# ICES COOPERATIVE RESEARCH REPORT 

## RAPPORT DES RECHERCHES COLLECTIVES

NO. 255

# Report of the ICES Advisory Committee on <br> Fishery Management, 2002 

Copenhagen, 21 May - 30 May 2002
Copenhagen, 9 October - 17 October 2002

PART 1
$\frac{\text { International Council for the Exploration of the Sea }}{\text { Conseil International pour l'Exploration de la Mer }}$

## TABLE OF CONTENTS

## PART 1 OF 3

Section ..... Page
Preface
Participants at Meetings, Spring and Autumn 2002
1 ICES ADVICE ..... i
1.1 The Form of ICES Advice. ..... i
2 INTRODUCTORY ITEMS ..... iv
2.1 Introduction ..... iv
2.2 Quality of Fishery Statistics .....  V
2.3 Catch projections for the current and following year ..... V
2.4 Mixed Fisheries ..... V
2.5 Structure of the Report .....  V
3 REVIEW OF STOCKS ..... 1
3.1 Stocks in the Northeast Arctic (Subareas I and II) ..... 1
3.1.1 Overview ..... 1
3.1.2 Cod in Subareas I and II .....  3
3.1.2.a North-East Arctic cod .....  3
3.1.2.b Norwegian coastal cod ..... 11
3.1.3 North-East Arctic Haddock (Subareas I and II) ..... 16
3.1.4 North-East Arctic saithe (Subareas I and II) ..... 23
3.1.5 Redfish in Subareas I and II ..... 29
3.1.5.a Sebastes mentella in Subareas I and II ..... 29
3.1.5.b Sebastes marinus in Subareas I and II. ..... 36
3.1.6 Greenland halibut in Subareas I and II ..... 42
3.1.7 Norwegian spring-spawning herring ..... 50
3.1.8 Barents Sea capelin (Subareas I and II, excluding Division IIa west of $5^{\circ} \mathrm{W}$ ) ..... 59
Shrimp (Pandalus borealis) ..... 64
3.2 Stocks in North-Western Areas (Division Va and Subareas XII and XIV) ..... 68
3.2.1 Overview ..... 68
3.2.2 Cod ..... 70
3.2.2.a Greenland cod (ICES Subarea XIV and NAFO Subarea 1) ..... 70
3.2.2.b Icelandic cod (Division Va) ..... 75
3.2.3 Icelandic haddock (Division Va) ..... 83
3.2.4 Icelandic saithe (Division Va) ..... 90
3.2.5 Greenland halibut in Subareas V and XIV ..... 96
3.2.6 Redfish in Subareas V, VI, XII and XIV ..... 104
3.2.6.a Overview ..... 104
3.2.6.b Sebastes marinus in Subareas V, VI, XII and XIV ..... 113
3.2.6.c Deep-sea Sebastes mentella on the continental shelf in Subareas V, VI and XIV ..... 118
3.2.6.d Pelagic fishery for Sebastes mentella in the Irminger Sea ..... 123
3.2.7 Icelandic summer-spawning herring (Division Va) ..... 129
3.2.8 Capelin in the Iceland-East Greenland-Jan Mayen area (Subareas V and XIV and Division IIa west of $5^{\circ} \mathrm{W}$ ) ..... 134
3.2.9 Answer to Special Request on Redfish ..... 138
3.3 Demersal stocks at the Faroe Islands (Division Vb) ..... 140
3.3.1 Overview ..... 140
3.3.2 Cod ..... 144
3.3.2.a Faroe Plateau cod (Subdivision $\mathrm{Vb}_{1}$ ) ..... 144
3.3.2.b Faroe Bank cod (Subdivision $\mathrm{Vb}_{2}$ ) ..... 150
3.3.3 Faroe haddock (Division Vb) ..... 154
3.3.4 Faroe saithe (Division Vb) ..... 160
3.4 Stocks in the Skagerrak and Kattegat (Division IIIa) ..... 166
3.4.1 Overview ..... 166
3.4.2 Cod in the Kattegat ..... 169
Section ..... Page
3.4.3 Whiting in Division IIIa (Skagerrak - Kattegat) ..... 176
3.4.4 Plaice in Division IIIa (Skagerrak - Kattegat) ..... 178
3.4.5 Sole in Division IIIa ..... 184
3.4.6 Pandalus borealis in Division IIIa and Division IVa East (Skagerrak and Norwegian Deeps) ..... 190
3.4.7 Herring in Subdivisions 22-24 and Division IIIa (spring spawners) ..... 196
3.4.8 Sprat in Division IIIa ..... 202
3.4.9 Sandeel in Division IIIa (Skagerrak - Kattegat) ..... 205
3.4.10 Anglerfish in Division IIIa (Skagerrak - Kattegat) ..... 206
3.4.11 Answer to special request from EC concerning TAC 2002 for Plaice in Division IIIa ..... 207
3.5 Stocks in the North Sea (Subarea IV) ..... 209
3.5.1 Overview ..... 209
3.5.2 Cod in Subarea IV (North Sea), Division VIId (Eastern Channel) and Division IIIa (Skagerrak) ..... 219
3.5.3 Haddock in Subarea IV (North Sea) and Division IIIa (Skagerrak - Kattegat) ..... 228
3.5.4 Whiting in Subarea IV (North Sea) and Division VIIId (Eastern Channel) ..... 238
3.5.5 Saithe in Subarea IV (North Sea), Division IIIa (Skagerrak) and Subarea VI
(West of Scotland and Rockall) ..... 245
3.5.6 Plaice in Subarea IV (North Sea) ..... 252
3.5.7 Sole in Subarea IV (North Sea) ..... 259
3.5.8 Herring in Subarea IV, Division VIId and Division IIIa (autumn spawners) ..... 267
3.5.9 Sprat in the North Sea (Subarea IV) ..... 281
3.5.10 Mackerel (North Sea component) ..... 285
3.5.11 North Sea horse mackerel (Trachurus trachurus) (Division IIIa (eastern part), Divisions IVb,c, VIId) ..... 285
3.5.12 Norway pout in Subarea IV (North Sea) and Division IIIa (Skagerrak - Kattegat) ..... 289
3.5.13 Sandeel ..... 296
3.5.13.a Sandeel in Subarea IV ..... 296
3.5.13.b Sandeel in the Shetland area ..... 304
3.5.14 Pandalus borealis ..... 306
3.5.14.a Pandalus borealis in Division IVa (Fladen Ground) ..... 306
3.5.15 Anglerfish in Subarea IV ..... 308
3.5.16 Answer to special request from EC concerning the status of Sea Bass in European waters ..... 309
3.5.17 Answer to special request from EC concerning review of study of Multiannual TAC arrangements for Flatfishes ..... 313

