## A. General

## A.1. Stock definition

The Norwegian spring-spawning herring (Clupea harengus) is the largest herring stock in the world. It is widely distributed and highly migratory throughout large parts of the NE Atlantic during its lifespan (Dragesund et al., 1997; Figure A.1.1). Formally, the description of the Norwegian spring-spawning herring stock is not linked to specific areas and the ICES advice applies to all areas where it occurs. By far the majority of the adult stock occurs in Divisions 2.a,b 5.a,b and 14.a. Juveniles of the stock have their nurseries in Division 1.a. In some years, small amounts of Norwegian springspawning herring can be found in adjacent areas mixing with other herring stocks during the feeding season.

It is a herring type with large number of vertebrae (Runnstrøm 1941), large size at age, large maximum size, different scale- (Lea 1929; Runnstrøm 1936) and otoliths shape (Einarsson 1951; Libungan et al. 2015) characteristics from other herring stocks and large variation in year-class strength.

## A.1.1 Mixing/separation of NSSH with/from other adjacent herring stocks (Lisa)

Suggest to have such a section. Write status based on workshop in Ireland November 2018 - and perhaps also other information??

Figure A.1.1. Current migration pattern of the adult part of the Norwegian spring-spawning herring (NSSH) and interactions with other surrounding stocks, i.e. Icelandic summer-spawning herring (ISSH), Faroese autumn-spawning herring (FASH), and Norwegian autumn-spawning herring (NASH) (from Pampoulie et al. 2015). NB!! Herring south of 62 are not visualised/described - suggest to use map that also includes e.g. North Sea herring!! - or rewrite!! Eydna checks ....

## A.2. Fishery and management

The fishery is regulated and carried out by the Coastal States. The TAC is set by the Coastal States and derived from an agreed long-term management strategy (Anon 2018). The Coastal States also agree on the allocation of the TAC into national quota. The fishery is carried out all year-round by purse-seines and pelagic trawlers. The catches are used for reduction purposes as well as human consumption with an increasing fraction used for human consumption during 2010-2020. The traditional fishing pattern follows the clockwise migration pattern of the herring. Changes in the migration pattern have occurred in the past and consequently also leading to changes in the fishery, following the fish. The most recent description of distribution and migration pattern of the stock derives from a Working Group established by the Coastal States (Anon, 2020), which covers the period 2013-2020 and is based on information from the fishery and research surveys.

The Norwegian spring-spawning herring is sometime caught mixed with other herring stocks (Figure 1). In the southern part along the Norwegian coast it can be mixed with North Sea herring. In Icelandic waters it can be mixed with Icelandic summerspawning herring and they are separated in the catches on basis of maturity stage and are assessed separately. In Faroese waters where NSS-herring can be mixed with a small local autumn-spawning stock and in Norwegian waters where it can be mixed with number of small local stocks, particularly autumn-spawners near Lofoten (Husebø et al. 2005), and the stocks are not separated in the catches and thereby assessed together.

Most of the catches consist of herring only and discarding is absent or very low. Bycatch of mackerel has been reported on the traditional fishing grounds, in years when there is considerable spatiotemporal overlap between herring and mackerel in the feeding areas.

## A.3. Ecosystem aspects (Eydna, Maxim)

## A.3.1. Spawning and recruitment

The herring spawns along the Norwegian west coast in February-March. Large variations in the north-south distribution of the spawning areas have been observed through the centuries (Devold 1963; Dragesund et al. 1997). The larvae drift north and northeast and distribute as 0 -group in fjords along the Norwegian coast and in the Barents Sea. The Barents Sea is by far the most important juvenile area for the large year classes (Dragesund 1970; Holst and Slotte 1998), which form the basis for the large production-potential of the stock. Some year classes are in addition distributed into the Norwegian Sea basin as 0-group. Examples of this are the 1950 and 2002 year classes. Most of the young herring leave the Barents Sea as 3 years old and feed in the northeastern Norwegian Sea for 1-2 years before recruiting to the spawning stock (Holst and Slotte, 1998). Large year classes typically mature at a higher mean age due to density-dependent growth (Toresen 1990; Holst 1996). However, exceptions occur and for example the 2002 year class was a large year class, with a fast growth rate and a relatively early maturation compared to other large year classes (ICES, 2010). Juveniles growing up in the Norwegian Sea grow faster than those in the Barents Sea and mature one year earlier (Runnstrøm 1936). When mature, the young herring starts joining the adult feeding migration in the Norwegian Sea.

Norwegian spring-spawning herring is one of the few stocks for which data have been collected over a very long period. Figure A.1.1.1 shows the dynamics of the stock in the past century indicated by assessments which go back to 1907.

The stock's size dynamic is governed by huge fluctuations in recruitment. A number of hypotheses have been suggested to explain the variability of recruitment. For example, larval survival and subsequent year-class strength in NSSH can be enhanced by early hatching time (Husebø et al., 2009), reduced cannibalism (Dalpadado et al., 2000), rapid displacement of larvae to the Barents Sea nursery area (Vikebø et al., 2010), and higher temperature in the Barents Sea (Toresen and Østvedt, 2000). Moreover, a recent study by Skagseth et al. (2015) shows that years with high recruitment coincide with predominantly southwesterly winds and weak upwelling in spring and summer, which lead to an enhanced northward coastal current during the larval drift period. Also in most peak recruitment years, low-salinity anomalies were observed to propagate northward during the spring and summer.

## A.3.2. Feeding and overwintering

The feeding migration starts just after spawning with the maximum feeding intensity and condition increase occurring from May until July-September (Homrum et al., 2016). The feeding migration is in general length dependent, meaning that the largest and oldest fish perform longer and typically more western migrations than the younger ones.

After the dispersed feeding migration the herring concentrate in one or more wintering areas in September-October. These areas shift periodically and since 1950 the stock has used at least 6 different wintering areas in different periods (Dragesund et al. 1997; Huse et al. 2010). During the 1950s and 1960s they were situated east of Iceland and since around 1970 in Norwegian fjords. From 2002 when the large year classes of 1998/98 started recruiting to the spawning stock a new wintering area was established off the Norwegian coast between $69^{\circ} 30^{\prime} \mathrm{N}$ and $72^{\circ} \mathrm{N}$ and in $2007 \backslash 2009$ no herring was observed in the fjords in winter. The stock has recently utilized this off-
shore wintering area but the survey covering the oceanic wintering area until 2007 (Survey 3 below) showed a strong decrease in the biomass in the wintering stock in the area and the fishery indicate that the wintering is now scattered with herring wintering both in fjords in northern Norway and in oceanic areas.

After wintering, the spawning migration starts around mid-January.

## A.3.3. Migration and trophic interaction

A characteristic feature of this herring stock is a very flexible and varying migration pattern. The migration is characterized as relatively stable periods and periods characterized by large changes occurring at varying time intervals (Dragesund et al. 1997; Huse et al. 2010). The changes may or may not be correlated between the major distribution areas: Spawning, feeding and wintering. Changes in migration pattern are frequently observed in association with large year classes entering the adult stock. At present we see a period of large changes in both the wintering and feeding area.

