whiting Spawning Stock Survey (IBWSS) was above the median in the time series (Table 2.3.7.1.1).

The Norwegian bottom-trawl survey in the Barents Sea (BS-NoRu-Q1(Btr)) in February-March 2021, showed that 1-group blue whiting was the third highest in the time series (Table 2.3.7.2.2). This index should be used as a presence/absence index, in the way that when blue whiting is present in the Barents Sea, this is usually a sign of a strong year class, as all known strong year classes have been strong also in the Barents Sea.

The 1-group estimate in 2021 (2020 year class) from the Icelandic bottom-trawl survey showed an increase compared to 2020 and was the highest in the time-series.

The 1-group estimate in 2021 ( 2020 year class) from the Faroese Plateau spring bottom-trawl survey showed an increase compared to 2020 and was below the median in the time-series.

In conclusion, the indices from available survey time-series indicate that the 2019 year class is above the median it corresponds to the SAM assessment results. The 2020 year classes estimated from surveys are also above the median, which also is the result of the SAM assessment. It was therefore decided not to change the SAM estimate of the 2019 and 2020 year classes.

No information is available for the 2022 and 2023 year classes and the geometric mean of the time-series from 1996-2020) was used for these year classes ( 20.98 billion at age 1 in 2022) (Table 2.8.1.1). WGWIDE decided to change from using the geometric mean of the full time-series (1981-2020) to use a shorter time-series for the calculations. The motivation for this change was to use a more recent period, which is assumed to better reflect the environmental changes and more variable recruitment in general since 1996. The reasons to shorten the time-series were twofold. Firstly, prior to 1995 only one time-series, the Barents Sea demersal trawl index, was available as a proxy for blue whiting recruitment. After 1995 several indices became available, beginning with the Faroese and Icelandic spring demersal surveys and later other proxies were included (Figure 2.8.1.1). Secondly, hydrographic time series in the northeast North Atlantic and Nordic Seas show that the freshening trend of the 1960s-1990s completely reversed in the upper ocean in the mid-1990s (Holliday et al., 2008). Since the weakening of the subpolar gyre in the mid-1990s temperature and salinity have rapidly increased in the Atlantic inflow to the Rockall/Hatton Plateau region, apparently leading to changes in the recruitment levels of blue whiting in the following decades (Hátún et al., 2009b, Payne et al., 2012). Recent hydrographic observations indicate again a freshening occurred in the area after 2015 (González-Pola et al., 2020).

### 2.8.2 Short-term forecast

As decided at WGWIDE 2014, a deterministic version of the SAM forecast was applied. Details about specific implementation can be found in the Stock Annex.

### 2.8.2.1 Input

Table 2.8.2.1.1 lists the input data for the short-term predictions. Mean weight at age in the stock and mean weight in the catch are the same, and are calculated as three year averages (2019 2021) in accordance with the 2019 updated Stock Annex. Selection (exploitation pattern) is based on F in the most recent year. The proportion mature for this stock is assumed constant over the years and values are copied from the assessment input.

Recruitment (age 1) in 2020 and 2021 are assumed as estimated by the SAM model, as additional survey information was not conflicting this result. Recruitment in 2022 and 2023 are assumed as the long-term average from the period with both high and low recruitments (geometric mean of the time-series since 1996, minus the terminal year, 1996-2020).

As the assessment uses preliminary catches for 2021 an estimate of stock size exist for the $1^{\text {st }}$ of January 2022. The normal use of an "intermediate year" calculation is not relevant in this case. F in the "intermediate year" (2021) is as calculated by the assessment model. Catches in 2021 is the (model input) preliminary catches. Intermediate year assumptions are summarised in Table 2.8.2.1.2.

### 2.8.2.2 Output

A range of predicted catch and SSB options from the deterministic short-term forecast used for advice are presented in Table 2.8.2.2.1.

Following the ICES MSY framework or the target $F$ from the LTMS implies fishing mortality to be at $\mathrm{F}_{\mathrm{MSY}}=0.32$ which will give a TAC in 2022 at 752736 tonnes. This corresponds to a $19.0 \%$ reduction compared to the ICES advice last year, and $39.4 \%$ reduction compared to the preliminary estimate of catches in 2021.

The LTMS specifies a TAC constraint at $+25 /-20 \%$. With at maximum decrease at $19 \%$ in catches in relation to the ICES advice last year (LTMS advice), the TAC constraint is not applied.