## TABLE OF CONTENTS

## PART 2 OF 3

Page3.5.18 Answer to requests from EC on rebuilding plans for cod and hake stocks ..... 316
3.5.18.a ICES is requested to investigate the performance and robustness of proposed multi-annual arrangements to set TACs (harvest control rules) as part of the stock rebuilding plans for North Sea cod. ..... 316
3.5.18b Answer to special request from EC on recovery plans for cod and hake stocks ..... 318
3.5.18.c Answer to special request from EC on recovery plans for cod and hake stocks ..... 320
3.5.19 Answer to EC Request on Overestimation in the Forecasting of Haddock and Whiting by-catch in the Industrial Fisheries ..... 324
3.6 Stocks in the Eastern Channel (Division VIId) ..... 326
3.6.1 Overview ..... 326
3.6.2 Sole in Division VIId (Eastern Channel) ..... 327
3.6.3 Plaice in Division VIId (Eastern Channel) ..... 332
3.7 Stocks in Subarea VI ..... 337
3.7.1 Overview. ..... 337
3.7.2 Cod ..... 339
3.7.2. $\quad$ Cod in Division VIa (West of Scotland) ..... 339
3.7.2.b Cod in Division VIb (Rockall) ..... 346
3.7.3 Haddock ..... 347
3.7.3.a Haddock in Division VIa (West of Scotland) ..... 347
3.7.3.b Haddock in Division VIb (Rockall) ..... 353
3.7.3.c Meeting to address Request from NEAFC to ICES on Rockall haddock ..... 358
3.7.4 Whiting ..... 359
3.7.4.a Whiting in Division VIa (West of Scotland) ..... 359
3.7.4.b Whiting in Division VIb (Rockall) ..... 365
3.7.5 Saithe in Subarea VI (West of Scotland and Rockall) ..... 366
3.7.6 Megrim in Subarea VI (West of Scotland and Rockall) ..... 366
3.7.7 Anglerfish in Subarea IV (North Sea) and Subarea VI (West of Scotland and Rockall) ..... 370
3.7.8 Herring West of Scotland ..... 378
3.7.8.a Herring in Division VIa (North) ..... 378
3.7.8.b Clyde herring (Division VIa) ..... 384
3.7.9 Norway pout in Division VIa (West of Scotland) ..... 386
3.7.10 Sandeel in Division VIa ..... 388
3.8 Stocks in the Irish Sea (Division VIIa) ..... 390
3.8.1 Overview ..... 390
3.8.2 Cod in Division VIIa (Irish Sea) ..... 392
3.8.3 Haddock in Division VIIa (Irish Sea) ..... 399
3.8.4 Whiting in Division VIIa (Irish Sea) ..... 402
3.8.5 Plaice in Division VIIa (Irish Sea) ..... 407
3.8.6 Sole in Division VIIa (Irish Sea) ..... 413
3.8.7 Irish Sea herring (Division VIIa) ..... 419
3.9 Stocks in the Celtic Sea (Divisions VIIf-k), Western Channel (Division VIIe) and northern parts of the Bay of Biscay (Divisions VIIIa,b-d, and e) ..... 422
3.9.1 Overview ..... 422
3.9.2 Cod in Divisions VIIe-k. ..... 424
3.9.3 Whiting in Divisions VIIe-k ..... 434
3.9.4 Celtic Sea plaice (Divisions VIIf and g) ..... 441
3.9.5 Sole in Divisions VIIf and g (Celtic Sea) ..... 448
3.9.6 Plaice in Division VIIe (Western Channel) ..... 454
3.9.7 Sole in Division VIIe (Western Channel) ..... 460