In May the herring is migrating westwards into the Norwegian Sea for summer feeding and the main concentrations are found in the central part of this area as shown by the International Ecosystem Survey in Nordic Seas (IESNS). In July the herring are spread out over a wide area feeding around the fringes of the Norwegian Sea, particularly in the northern and western region, while almost no herring are observed in the central region. This is shown by the Ecosystem Summer Survey in Nordic Seas (IESSNS), which in the latest years has indicated for example the most westerly distribution of the herring north of Iceland observed since the collapse of the stock in the late 1960s (ICES 2015). The herring is occupying the feeding grounds at least throughout August according to the fishery and moves then progressively eastwards to the overwintering areas. At the beginning of the feeding season the herring on the western feeding grounds are in better condition (Homrum et al. 2016), probably because these have started their feeding migration earlier. As the feeding season proceeds the condition in east and west is more similar, but in October in the latest years the condition is again better in west than in east, indicating that fish in the west may not yet have started their migration for the winter areas. Since around 2012, there is an indication from the fishery for a prolonged duration of the stock on the feeding grounds and possibly oceanic overwintering of part of the stock in the mid and eastern part of the Norwegian Sea. This remains to be explored in a more quantitative manner.

## B. Data

## B.1. Commercial catch (Are)

## B.1.1. Nominal catch

The catches used in the assessment are the catches provided by the Working Group members.

## B.1.2. Catch-at-age

From each country participating in the herring fishery exists a data delivery sheet containing at minimum information about total catch in tons by quarter of the year and ICES area. If the fleet has taken samples then catch in numbers by age, mean weight at age and mean length-at-age for each quarter of the year and ICES area are provided. Catch in tonnes by ICES rectangles and quarters are also reported. These sheets are combined into one file. Catches from quarters and areas with no associated biological samples have then to be allocated to sampled ones. To do so positions of the catches by fleet are plotted, to see where the fleet was operating. Mean weights and mean lengths behind the sampled catches are also plotted. On the basis on these inspections allocations are done. Then the program SALLOC (ICES 1998/ACFM:18) is used to calculate the total international catch in numbers. Output from SALLOC is total catches in numbers by age as well as by quarters and areas. Intercatch is not used since it is not possible to record catch data from two different stocks of the same species in the same ICES area. Norwegian spring-spawning herring is sometimes caught in the same areas as other herring stocks, e.g. in 4.a and 5.a.

## B.1.3. Weight at age of the catch

Annual weight at age of the catch originate from national sampling programmes of the commercial catches. They are provided by most fishing nations each year on a quarterly basis. The weight at age of the catch used in the assessment is the average of the different nations weighted over the associated catch numbers. Mean weights by age in the catch by age is also output from SALLOC.

## B.1.4. Length-at-age of the catch

Mean length by age in the catch is calculated the same way as mean weight at age of the catch. It is not used in the assessment. Mean length by age in the catch is also output from SALLOC.

## B.2. Biological parameters

## B.2.2. Weight at age of the stock

Up to 2008, weight of age of the stock was derived from the Norwegian survey in the wintering area. The survey was stopped in 2008. From 2009 onwards annual updates of weight at age in the stock is estimated from Norwegian commercial catches taken in the overwintering area in January.

## B.2.3. Natural mortality

In the 2016 benchmark assessment it was decided to continue to use natural mortality $\mathrm{M}=0.15$ for ages 3 and older and $\mathrm{M}=0.9$ for ages $0-2$ in all years from 1988 onwards. The basis for using these values is provided below.

In a working group report from 1996 (ICES 1996/ASSESS:14), it says that values of M assumed by the Working Group were 0.16 for ages 3 and older during the years 1950 to 1970 while 0.13 for the years 1971 and subsequently. Attempts to estimate natural mortality from tagging information (Hamre, WD 1997; Patterson, WD 1997a; Tjelmeland, WD 1997) were highly consistent with these values in the range 0.13 to 0.16 , but the Working Group did not consider that this parameter could be estimated with sufficient precision to justify a discrimination between levels of 0.13 and 0.16. Consequently, it was decided to predicate the assessment model estimates on an arbitrarily chosen $\mathrm{M}=0.15$ for ages 3 and older.
In the Working Group report from 1992 (ICES 1992) a comparison of acoustic estimates for year classes 1983-1985 and 1988 as 0-group, and the same year classes as 3 year old (VPA) gave an average annual $\mathrm{M}=0.88$, so $\mathrm{M}=0.9$ was used for ages $0-2$. Mean value of M for these age groups estimated by de Barros (1995) was consistent with this value. Hence M=0.9 has by used since the 1992 assessment for ages $0-2$.

## B.2.4. Maturity-at-age

In 2010 the method for estimating maturity-at-age in the stock assessment of NSSH was changed based on work done by the "workshop on estimation of maturity ogive in Norwegian spring-spawning herring" (WKHERMAT; ICES, 2010a). The method which was adopted by WGWIDE in 2010 (ICES, 2010b) is based on work by Engelhard et al. (2003) and Engelhard and Heino (2004). They developed a method to backcalculate age at maturity for individual herring based on scale measurements and used this to construct maturity ogives for the year classes 1930-1992.

The NSSH has irregular recruitment pattern with a few large year classes dominating in the stock when it is on a high level. Most of the year classes are, however, relatively small and referred to as "normal" year classes. The back-calculation dataset indicates that maturation of the large year classes is slower than for "normal" year classes.

WKHERMAT and WGWIDE considered the dataset derived by back calculation as a suitable candidate for use in the assessment because it is conceived in a consistent way over the whole period and can meet standards required in a quality-controlled process. However, the back-calculation estimates cannot be used for the most recent years since all year classes have to be fully matured before the calculation can be made. Therefore, assumptions have to be made for the recent year classes. For recent year classes, WGWIDE (ICES, 2010) decided to use average back-calculated maturity for "normal" and "big" year classes, respectively and thereby reducing maturity-atage for ages 4,5 and 6 when strong year classes enter the spawning stock. The default maturity ogives used for "normal" and "big" year-classes are given in the text table below.

The default maturity ogives used for 'normal' and strong year classes are given in the text table below.

| AGE | $\mathbf{0}$ | $\mathbf{1}$ | $\mathbf{2}$ | $\mathbf{3}$ | $\mathbf{4}$ | $\mathbf{5}$ | $\mathbf{6}$ | $\mathbf{7}$ | $\mathbf{8}$ | $\mathbf{9}$ | $\mathbf{1 0}$ | $\mathbf{1 1}$ | $\mathbf{1 2}$ | $\mathbf{1 3}$ | $\mathbf{1 4}$ | $\mathbf{1 5}$ |
| :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- |
| normal <br> yc | 0 | 0 | 0 | 0 | 0.4 | 0.8 | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1 |
| strong <br> yc | 0 | 0 | 0 | 0 | 0.1 | 0.6 | 0.9 | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1 |

Assumed values should be replaced by back-calculated values in the annual assessments for each year where updated values are available.

The maturity ogives used in the present assessment are presented in the WGWIDE report.

## B.3. Surveys (Are, Maxim, Sigurvin, Eydna)

A number of surveys on this stock have been carried out in the Norwegian Sea and Barents Sea to estimate the size of the stock, its age composition or the recruitment to the stock. Some of the surveys have stopped but data are still used in the assessment

The acoustic abundance estimates are calculated with the software StoX (ICES 2016a), which provide estimates of precision that can be implemented in new stock assessment models. In 2015 and 2016 some of the survey series were re-estimated back to 2008?? with StoX. At WGWIDE 2020 it was decided to use the mean value of abundance of bootstrap with 1000 replicates. Only these mean values are provided in the tables in the annex, but the CV from the bootstrap is also used in the assessment.