SSB in 2023 is predicted to increase by $19.1 \%$ to 4052163 tonnes, if the advised catches are taken. The higher recruitment estimated for 2020 and 2021 contributes to this increase in SSB.

### 2.9 Comparison with previous assessment and forecast

Comparison of the final assessment results from the last 5 years shows a consistent assessment (Figure 2.9.1). Historic fishing mortalities and recruitments are estimated higher this year, but the differences between this year's and last year's assessment results are small.

### 2.10 Quality considerations

Based on the confidence interval produced by the assessment model SAM there is a moderate to high uncertainty of the absolute estimate of F and SSB and the recruiting year classes (Figure 2.4.1.7). The retrospective analysis (Figure 2.4.1.6), the comparison of SSB and F estimated by three different assessment programs TISVPA, XSA and SAM (Figure 2.4.3.1) and the comparison of the 2017-2021 assessments (Figure 2.9.1) suggest a consistent assessment.

There are several sources of uncertainty: age reading, stock identity, and survey indices. As there is only one survey (IBWSS) that covers the spawning stock, the quality of the survey influences the assessment result considerably. The Inter-Benchmark Protocol on Blue Whiting (IBPBLW 2016) introduced a configuration of the SAM model that includes the use of estimated correlation for catch and survey observations. This handles the "year effects" in the survey observation in a better way than assuming an uncorrelated variance structure as usually applied in assessment models. However, a biased survey indices will still give a biased stock estimate with the new SAM configuration. The estimated correlation for catch at age observations might correspond to the age reading discrepancy as also estimated from inter-calibration exercise.

Utilization of preliminary catch data provides the assessment with information for the most recent year in addition to the survey information. This should give a less biased assessment, as potential biased survey data in the final year are supplemented by additional catch data.

Exploratory assessments (XSA, TISVPA) using the same data as the default assessment gave similar results as the default run. Another SAM assessments with data from two additional surveys (IESNS and IESSNS) included, showed a higher recruitment in the terminal year, and estimates similar $F$ and SSB.

The assessment uses data from one survey only, the International Blue Whiting Spawning Stock Survey, which was cancelled in 2020 due to the COVID-19 disruption, but continued in 2021. The lack of 2020 survey data seems not to increase the uncertainties of the assessment results this year, and the assessment results are consistent with the results from previous years.

### 2.11 Management considerations

The assessment estimates low 2016-2018 year classes and slightly higher 2019 and 2020 year classes. The large year 2014 and 2015 year classes have been reduced considerably through fishing and natural mortality and the will not contribute much to the catches in the coming years. The forecast predicts a 10-20\% increase in SSB (compared to SSB in 2022) depending on the F in 2022. This increase is dependent on the year class strength of the 2019 and 2020 year classes, whereas the size of the 2021 and 2022 have a limited effect for SSB in 2023.