3.9.8 Sole in Divisions VIIIa,b (Bay of Biscay) ..... 468
3.9.9 Celtic Sea and Division VIIj herring ..... 478
3.9.9.a Response to the request from DG Fish concerning TACs for 2002 for Celtic Sea and Division VIIj herring ..... 481
3.9.10 Sprat in Divisions VIId,e ..... 483
3.9.11 Megrim (L. whiffiagonis) in Subarea VII and Divisions VIIIa,b,d ..... 485
3.9.12 Anglerfish in Divisions VIIb-k and VIIIa,b (L. piscatorius and L. budegassa) ..... 491
3.9.13 Response to the request from DG Fish concerning TACs for 2002 for Sole in Divisions VIIIa,b (Bay of Biscay) ..... 502
3.9.14 Plaice Southwest of Ireland (Division VIIh-k) ..... 503
3.9.15 Sole Southwest of Ireland (Division VIIh-k) ..... 504
3.10 Stocks in Divisions VIIb,c,h-k (West of Ireland) ..... 505
3.10.1 Overview ..... 505
3.10.2 Demersal Stocks ..... 506
3.10.2a Haddock in Divisions VIIb-k ..... 506
3.10.3 Herring in Divisions VIa (South) and VIIb,c ..... 509
3.10.4 Plaice West of Ireland (Division VIIb,c) ..... 512
3.10.5 Sole West of Ireland (Division VIIb, c) ..... 513
3.11 Stocks in the Iberian Region (Division VIIIc and Subareas IX and X) ..... 514
3.11.1 Overview ..... 514
3.11.2 Hake - Southern stock (Divisions VIIIc and IXa) ..... 516
3.11.3 Megrim (L. boscii and L. whiffiagonis) in Divisions VIIIc and IXa ..... 522
3.11.4 Anglerfish in Divisions VIIIc and IXa (L. piscatorius and L. budegassa) ..... 531
3.11.5 Mackerel in Divisions VIIIc and IXa (Southern component) ..... 537
3.11.6 Southern horse mackerel (Trachurus trachurus) (Divisions VIIIc and IXa) ..... 537
3.11.7 Sardine ..... 541
3.11.7.a Sardine in Divisions VIIIc and IXa ..... 541
3.11.8 Anchovy ..... 544
3.11.8.a Anchovy in Subarea VIII (Bay of Biscay) ..... 544
3.11.8.b Anchovy in Division IXa ..... 550
3.11.8.c Answer to EC request on harvest strategies for anchovy ..... 553
3.12 Widely Distributed and Migratory Stocks ..... 554
3.12.1 Overview ..... 554
3.12.2 Hake - Northern stock (Division IIIa, Subareas IV, VI and VII and Divisions VIIIa,b,d) ..... 555
3.12.3 Mackerel ..... 565
3.12.3.a Mackerel (combined Southern, Western and North Sea spawning components). ..... 565
3.12.3.b Response to the Government of the United Kingdom on the utility of the Western Mackerel Box ..... 579
3.12.4 Western horse mackerel (Trachurus trachurus) (Divisions IIa, IVa, Vb, VIa, VIIa-c, e-k, VIIIa,b,d,e) ..... 581
3.12.5 Blue whiting combined stock (Subareas I-IX, XII and XIV ..... 591
3.12.6 Response to Special Request from EC concerning the state of the Northern Hake stock and catch advice for 2002 ..... 600
3.12.7 Answer to Icelandic Request on Behalf of EU, Norway, Iceland, Greenland, and, Faroe Islands, and Russia on Blue Whiting ..... 602
3.12.8 Answer to request from NEAFC concerning blue whiting ..... 604