## B.3.1. Survey 1. Norwegian acoustic survey on spawning grounds in February/March

Acoustic surveys on the spawning grounds of Norwegian spring-spawning herring (NSS) have been carried out from 1988 onwards, with some breaks e.g. in 2001-2004 and 2009-2014 (WD10). The majority of NSS herring spawns on banks along the Norwegian coast from Møre ( $\approx 62^{\circ} \mathrm{N}$ ) to Vesterålen ( $\approx 69^{\circ} \mathrm{N}$ ) in mid-February to midMarch (Figure B.3.1.1). However, the timing and location of spawning within this area and period have varied between years, e.g. there seems to be a trend towards earlier spawning in more recent years. This time-series has been re-estimated (see 2.2.2 in WKPELA 2016). The new abundance estimates are presented in Table B.3.1.1. Data were not available for the years 1990 and 1991 on the needed format so they could not be re-estimated.

This survey is used in the main assessment.

## B.3.2. Survey 2. Norwegian acoustic survey in November/December

The survey was carried out by Norway from 1992 to 2007 in the Norwegian fjords where the adult herring overwinter (Figure B.3.2.1). After 2003 also the oceanic areas north of Lofoten/Vesterålen were included in the survey to take account of changes in the wintering area. The fjordic coverage was ceased during the winter 2007/2008 because the herring had totally left the fjords. The indices from this survey have not been re-estimated. The results of this survey are shown in Table B.3.2.1.

This survey is not used in the main assessment.

## B.3.3. Survey 3. Norwegian acoustic survey in January

This survey was carried out by Norway in the fjords in the period 1991-1999. The indices from this survey have not been re-evaluated.

The results of the survey in the wintering area in January can be found in Table B.3.3.1.

This survey is not used in the main assessment.

## B.3.4. Survey 4 and 5. International ecosystem survey in the Nordic Seas

The international ecosystem survey in the Nordic Seas (IESNS) is aimed at observing the pelagic ecosystem, focusing on herring, blue whiting, zooplankton and hydrography. The survey, carried out annually since 1995, is coordinated by the ICES WGIPS (ICES 2020) and is a cooperative effort by Faroes, Iceland, Norway, Russia, and the EU (Denmark, Germany, Ireland, The Netherlands, Sweden and UK). This trawlacoustic survey supplies the most important fishery independent time-series for the assessment of NSSH and also a time-series for young blue whiting in the juvenile areas.

The age-disaggregated time-series of abundance of Norwegian spring-spawning herring for the Barents Sea are presented in Table B.3.4.1. No data exist for 2003, 2004 and 2020. The indices since 2009 have been derived by StoX.

The age-disaggregated time-series of abundance of NSSH in the Norwegian Sea are presented in Table B.3.4.2. The indices since 2009 have been derived by StoX.

The survey covers the entire stock during its migration on the feeding grounds, the adults in the Norwegian Sea and juveniles in the Barents Sea. An example of the coverage of the survey (2015) is given in Figure B.3.4.1.

These surveys are used in the main assessment.

## B.3.5. Survey 6 and 7. Joined Russian-Norwegian ecosystem autumn survey in the Barents Sea

The survey consists of a trawl survey catching 0 -group herring among other species and an acoustic survey estimating one and two year old herring. In 2001, the Working Group decided to include data on immature herring obtained during the RussianNorwegian survey in August-October in estimating the younger year classes in the Barents Sea

The youngest age groups ( $0-3+$ ) of the Norwegian spring-spawning herring stock are found in the Barents Sea at irregular intervals. It is difficult to assess the stock size during autumn, due to various reasons. The age groups 1-3 are found mixed with $0-$ group herring and are difficult to catch in the sampling trawl used in this survey. The stock size estimates of herring are therefore considered less reliable than those for capelin and polar cod. An example of the distribution of young herring is shown in Figure B.3.5.1. An example of the distribution of 0-group herring is presented in Figure B.3.5.2.

The results from these surveys on 0-group herring are given in Table B.3.5.1 (survey 7). The results for the 1 to 3 age groups are given in Table B.3.5.2 (survey 6).

These surveys are not used in the main assessment.

## B.3.6 Survey 8 Norwegian herring larvae survey on the Norwegian shelf

A Norwegian herring larvae survey has been carried out on the Norwegian shelf since 1981 during March-April. The objectives of the survey are to map the distribution of herring larvae and other fish larvae on the spawning grounds on the Norwegian shelf and to collect data on hydrography, nutrients, chlorophyll and
zooplankton. The larval indices can be used as indicator of the size of the spawning stock. Two indices are available from this survey.

The re-evaluated indices with associated CVs for the herring larvae are presented in Table B.3.6.1. Examples of the distribution of the herring larvae are given in Figure B.3.6.1.

This survey is not used in the main assessment.

## B.3.7 Survey 9 International ecosystem summer survey in Nordic Sea (IESSNS)

This ecosystem survey initiated in 2004 by Norway and have since then been gradually expanded in geographical coverage and scientific complexity (e.g. Nøttestad and Jacobsen 2009). Since 2010 the survey coverage was expanded further with participations of vessels from Iceland and the Faroese in addition to two vessels from Norway. The main objective of the survey is to study abundance, spatio-temporal distribution, aggregation and feeding ecology of Northeast Atlantic mackerel, Norwegian springspawning herring, blue whiting and other pelagic species in relation to oceanographic conditions, prey communities and marine mammals. Two different types and independent abundance estimates for herring can be derived from the survey, an acoustic estimate, and swept-area estimate from predefined surface trawl stations.

The acoustic estimates for herring since 2009 are shown in Table B.3.7.1. In 2011 and 2014 the coverage was not complete with regard to herring (Nøttestad et al. 2014). An example of the coverage of the survey (2020) is given in Figure B.3.7.1.

This survey is not used in the main assessment.

## B.4. Commercial CPUE

No commercial CPUE data are used in the assessment.

## B.5. Other relevant data (Aril?)

With the exception of 1999, 2001 and 2005, tagging has been carried out annually between 1975 and 2007. Since 2008 no tagging has been carried out.

The use of the tagging data in the assessment was discontinued since 2006 due to a small number of recaptures. This comes as a result of too low tag density in the stock given the high stock size and amount of fish screened for tags.

## C. Historical Stock Development

## C1. The main assessment tool XSAM

A model template based on a state space model and structural time-series models for fish stock assessment have been developed and is described in Aanes 2016a and 2016b. The framework builds on well-known statistical models, but offers the possibility to utilize prior knowledge of sampling errors entering the observation models. The framework has been given the name XSAM and WKPELA 2016 decided to use this as the main assessment tool. The setup and usage of XSAM follows:

1) Software used: R and TMB. Documented source code is available at the SharePoint site for WGWIDE.
2) Model options:
i. Time span: 1988-present date
ii. Age span: 2-12+
iii. There is no empirical evidence for $\sigma_{\mathrm{a}}^{2}>0$, therefore $\sigma_{\mathrm{a}}^{2}$ is set to 0 and effectively one level in the hierarchy for the latent state of effort is omitted.
iv. Effort is modelled as an $\operatorname{AR}(1)$ process
v. Selectivity is modelled as a multivariate $\operatorname{AR}(1)$ process
vi. $\quad a_{m}=11$, i.e. the selectivity in fishing mortality is assumed constant for ages 11 and above
vii. Catch-at-age as reported by WGWIDE
viii. IESNS in the Norwegian Sea (Fleet 5): StoX estimates, age specific qup to age 11, q-plateau at ages above 11
ix. Spawning survey (Fleet 1): StoX estimates, age specific qup to age 8 , qplateau at ages above 8
x. Observation model 5 which implies estimating a common scaling factor ${ }^{h}$ across datasets
a) Use sampling variances for catch-at-age as estimated by ECA (Salthaug and Aanes 2015, Hirst et al. 2012)
b) Use sampling variances for Fleet 5, Fleet 4 and Fleet 1 as estimated by StoX
c) The model uses the sum of declared unilateral quotas as input for total catch.
d) The plusgroup is modelled as a dynamic pool.
3) Analyses are restricted to the years 1988-present. The last year is the year after the last year with catch data. The fishing mortality in the last year is based on the sum of declared catches.
4) Age range for the analyses is $2-12+$, but can in principle be extended to any age range
5) Natural mortality is assumed at 0.9 for ages 0,1 and 2 and 0.15 for all older ages.
6) Input data: Listed in Table C.1.1

Table C.1.1

| TYPE | Name | Year range | Age range | Variable from year-to-year Yes/No |
| :---: | :---: | :---: | :---: | :---: |
| Caton | Catch in tonnes | 1988-last data year | -- | Yes |
| Canum | Catch-at-age in numbers | 1988-last data year | 2-12+ | Yes |
| Weca | Weight at age in the commercial catch | 1988-last data year | 2-12+ | Yes |
| West | Weight at age of the spawning stock at spawning time. | 1988-last data year | 2-12+ | Yes |
| Mprop | Proportion of natural mortality before spawning | 1988-last data year | 2-12+ | No |
| Fprop | Proportion of fishing mortality before spawning | 1988-last data year | 2-12+ | No |
| Matprop | Proportion mature at age | 1988-last data year | 2-12+ | According to WKHERMAT see B.2.4 |
| Natmor | Natural mortality | 1988-last data year | 2-12+ | No |
| CatchPred | Prediction of total catch in tonnes | Last data year + 1 | -- | Yes |

Tuning data:

| TYPE | NAME | Year range | Age range |
| :---: | :---: | :---: | :---: |
| Tuning fleet 1 | Norwegian acoustic survey on spawning grounds in February/Match | $\begin{aligned} & \text { 1988-1989, 1994- } \\ & \text { 1996, 1998- } \\ & \text { 2000,2005-2008, } \\ & \text { 2015-last data } \\ & \text { year +1 } \end{aligned}$ | 3-12+ |
| Tuning fleet 4 | IESNS in the Barents <br> Sea | 1991- last data year +1 | 2 |
| Tuning fleet 5 | IESNS in the <br> Norwegian Sea | 1996-last data year +1 | 3-12+ |

## The likelihood function

The model is described in in detail in Aanes 2016a and 2016b implicitly including the likelihood function with all its components. Each component in the likelihood function and the parameters involved it is described in this section. The model includes the components fishing mortality, recruitment and observations. The fishing mortality is modelled as a structural time-series model and the values are latent variables with underlying processes. The recruitment is modelled as a random variable. The parameters to be estimated are the parameters characterizing the latent processes (described below) and the initial values (the numbers-at-age the first year, except for the recruiting age which is modelled as random variables). See Aanes 2016a and 2016b for further details. The likelihood components are summarized in table 1 after the detailed description.

## C1.1 Fishing mortality

The fishing mortality is a random variable following a structural time-series model with the following components:

First the fishing mortality is modelled as a separable model with noise

$$
\log \left(F_{a, t}\right)=\mu_{a, t}^{F}+\delta_{a, t}^{(1)}=U_{a, t}+V_{t}+\delta_{a, t}^{(1)}
$$

where

$$
\left\{\delta_{a, t}^{(1)}\right\}_{a=a_{\text {min }}, \ldots, A} \sim \operatorname{MVN}\left(\mathbf{0}, \mathbf{\Sigma}^{(1)}\right)
$$

and here $\boldsymbol{\Sigma}^{(1)}=\sigma_{1}^{2} \mathbf{I}$
Writing $\log \left(\boldsymbol{F}_{t}\right)=\left\{\log \left(F_{a, t}\right)\right\}_{a=a_{\text {min }, \ldots, A_{m}}}$, the likelihood component for fishing mortality is

$$
l_{F}=0.5 T \log (2 \pi)\left|\boldsymbol{\Sigma}^{(1)}\right|+\sum_{t=1}^{T}\left(\log \left(\boldsymbol{F}_{t}\right)-\log \left(\boldsymbol{F}_{t}^{*}\right)\right)^{\prime}\left(\boldsymbol{\Sigma}_{t}^{(1)}\right)^{-1}\left(\log \left(\boldsymbol{F}_{t}\right)-\log \left(\boldsymbol{F}_{t}^{*}\right)\right)
$$

where $\boldsymbol{F}_{t}^{*}$ are the model predictions of the fishing mortality at time $t$. This component includes the fixed parameter $\sigma_{1}^{2}$

The underlying components are selectivity, realized effort and effort is described in the following.

## C1.1.1 Selectivity

The selectivity is modelled as a multivariate 1. order autoregressive process

$$
U_{a, t}=\alpha_{a U}+\beta_{U} U_{a, t-1}+\delta_{a, t}^{(2)}, \quad a_{\text {min }} \leq a \leq a_{m}
$$

and is set constant for ages older than $a_{m}$. Note that $\alpha_{a U}$ is age specific but $\beta_{U}$ is constant across ages. Above age $a_{m}$ the selectivity is set constant

$$
U_{a, t}=U_{a_{m}, t}, \quad a \geq a_{m}
$$

with the constraint:

$$
\sum_{a=1}^{a_{m}} U_{a, t}=0
$$

Since $\left\{\delta_{a, t}^{(2)}\right\}_{a=a_{\text {min }} \ldots, \ldots, a_{m}-1} \sim \operatorname{MVN}\left(\mathbf{0}, \boldsymbol{\Sigma}^{(2)}\right)$ and writing $\boldsymbol{U}_{t}=\left\{U_{a, t}\right\}_{a=a_{m i n}, \ldots, a_{m}-1^{1}}$, the likelihood component is

$$
l_{s}=0.5(T-1) \log (2 \pi)\left|\boldsymbol{\Sigma}^{(2)}\right|+\sum_{t=2}^{T}\left(\boldsymbol{U}_{t}-\boldsymbol{U}_{t}^{*}\right)^{\prime}\left(\boldsymbol{\Sigma}_{t}^{(2)}\right)^{-1}\left(\boldsymbol{U}_{t}-\boldsymbol{U}_{t}^{*}\right)
$$

where $\boldsymbol{U}_{t}^{*}$ are the model predictions of the selectivity at time $t$. Here $\boldsymbol{\Sigma}^{(2)}=\sigma_{2}^{2} \mathbf{I}$ (time invariant with one parameter), such that this component includes the fixed parameters $\left\{\alpha_{a U}\right\}_{a=a_{\text {min }}, \ldots, a_{m}-1}, \beta_{U}$, and $\sigma_{2}^{2}$.