### 2.12 Ecosystem considerations

Blue whiting is one of the most abundant pelagic and mesopelagic fish stocks in the Northeast Atlantic, SSB estimated from 1.4-6.9 million ton during the period from 1981 to 2020 (ICES, 2020). The stock is widely distributed and highly migratory. It's distribution range is approximately from latitude $30^{\circ} \mathrm{N}$ to $80^{\circ} \mathrm{N}$ and from the coast of Europe to Greenland, into Barents Sea and the Mediterranean Sea (Trenkel et al., 2014). Spawning is in the spring and mostly occurs on the shelf and banks west of Ireland and Scotland and major summer feeding area is in the Norwegian Sea. Blue whiting is most frequently observed at $100-600 \mathrm{~m}$ depth (Heino and Godo, 2002). Their most important prey is respectively euphausiids, amphipods and copepods (Pinnegar et al., 2015, Bachiller et al., 2016) and they are prey for piscivorous fish (Dolgov et al., 2010) and cetaceans (Hátún et al., 2009a). Large stock size suggests blue whiting is an important species in the pelagic and mesopelagic ecosystem of the NE Atlantic and it's best documented ecosystem interactions are listed below:
(a) Stock productivity - recruitment: blue whiting population dynamic is driven by large annual variability in recruitment (at age 1 in the assessment model) which is not linked to spawning stock size (ICES, 2020). Changes in recruitment have been correlated to changes in the North Atlantic subpolar gyre between strong and weak states (Hátún et al., 2009a,b). Two hypotheses have been suggested to explain a mechanical relationship between low gyre index and high recruitment (Payne et al., 2012). One suggests changes in marine climate where weak gyre results in increased flow of warm subtropical waters and increased abundance of important prey for juvenile blue whiting on their nursing grounds west of Ireland and Scotland. The other suggests increasing predation of mackerel on blue whiting larvae during years of weak index, but neither has been proven right (Payne et al., 2012). Future benchmarks should explore options to include the subpolar gyre index in the assessment model forecast for recruitment.
(b) Changes in distribution: blue whiting spawning distribution varies between years. It has been linked to the North Atlantic subpolar gyre as a strong gyre, cold and fresh water masses on the Rockall Plateau, shrinks the spawning area compared to a weak gyre, increasing saline and warm waters at Rockall, which expands the spawning area northward and westward into Rockall Plateau (Hátún et al., 2009a,b; Miesner and Payne, 2018). Salinity appears specifically to impact spawning location of blue whiting (Miesner and Payne, 2018). Future benchmarks should explore options to include information on spawning ground salinity in the assessment model forecast for recruitment.
(c) It is disputed if there are one or two blue whiting populations in the Northeast Atlantic (Keating et al., 2014; Pointin and Payne, 2014; ICES, 2016c; Mahé et al., 2016). Currently blue whiting is considered a single population for management purpose. Future benchmarks should explore the impact of single population assessment versus an assessment for two populations.
(d) Trophic interactions in the Norwegian Sea: it appears to be limited prey competition between blue whiting and the two other abundant pelagic species, Norwegian spring-spawning herring and Atlantic mackerel, as studies show limited dietary overlap between blue whiting and the two other species (Bachiller et al., 2016; Pinnegar et al., 2015). Limited prey competitions between blue whiting and mackerel can be explained by limited geographical overlap, mackerel mostly feed in the surface layer and blue whiting deeper in the water column (Utne et al., 2012). Where distribution of blue whiting and herring overlap (Utne et al., 2012) they appear to feed on different species, herring mainly feed on copepods and blue whiting mainly on euphausiids and amphipods, although juvenile blue whiting feed on copepods (Bachiller et al., 2016; Pinnegar et al., 2015). Given the current knowledge, future benchmarks do not need to consider prey competition between blue whiting and herring/mackerel, and therefore do not need to consider adding mackerel and NSS herring stock size to the blue whiting stock assessment model.

An extensive overview of ecosystem considerations relevant for blue whiting can be found in the Stock Annex.

### 2.13 Regulations and their effects

There is a long-term management strategy agreed by the European Union, the Faroe Islands, Iceland and Norway. However there is no agreement between the Coastal States, i.e. EU, Norway, Iceland and the Faroe Island on the share of the blue whiting TAC. The catch advice does not take into account consistent deviations from the long-term management strategy as evident from the sum of unilateral quotas since 2018. During the evaluation of the management strategy (ICES, 2016b), the implementation error in the form of a consistent overshoot of the TAC was not included. Therefore, the current implementation of the long-term management strategy may no longer be precautionary. See section 1.8 for a comparison of historic advice, TAC and catch.

WGWIDE estimates the total expected catch for 2021 to be 1242727 tonnes, whereas ICES advised that when the long-term management strategy agreed by the European Union, the Faroe Islands, Iceland, and Norway is applied, catches in 2021 should be no more than 929292 tonnes. This advice was followed by the Coastal States by setting a TAC at the ICES advice, however there was no agreement on the split of TAC between nations.

### 2.13.1 Management plans and evaluations

A response to NEAFC request to ICES to evaluate a long-term management strategy for the fisheries on the blue whiting ICES WKBWMSE was established in the fall of 2015. The ICES Advice September 2016, "NEAFC request to ICES to evaluate a long-term management strategy for the fisheries on the blue whiting (Micromesistius poutassou) stock" concluded that:

- That the harvest control rule (HCR) proposed for the Long-Term Management Strategy (LTMS) for blue whiting, as described in the request, is precautionary given the ICES estimates of Blim ( 1.5 million $t$ ), Bpa ( 2.25 million $t$ ), and $\operatorname{Fmsy}$ ( 0.32 ).
- The HCR was found to be precautionary both with and without the $20 \%$ TAC change limits above Bpa. However, the $20 \%$ TAC change limits can lead to the TAC being lowered significantly if the stock is estimated to be below Bpa, while also limiting how quickly the TAC can increase once the stock is estimated to have recovered above Bpa.
- The evaluation found that including a $10 \%$ interannual quota flexibility ('banking and borrowing') in the LTMS had an insignificant effect on the performance of the HCR.