## C1.1.2 Realized effort

The "realized" effort $V_{t}$ is a latent variable depending on the underlying effort $Y_{t}$ according to

$$
V_{t}=Y_{t}+\delta_{t}^{(3)}
$$

where $\delta_{t}^{(3)} \sim N\left(0, \sigma_{3}^{2}\right)$.

$$
l_{v}=0.5 T \log \left(2 \sigma_{3}^{2} \pi\right)+\sum_{t=1}^{T} \frac{\left(V_{t}-V_{t}^{*}\right)^{2}}{2 \sigma_{3}^{2}}
$$

where $V_{t}^{*}$ is the model prediction of the effort. This component includes the fixed parameter $\sigma_{3}^{2}$.

As noted in Aanes (2016a), the herring data does not give any support to estimate this process, since $\log \left(\sigma_{3}^{2}\right)$ tends to -infinity, or $\sigma_{3}^{2}$ tends to 0 , and convergence is not obtained. This means that this component excluded in the analysis presented here.

## C1.1.3 Effort

Effort $Y_{t}$ is a latent variable following an $\operatorname{AR}(1)$ model

$$
Y_{t}=\alpha_{Y}+\beta_{Y} Y_{t-1}+\delta_{t}^{(4)}
$$

where $\delta_{t}^{(4)} \sim N\left(0, \sigma_{4}^{2}\right)$ and has likelihood component

$$
l_{y}=0.5(T-1) \log \left(2 \sigma_{4}^{2} \pi\right)+\sum_{t=2}^{T} \frac{\left(Y_{t}-Y_{t}^{*}\right)^{2}}{2 \sigma_{4}^{2}}
$$

where $Y_{t}^{*}$ is the prediction given by the model for effort. The fixed parameters are $\alpha_{Y}$, $\beta_{Y}$ and $\sigma_{4}^{2}$.

## C1. 2 Recruitment

Although the framework allows for a flexible definition of the recruits, the log recruits at age $a_{\min }$ are here modelled as a random process $R_{t} \sim N\left(\mu_{R}, \sigma_{R}^{2}\right)$ such that the likelihood component becomes

$$
l_{R}=0.5 T \log \left(2 \sigma_{R}^{2} \pi\right)+\sum_{t=1}^{T} \frac{\left(R_{t}-R_{t}^{*}\right)^{2}}{2 \sigma_{R}^{2}}
$$

where $R_{t}^{*}$ are the model predictions of log recruitment at time $t$. The fixed parameters are mean $\log$ recruitment $\mu_{R}$ and the variance $\sigma_{R}^{2}$.

## C1.3 Observations

## C1.3.1 Catch-at-age

The catch vector at time $t$ is $\log \left(\boldsymbol{C}_{t}\right)=\left\{\log \left(C_{a, t}\right)\right\}_{a=a_{\text {min }, \ldots, A}}$ and the likelihood component is

$$
l_{C}=0.5 \log (2 \pi) \sum_{t=1}^{T}\left|\boldsymbol{\Sigma}_{t}^{c}\right|+\sum_{t=1}^{T}\left(\log \left(\boldsymbol{C}_{t}\right)-\log \left(\widehat{\boldsymbol{C}}_{t}\right)\right)^{\prime}\left(\boldsymbol{\Sigma}_{t}^{c}\right)^{-1}\left(\log \left(\boldsymbol{C}_{t}\right)-\log \left(\widehat{\boldsymbol{C}}_{t}\right)\right)
$$

Where are the observed catch-at-age and

$$
C_{a, t}=\frac{F_{a, t}}{Z_{a, t}}\left(1-e^{-Z_{a, t}}\right) N_{a, t}
$$

## C1.3.2 Abundance indices

For each fleet $f$

$$
\begin{gathered}
\log \left(\boldsymbol{I}_{t}^{f}\right)=\left\{\log \left(I_{a, t}^{f}\right)\right\}_{a=a_{\min n}, \ldots, A} \\
l_{I}^{f}=0.5 \log (2 \pi) \sum_{t=1}^{T}\left|\mathbf{\Sigma}_{t}^{f}\right|+\sum_{t=1}^{T}\left(\log \left(\boldsymbol{I}_{t}^{f}\right)-\log \left(\widehat{\boldsymbol{I}}_{t}^{f}\right)\right)^{\prime}\left(\mathbf{\Sigma}_{t}^{f}\right)^{-1}\left(\log \left(\boldsymbol{I}_{t}^{f}\right)-\log \left(\hat{\boldsymbol{I}}_{t}^{f}\right)\right)
\end{gathered}
$$

Where $\widehat{\boldsymbol{I}}_{t}^{f}$ are the observed abundance indices at age for fleet $f$

$$
I_{a, t}=q_{a}^{f} \mathrm{~N}_{a, t} \exp \left(-\delta_{t}^{f} \mathrm{Z}_{a, t}\right)
$$

For each fleet, the fixed parameters are $\left\{q_{a}^{f}\right\}_{a=a_{m i n}, \ldots, a_{m}^{f}}$, where $q_{a}^{f}=q_{a_{m}^{f}}^{f}$, for $a \geq a_{m}^{f}$ (i.e. the age at which the catchability is constant sometimes called "q-plateau").

For both catch-at-age and abundance indices at age there are optionally parameters in the observation errors that can be estimated. See Observation error below for details.

Table 1. Summary of likelihood components. In addition to the parameters in the table, the model depend on the initial values of abundance which enters through the model for catch-at-age and possibly abundance indices at age (provided that abundance indices are available in the first year of analysis)

| Component | Variable | Description | Fixed parameters | Likelinood COMPONENT |
| :---: | :---: | :---: | :---: | :---: |
| Fishing mortality F | $\left\{\log F_{a, t}\right\}_{a=\underset{t=1, \ldots, T}{a},}^{a_{\min , \ldots, A_{m}},}$ | Random | $\sigma_{1}^{2}$ | $l_{F}$ |
| F: Selectivity | $\left\{U_{a, t}\right\}_{a=a_{\min }, \ldots, a_{m}-1,}^{t=1, \ldots, T},$ | Random | $\left\{\alpha_{a U}\right\}_{a=a_{m i n}, \ldots, a_{m}-1}, \beta_{U}$ and $\sigma_{2}^{2}$ | $l_{s}$ |
| F: Realized effort | $\left\{V_{t}\right\}_{t=1, \ldots, T}$ | Random | $\sigma_{3}^{2}$ | $l_{v}$ |
| F: effort | $\left\{Y_{t}\right\}_{t=1, \ldots, T}$ | Random | $\alpha_{Y}, \beta_{Y}, \sigma_{4}^{2}$ | $l_{y}$ |
| Recruitment | $\left\{R_{t}\right\}_{t=1, \ldots, T}$ | Random | $\mu_{R}$ and $\sigma_{R}^{2}$ | $l_{R}$ |
| Catch-at-age | $\left\{C_{a, t}\right\}_{\substack{a=a_{m i n}, \ldots, \ldots, T}},$ | Observation | Optionally elements in $\boldsymbol{\Sigma}_{t}^{c}$ | $l_{C}$ |
| Abundance indices | $\left\{I_{a, t}^{f}\right\}_{a=a_{\min }^{f}, \ldots, A^{t=1, \ldots, T}}^{f},$ | Observation | $\left\{q_{a}^{f}\right\}_{a=a_{\text {min } n, \ldots, a_{m}^{f}}}$ <br> Optionally elements in $\boldsymbol{\Sigma}_{t}^{f}$ | $\left\{l_{I}^{f}\right\}_{f=1 \ldots, n_{f}}$ |

## C1.4 Joint and marginal likelihood

Writing $\theta, y$ and $x$ for the fixed parameters, random variables (latent states) and observations, respectively, the joint negative log likelihood for the model is

$$
l=-\log (f(\theta, y, x))=l_{y}+l_{v}+l_{s}+l_{F}+l_{R}+l_{C}+\sum_{f=1}^{n_{f}} l_{I}^{f}
$$

where $n_{f}$ is the number of fleets (i.e. number of sets of abundance indices at age) applied in the analysis.

The inference is based on the marginal likelihood, and the negative marginal log likelihood for the observations is

$$
l_{M}=-\log [f(\theta, x)]=-\log \left[\int f(\theta, y, x) d y\right]
$$

which is minimized. Note that in general the likelihood components for the observations $l_{c}+\sum_{f=1}^{n_{f}} l_{I}^{f}$ is NOT the same as the marginal likelihood for the observations $l_{M}$. Therefore, interpretation of the single likelihood components should be made by some care. Remaining details are given in Aanes 2016a and Aanes 2016b.

## C1.5 Observation error

For observations from catch and survey on the same form, i.e. abundance/numbers-at-age and time, the structure of the observation error for such data can be generically specified. For observation dataset $O$ the observation error for a specific year is $\boldsymbol{\Sigma}^{\prime \boldsymbol{O}}$ and is decomposed as follows

$$
\boldsymbol{\Sigma}^{\prime \boldsymbol{O}}=(\sqrt{\mathbf{h}} \cdot \boldsymbol{\sigma})(\sqrt{\mathbf{h}} \cdot \boldsymbol{\sigma})^{t} \mathbf{R}
$$

Where $\mathbf{h}=\left(h_{1}, \ldots, h_{A} o\right)^{t}$ is a scaling-factor of the covariance, $\boldsymbol{\sigma}=\left(\sigma_{1}, \ldots, \sigma_{A} o\right)^{t}$ the standard deviations (i.e. standard errors), and $\mathbf{R}$ is the $A^{0} \times A^{0}$ dimensional correlation matrix and $A^{0}$ the dimension (i.e. number of ages) for the observations for a spe-
cific year. In all cases considered here, only one scaling factor for each dataset is considered, i.e. $h_{i}=h \forall i$, such that

$$
\boldsymbol{\Sigma}^{\prime \boldsymbol{O}}=\mathrm{h} \boldsymbol{\Sigma}^{\boldsymbol{O}}
$$

such the error structure is completely determined by $\boldsymbol{\Sigma}^{\boldsymbol{0}}$ up to the scaling constant $h$. A summary of different formulations of observation models is given in Aanes 2016a and 2016b and WGWIDE decided that the data available at WKPELA gave most support for observation model 5, i.e. use sampling errors to parameterize $\boldsymbol{\Sigma}^{\boldsymbol{0}}$, and estimate a common scaling factor $h$ across datasets.

## C2. Exploratory assessment tool TASACS

This is the assessment method introduced by the benchmark in 2008 (ICES 2008), as used by WGWIDE in 2015. Since 2008, only minor amendments have been made to the software, but data have been revised on several occasions, also for the present benchmark. After the change of assessment model in the 2016 benchmark TASACS is annually run as an exploratory assessment by WGWIDE.

Software used: TASACS (Skagen and Skålevik, 2012). Last update 21.01.2016.
Model options used: VPA, dynamic pool plus group, fitted to 7 age structured surveys and one biomass survey, with manual weighting of data.

Analyses are restricted to the years 1988-present. The last year is the year after the last year with catch data. The fishing mortality in the last year is assumed equal to the last catch data year.

Age range for the analyses is $0-15+$
Natural mortality is assumed at 0.9 for ages 0,1 and 2 and 0.15 for all older ages.
Input data: Listed in Table C.2.1
The surveys (some of them revised with the StoX software in 2016) are described and tabulated in Section B3 and summarized in Table C.2.2. The text table below shows assumed fraction of fishing mortality and natural mortality for each of the agestructured surveys (fleets), and the age from which catchability is independent of age.

|  | FLEET $1$ | $\begin{aligned} & \text { FLEET } \\ & 2 \end{aligned}$ | $\begin{aligned} & \text { FLEET } \\ & 3 \end{aligned}$ | $\begin{aligned} & \text { FLEET } \\ & 4 \end{aligned}$ | $\begin{aligned} & \text { FLEET } \\ & 5 \end{aligned}$ | $\begin{aligned} & \text { FLEET } \\ & 6 \end{aligned}$ | $\begin{aligned} & \text { FLEET } \\ & 7 \end{aligned}$ |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| Prop F \& M before survey | 0.17 | 0.91 | 0.17 | 0.41 | 0.41 | 0.70 | 0.70 |

| First age <br> with flat | 11 | 10 | 10 | 2 | 11 | 2 | 0 |
| :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- |
| catchability |  |  |  |  |  |  |  |

The smallest measurable amount is set at 0.001 for all surveys and catch numbers-atage. The oldest age is handled as a plus group in surveys $1,2,3$ and 5 , and in the catch numbers-at-age.

## Objective function:

The stock numbers are back-calculated from survivor numbers. Estimated survivor numbers are those at the end of the last catch data year, or the end of the year where the year class is at oldest true age. The survivor numbers are model parameters that are estimated by fitting modelled survey data to observations. The modelled survey indices U are derived from the corresponding stock numbers N as
$\mathrm{U}=\mathrm{q}^{*} \mathrm{~N}$. Each catchability q is age and fleet specific but assumed constant over years. The objective function is a sum of weighted squared log survey residuals, including residuals from the larval survey as index of SSB:
$\mathrm{O}=\sum_{\mathrm{a}, \mathrm{y}, \mathrm{fl}} \mathrm{w}(\mathrm{a}, \mathrm{y}, \mathrm{fl}) * \log \{\mathrm{U}(\mathrm{a}, \mathrm{y}, \mathrm{fl}) /(\mathrm{q}(\mathrm{a}, \mathrm{fl}) * \mathrm{~N}(\mathrm{a}, \mathrm{y}))\}+$
$\sum_{\mathrm{yWSSB}}(\mathrm{y}) * \log \left\{\mathrm{U}_{\text {SSB }}(\mathrm{y}) /\left(\mathrm{q}_{\mathrm{SSB}} * \operatorname{SSB}(\mathrm{y})\right)\right\}$
Optimization (minimization of the objective function as functional of the parameters) is done by a searching routine.

The weighting $\mathrm{w}(\mathrm{a}, \mathrm{y}, \mathrm{fl})$ is either 1 or 0 , as described below; weighting according to error variance is not used.

Except for the plus group, catch data are not modelled, and are not included in the objective function. Catches from the plus group could have been included in the objective function, but that is not done in the standard conditioning.

Some survey observations are excluded by giving them zero weight. The principle is that if the survey contributes mostly noise to the assessment it is not included. In addition, when conflicting information appears between different surveys, it is attempted, as far as possible, to use expert knowledge of the performance and known problems of the different surveys, to resolve conflicts by excluding the data that were considered the least reliable.

The survivor numbers for some small year classes are not estimated but set at a small number to indicate that the year class is small, without attempting to quantify exactly how small. This is the case with the year classes 1995, 1996, 2000 and 2001. The oldest year classes (1988 and older, except 1983) were estimated by assuming a terminal fishing mortality taken from younger ages (option 4), with a scaling factor of 1.3, which appears as selection at age 14 in the parameter input (see the TASACS manual (Skagen and Skålevik 2012) Section 2.1.1. for detailed explanation). The survey information for these year classes is not used and is given zero weight.