The management strategy evaluation did not take into account consistent deviations from the long-term management strategy as evident from the sum of unilateral quotas in recent years. During the evaluation of the management strategy (ICES, 2016b), the implementation error in the form of a consistent overshoot of the TAC was not included. Therefore, the current implementation of the long-term management strategy may no longer be precautionary.

### 2.14 Recommendations

The WGWIDE expert group analysed the mean length at age by area and by quarter of the data submitted from the different institutes/member states and differences have been identified in the data from the different areas. Although, is expected that on the next year data, those differences should be almost neglected, because an age reading workshop just took place in 2021 (WKARBLUE3) and an increase on age classification precision was achieved. The results from the age reading inter-calibration exercise, conducted previously to the WKARBLUE3, revealed
an increase on the age classifications precision between participants, with an overall of $70 \%$ of agreement on advanced readers. Although, there are still issues on ageing this species, and the main assumptions to overcome those felt in the expertise of the readers. The main issues are: otoliths from some areas revealed to be more difficult to read (e.g. 27.2.a, 27.5.b); the first ring identification; edge type interpretation and false or double rings identification. During the WKARBLUE3 objective and more clear guidelines had been constructed. Thus, the main goal during the WKARBLUE3 has been to increase the ageing precision and that was achieved. Nonetheless, in order to increase the accuracy on age classifications, age validation studies to clarify growth rings pattern interpretation must be conducted.

The age-error matrixes, by quarter and area, resulting from the inter-calibration exercise are now available and can be used to correct the catch-at-age and survey data used for assessment. Furthermore, the impact of these uncertainties on age reading on the stock assessment results will be investigated.

### 2.15 Deviations from stock annex caused by missing information from Covid-19 disruption.

The one and only survey used for the SAM assessment, the International Blue Whiting Spawning Stock Survey (IBWSS) was not conducted in 2020, but resumed in 2021. The stock assessment this year followed the approach outlined in the Stock Annex.

The uncertainties on F and SSB in the terminal year are estimated lower in this year's assessment compared to last year's assessment with no survey in the terminal year.

### 2.18 Figures

Figure 2.2.1. Blue whiting landings in 2020, based on logbook data. The catches on the map constitute $98.9 \%$ of the ICES estimated catches. The $\mathbf{2 0 0} \mathbf{m}$ and 1000 m depth contours are indicated in blue.

Figure 2.2.2. Blue whiting catches per quarter 2020. The catches on the map are based on logbook data and constitute 98.9 \% of the ICES estimated catches. The total catches and percentages shown on each panel are also based on logbook data, and therefore deviate slightly from the ICES estimated catches pr. quarter. The $\mathbf{2 0 0} \mathbf{~ m}$ and $\mathbf{1 0 0 0} \mathbf{~ m}$ depth contours are indicated in blue.

Figure 2.3.1.1. Blue whiting. ICES estimated catches (' 1000 tonnes) in 2020 by ICES division and country.

B

Figure 2.3.1.2. Blue whiting.(A) ICES estimated catches (tonnes) of blue whiting by fishery subareas from 1988-2020 and (B) the percentage contribution to the overall catch by fishery subarea over the same period.

Figure 2.3.1.3. Blue whiting. Distribution of 2020 ICES estimated catches (in percentage) by quarter.

Figure 2.3.1.4. Blue whiting. Distribution of 2020 ICES estimated catches (in percentage) by ICES division area.

Figure 2.3.1.5. Blue whiting. ICES estimated catches (' 1000 tonnes) in 2020 by country.

Figure 2.3.1.6. Blue whiting. Distribution of 2020 ICES estimated catches (' 1000 tonnes) by ICES division and by quarter.

Figure 2.3.1.7. Blue whiting. Catch-at-age numbers (CANUM) distribution by quarter and ICES division for 2020.

Figure 2.3.1.1.1. Blue whiting. 2020 ICES catches (' 1000 tonnes) based on sampled or estimated distribution by ICES division.

Figure 2.3.1.2.1. Blue whiting. Mean length ( mm ) by age ( $0-10$ year), by quarter (1,2), by country for ICES division area 27.6.a. These data only comprises the 2020 ICES catch-at-age sampled estimates for ICES division 27.6.a.

Figure 2.3.2.1. Blue whiting. 2021 ICES preliminary catches (' 1000 tonnes) (Quarter 1 + Quarter 2) based on sampled or estimated distribution by ICES division.