## D. Short-Term Projection

## D1. The main assessment tool XSAM.

Model used: Stochastic forward projection using XSAM with management option table presenting average F -values for age 5-11 weighted over population numbers at the start of the year. The method is documented in Aanes 2016c. In 2018 at WKNSSHMSE (or was it WKNSSHREF?) this was changed to $5-12^{+}$. For short term forecast, the mean of the stochastic forecast is very similar to the corresponding deterministic forecast using mean values and is therefore used as basis for management options to be consistent with the implemented management plan. Prediction uncertainty is derived directly from 1000 realisations of stochastic projections defined by XSAM.

Software used: A prediction module has been developed for XSAM and is available on sharepoint.

Initial stock size: Input to the short-term projection is the stock number-at-age 3 and older (survivors) at the $1^{\text {st }}$ of January taken from the final assessment. For instance, if the last data year is 2008, the assessment provides the surviving stock numbers at the
$1^{\text {st }}$ of January 2009. Log recruits at age 2 are modelled as a random process $R_{t} \sim N\left(\mu_{R}, \sigma_{R}^{2}\right)$. Consequently, predictions of mean recruitment equal $\exp \left(\mu_{R}+0.5 \sigma_{R}^{2}\right)$ where $\mu_{R}$ is the mean recruitment at the log-scale, whereas the recruitment variability corresponds to the estimated variability in recruitment over the years included in the model fit.

Maturity: For the forecast it is recommended to use the maturity associated to 'normal' year classes unless the assessment indicate a strong year class (see B.2.4).

| AGE | $\mathbf{0}$ | $\mathbf{1}$ | $\mathbf{2}$ | $\mathbf{3}$ | $\mathbf{4}$ | $\mathbf{5}$ | $\mathbf{6}$ | $\mathbf{7}$ | $\mathbf{8}$ | $\mathbf{9}$ | $\mathbf{1 0}$ | $\mathbf{1 1}$ | $\mathbf{1 2}$ | $\mathbf{1 3}$ | $\mathbf{1 4}$ | $\mathbf{1 5}$ |
| :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- |
| normal <br> yc | 0 | 0 | 0 | 0 | 0.4 | 0.8 | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1 |
| strong <br> yc | 0 | 0 | 0 | 0 | 0.1 | 0.6 | 0.9 | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1 |

$\mathbf{F}$ and $\mathbf{M}$ before spawning: The SSB is calculated at the $1^{\text {st }}$ of January. Consequently the proportion of F and M before spawning is 0 .

Weight at age in the stock: for the intermediate year are the observed weights obtained from the winter survey (reference). For the other years the average of the last 3 years are used. Since 2008 the winter survey has stopped and weight at age data from commercial sampling in the same period and are used

Weight at age in the catch: is the average of the observed catch weights over the last three years.

Exploitation pattern: Predicted by XSAM. Estimates of F in the assessment year is available directly from the fitted model in the assessment year, while projected values follows exploitation pattern predicted the time series model for fishing mortality (see Annex C1 and Aanes 2016c for details). The selectivity component is modelled as a multivariate $\operatorname{AR}(1)$ process. Since this is a stationary process the mean predictions will be adjusted accordingly and gradually move towards to the estimated long term mean of selectivity.

Natural mortality: fixed values, the same as used in the assessment.
Intermediate year assumptions: catch constraint.
Stock recruitment model used: See Initial stock size above and Annex C1.2
Procedures used for splitting projected catches: not applicable.

## G. Biological Reference Points

## G.1. Precautionary and limit reference points: (Eydna, Erling)

The reference points were to be evaluated at WKPELA 2016. Due to time constraint only Blim was evaluated. The conclusion was that it should remain unchanged at 2.5 million tonnes. The reference points will be reviewed next time the management plan will be evaluated, which is expected to take place late autumn 2016.

The reference points for herring were considered by the Workshop on Limit and Target Reference Points (WKREF) held in Gdynia in 2007. Although it was the intention to review and update the biological basis of limit reference point taking into account the possible effects of species interactions and regime shifts, this has not been done because of lack of data. Instead, the breakpoint of a segmented regression applied to the stock recruitment plot was investigated. This breakpoint gives an indication at which SSB recruitment starts to decline and is a candidate for Blim. The breakpoint in the stock recruit data varied between $2-4$ million tonnes and seemed to be very sensitive to small changes in the estimates of the poor year classes (points near the origin of the $S / R$ plot) in assessments carried out in different years. WKREF could not explain the sensitivity and considered this behaviour of the model highly undesirable. WKREF decided to ask the Methods Working Group to investigate this observation further. Given this, the use of segmented regression technique to establish a limit biomass reference point for Norwegian spring-spawning herring was not considered appropriate until the observed methodological issue has been resolved.

The currently used values originate in an analysis carried out in 1998.

|  | ICES CONSIDERS THAT: | ICES PROPOSED THAT: |
| :--- | :--- | :--- |
| Precautionary Approach <br> reference points | Blim is 2.5 million t | $\mathrm{B}_{\mathrm{pa}}$ be set at 5.0 million t |
|  | Flim is not considered relevant <br> to this stock | $\mathrm{F}_{\mathrm{pa}}$ be set at $\mathrm{F}=0.15$ |
| Technical basis: |  |  |
| Blim: MBAL | $\mathrm{B}_{\mathrm{pa}}=\mathrm{Blim}^{*} \exp \left(0.4^{*} 1.645\right)$ (ICES Study Group 1998) |  |
| Flim: not relevant to this stock | $\mathrm{F}_{\mathrm{pa}}$ based on medium term simulations (ICES Study <br> Group 1998) |  |

The new assessment did not give different perceptions of the dynamics and levels of SSB and Fishing Mortality compared to the assessment which was the basis for establishing the reference points. Therefore there was no need to reconsider the reference points because of the new assessment method.

MSY reference points (included in 2010)

## HCS Simulation model analysis

HCS is a stochastic simulation model for studying different management scenarios. The parameterization of HCS for NSSH is described in a working document sent for WGWIDE in 2010 (WD, Skagen; the values for weights, natural mortality and initial N -values can be found in ICES 2009, WGWIDE Table 7.10.1.3, input to short-term prediction; see also Skagen 2010, WD WKFRAME). Two stock-recruitment relationships, Beverton-Holt and hockey stick, are explored:

Beverton-Holt: $R=a^{*} S S B /(S S B+b)$
Hockey stick: $\quad S>b: R=a$
$S<b: R=a^{*} S S B / b$
The stock-recruitment parameters are shown in Table 7.8.2. Parameters, and a plot of these together with the data are shown in Figure 7.8.2.srstoch. A plot of the data together with model output for Beverton-Holt function is show in Figure 7.8.2 srmodeldata, and the cumulative distribution of recruitment in data and model output is shown in Figure 7.8.2.cumdist. The long-term sustained yields with Beverton-Holt
recruitment function are shown in Figure 7.8.2.catch. A similar figure for hockey stick recruitment function can be found in Skagen 2010 (WD, Skagen).