Figure 2.3.2.2 Preliminary and final estimates of catch at age number by age and year.

Figure 2.3.3.1. Blue whiting. Catch proportion at age, 1981-2021. Preliminary values for 2021 have been used.

Figure 2.3.3.2. Blue whiting. Age disaggregated catch (numbers) plotted on log scale. The labels for each panel indicate year classes. The grey dotted lines correspond to $Z=0.6$. Preliminary catch-at-age data for 2021 have been used.

Figure 2.3.4.1. Blue whiting. Mean catch (and stock) weight ( kg ) at age by year. Preliminary values for 2021 have been used

Figure 2.3.7.1.1. Blue whiting. (A) Estimate of total biomass from the International blue whiting spawning stock survey. The black dots and error bands are StoX estimates with $90 \%$ confidence intervals. (B) Internal consistency within the International blue whiting spawning stock survey. The upper left part of the plots shows the relationship between log index-at-age within a cohort. Linear regression line shows the best fit to the log-transformed indices. The lower-right part of the plots shows the correlation coefficient ( $r$ ) for the two ages plotted in that panel. The background colour of each panel is determined by the $r$ value, where red equates to $r=1$ and white to $r<0$.

Figure 2.3.7.1.3. Blue whiting. Length (line) and age (bars) distribution of the blue whiting stock in the area to the west of the British Isles, spring 2017 (lower panel) to 2021 (upper panel). Spawning-stock biomass and numbers are given.

Figure 2.4.1.1. Blue Whiting. OSA (One Step Ahead) residuals (see Berg and Nielsen, 2016) from catch-at-age and the IBWSS survey 2004-2021 (no survey in 2020). Red (lighter) bubbles show that the observed value is less than the expected value. Preliminary catch data for 2021 have been used.

Figure 2.4.1.2 Blue whiting. Joint sample residuals (Process errors) for stock number and $F$ at age. Red (lighter) bubbles show that the observed value is less than the expected value. Preliminary catch data for 2021 have been used.

Figure 2.4.1.3. Blue whiting. Process errors expressed as deviation in instantaneous mortality at age by age and year.

## Residual catch

IBWSS

Figure 2.4.1.4. Blue whiting. The correlation matrix between ages for the catches and survey indices. Each ellipse represents the level curve of a bivariate normal distribution with the corresponding correlation. Hence, the sign of a correlation corresponds to the sign of the slope of the major ellipse axis. Increasingly darker shading is used for increasingly larger absolute correlations, while uncorrelated pairs of ages are depicted as circles with no shading. Preliminary catch data for 2021 have been used.

Figure 2.4.1.5. Blue whiting. Exploitation pattern by 5-years' time blocks. Preliminary catch data for 2021 have been used.

Figure 2.4.1.6. Blue whiting. Retrospective analysis of recruitment (age 1), SSB (tonnes), F and total catch using the SAM model. The 95\% confidence interval is shown for the most recent assessment.

Figure 2.4.1.7. Blue whiting. SAM final run: Stock summary, total catches, recruitment (age 1), F and SSB. The graphs show the median value and the $95 \%$ confidence interval. Catches for 2021 are preliminary.

Figure 2.4.1.8. Blue whiting. SAM final run: Comparison of the 2020 and 2021 stock assessments, shown with $95 \%$ confidence intervals. Catches for 2021 are preliminary.

Figure 2.4.3.1. Blue whiting. Comparison of SSB, $F$ and recruitment estimated by the assessment programs XSA, TISVPA and SAM. Catch values for 2021 are preliminary.

Figure 2.4.3.2. Blue whiting. Comparison of SSB, F and recruitment estimated by the official WGWIDE 2021 SAM model and an alternative version including the two surveys IESNS and IESSNS. Catch values for 2021 are preliminary.

Figure 2.8.1.1. Blue whiting young fish indices from five different surveys and recruitment index from the assessment, standardized by dividing each series by their mean. BarSea - Norwegian bottom-trawl survey in the Barents Sea, IESNS: International Ecosystem Survey in the Nordic Seas in May (1 and 2 is the age groups), IBWSS (Not updated in 2020): International Blue Whiting Spawning Stock survey (1 and 2 is the age groups), FO: the Faroese bottom-trawl surveys in spring, IS: the Icelandic bottom-trawl survey in spring, SAM: recruits from the assessment.