In WKHERMAT in 2010 a new maturity ogive matrix for NSSH based on a back calculation methods was estimated (ICES 2010, WKHERMAT). This is used in the assessment in 2010. There appears to be a difference in the maturation ogive between strong and weak year classes such that strong year classes tend to mature at later age compared to weak year classes (Engelhart \& Heino 2004, ICES 2010, WKFRAME). However, the model used here currently allows only static maturity ogive, and in order to take into account the effect of variation in maturation of strong and weak year classes for MSY and $\mathrm{F}_{\text {msy }}$ we have run the analysis using the standard maturity ogive used in assessment the latest years, an ogive estimated for weak year classes and an ogive estimated for strong year classes (Table 7.8.2.modelparams). Furthermore, in year 2009 the selection pattern is different from the historical period, appearing more dome-shaped than the historical sigmoidal selection pattern (Table 7.8.2.modelparams). We have not been able to identify any reason why the selection pattern would have changed, as there have been no changes in gear or fishery in general. Nevertheless, we also studied the effect of possible change in selection pattern by using alternatively the historical (old) or the selection curve from 2009 (Table 7.8.2.modelparams).

The results of the simulation analysis suggest that the MSY, for all the scenarios and with both stock-recruitment functions, is within the same range: between 1 and 1.2 million tonnes (Figure 7.8.2.msyBH, 7.8.2.msyHS, and Table 7.8.2.results). Although the different scenarios result in MSY within the same range, the FMSY has more variation (Figure 7.8.2.fmsy and Table 7.8.2.results). When Beverton-Holt recruitment function is used, the risk of stock going below $B_{\lim }\left(2.5\right.$ million $t$.) and $B_{\text {trigger }}(4$ million t.) at FmSy are both very low, whereas with the Hockey stick recruitment function the risk of the stock falling below $\mathrm{B}_{\text {trigger }}$ at $\mathrm{Fmsy}^{\text {is relatively high (Table 7.8.2.results). }}$ Hockey stick recruitment function appears not to be very useful in modelling population dynamics, as the spawning stock size where MSY is reached is the same point where stock reproductive capacity starts decreasing (see also the discussion in the equilibrium analysis below). When Beverton-Holt recruitment function is used, unweighted Fmsy using the historical fishery selection pattern is 0.16 (for all maturity ogive scenarios), and adopting the 2009 selection pattern suggests of Fmsy 0.12 (for all maturity ogive scenarios). In NSSH management weighted F values are used, and the weighted values tend to be somewhat lower than unweighted values (Figure 7.8.2.fvalues). As we have no reason to believe that the selection pattern has really changed, we consider unweighted $\mathrm{F}_{\text {msy }}$ to be 0.16 . This unweighted F value is in close agreement with the reference values originating in an analysis carried out in 1998 (ICES 2008/ACOM 13), where a weighted $\mathrm{F}_{\mathrm{pa}}$ is defined as 0.150 .

## Equilibrium and YPR analyses

Deterministic and stochastic equilibrium analyses were carried out using the 'plotMSY' software (ICES 2010, WKFRAME) to determine candidate Fmsy values for the Norwegian spring-spawning herring stock. Stock-recruitment pairs from the period 1988-2009, as outputted from the most recent assessment of the stock, were used together with 5 -year averages of selectivity, weight and maturity-at-age (backcalculated ogive). Two stock recruit relationships were examined, Beverton and Holt and the ('smooth hockey stick' (segmented regression), and yield-per-recruit (YPR) analyses were also done. For the stochastic analyses, uncertainty (CVs) in the biologi-
cal and fishery parameters at age were used to create alternative fits to two stockrecruit relationships $(N=1000)$.

While the Beverton and Holt fit is reasonable under using the old maturity ogive to estimate SSB (results not shown), the majority of stochastic stock-recruit model fits fell out of the range of the deterministic fit to the data, and thus it can be concluded that the stock-recruit form is unclear and not suitable for the data and the level of uncertainty associated with the parameters. Using the new back-calculated maturity ogive, as has been decided by the working group for the assessment of this stock, results in an very poor Beverton and Holt fit (Figure 7.8.2.XXXsr), with an extremely steep slope at the origin and an asymptote at the geometric mean recruitment level. Given the lack of any clear patterns in the stock-recruit data, a hockey stick model fit, while uncertain around the origin, probably provides the most cautious fit to the data. For the hockey stick, the slope at the origin is the descending limb of the stockrecruit curve, which for this stock is relatively shallow, hence $\mathrm{F}_{\text {crash }}$ is low. The value for $B_{m s y}$ is at the breakpoint in the hockey stick, hence $F_{\text {msy }}$ is estimated to be the same as $\mathrm{F}_{\text {crash }}$ (Table 7.8.2. XXXmsy ). The uncertainty with regards to the slope at the origin makes this stock-recruitment function unsuitable as a basis for advice on $\mathrm{Fmsy}^{\text {m }}$. In such cases the slope is more useful as an indication of $\mathrm{F}_{\mathrm{pa}}$ or $\mathrm{F}_{\text {lim }}$.

Given the poor fits to stock recruitment functions, a yield-per-recruit analysis was conducted (Figure 7.8.2.XXXypr). The stochastic analysis shows a high degree of uncertainty and a very poorly defined $F_{\text {max. }}$. That both the hockey stick and per-recruit analysis suggests a high degree of uncertainty with regards to $\mathrm{F}_{\text {max }}$ could be down to the assumptions made about the uncertainties input into the analyses, though these assumptions are believed to be realistic given the information on the stock. This would preclude the use of $\mathrm{F}_{\max }$ as an $\mathrm{F}_{\text {msy }}$ proxy, although $\mathrm{F}_{0.1}$ may remain a viable, safer alternative. The YPR curve shows that F values in the range $0.125-0.15$ are likely to result in high long-term yields.

## Conclusions

In the equilibrium analysis, the structure of the stock and recruitment pairs as estimated from the most recent assessment does not lead to any clear definition of an optimum yield equilibrium fishing mortality level. Given this uncertainty it is more appropriate to select an $\mathrm{F}_{\text {msy }}$ proxy tested by a stochastic simulation model that takes into account the long-term trends in the stock biomass. The simulation model results presented in this report and in the stock annex provide a more appropriate method for the determining a viable long-term target, and the values from this analysis could be put forward as potential $\mathrm{F}_{\mathrm{msy}}$ targets. However, it should be noted that it is clear that the estimation of MSY reference points is very sensitive to the choice of stockrecruitment function and the approach chosen to estimate the reference points. This is in accordance with previous analyses by Skagen (WD 2010) and by WKFRAME (ICES 2010, WKFRAME).

The stochastic model uses unweighted F values, which have historically been found to be slightly lower than the unweighted values (Figure 7.8.2.fvalues). Therefore, a weighted $\mathrm{F}_{\text {msy }}$ of 0.15 corresponding to the unweighted $0.16 \mathrm{~F}_{\text {msy }}$ proxy from the simulation analyses is proposed for this stock. This is in agreement with the current simu-lation-tested management plan $F_{p a}$ level and should ensure high long-term yield with a low risk to the stock.

Index 1. The total number of herring larvae found during the cruise.

* Poor weather conditions and survey was late in April
** Only representative for the area $62-66^{\circ} \mathrm{N}$
***Likely that spawning was particularly early in 2009

Table B.3.7.1. Norwegian spring-spawning herring. Acoustic estimates from the coordinated ecosystem survey in Norwegian Sea and adjoining waters in July-August (IESSNS). Numbers in millions, biomass in million tonnes. StoX is used for 2016 while Beam is used for 2010-2015. Survey 9.