## TABLE OF CONTENTS

## PART 3 OF 3

Section ..... Page
3.13 Deep-water Fisheries Resources South of $63^{\circ} \mathrm{N}$ ..... 605
3.13.1 Overview ..... 605
3.13.2 Blue Ling (Molva dypterygia) ..... 624
3.13.3 Ling (Molva molva) ..... 633
3.13.4 Tusk (Brosme brosme) ..... 643
3.13.5 Roundnose grenadier (Coryphaenoides rupestris) ..... 652
3.13.6 Black scabbardfish (Aphanopus carbo) ..... 659
3.13.7 Greater silver smelt or argentine (Argentina silus) ..... 667
3.13.8 Orange Roughy (Hoplostethus atlanticus) ..... 672
3.13.9 Red seabream (Pagellus bogaraveo) ..... 679
3.13.10 Greater forkbeard (Phycis blennoides) ..... 683
3.13.11 Alfonsinos/Golden eye perch (Beryx spp.) ..... 687
3.13.12 Deepwater sharks ..... 692
3.14 Stocks in the Baltic ..... 698
3.14.1 Overview [Including overview of Salmon and Sea trout ..... 698
3.14.2 Nominal catches in the Baltic Area ..... 704
3.14.3 Herring in Subdivisions 22-24 and Division IIIa (spring spawners) ..... 710
3.14.4 Central Baltic Herring (Subdivisions 25-29 (including Gulf of Riga) and 32) ..... 716
3.14.4.a Herring in Subdivisions 25-29 (excluding Gulf of Riga herring) and 32 ..... 717
3.14.4.b Herring in the Gulf of Riga ..... 724
3.14.4.c Herring in Subdivisions 25-29 (including Gulf of Riga herring) and 3 ..... 730
3.14.4.d Comparison between the assessments. ..... 733
3.14.5 Herring in Subdivision 30, Bothnian Sea ..... 734
3.14.6 Herring in Subdivision 31, Bothnian Bay ..... 743
3.14.7 Sprat in Subdivisions 22-32 ..... 747
3.14.8 Cod in Subdivisions 22-24 (including Subdivision 23) ..... 757
3.14.9 Cod in Subdivisions 25-32 ..... 764
3.14.10 Flounder ..... 776
3.14.11 Plaice ..... 779
3.14.12 Dab ..... 782
3.14.13 Turbot ..... 784
3.14.14 Brill ..... 787
3.14.15 Salmon in the Main Basin and the Gulf of Bothnia (Subdivisions 22-31) ..... 789
3.14.16 Salmon in the Gulf of Finland (Subdivision 32) ..... 808
3.14.17 Sea Trout ..... 813
3.14.18 Answer to special request from IBSFC on selectivity in Cod trawls ..... 816
3.14.19 Answer to special request from IBSFC on pelagic fisheries ..... 822
3.14.20 Answer to special request from IBSFC on Research Plan for Central Baltic Herring ..... 824
3.14.21 Answer to special request from Finland concerning revision of the assessment of herring in Subdivision 30 ..... 826
3.15 Nephrops Stocks ..... 829
3.15.1 Overview of Nephrops stocks ..... 829
3.15.2 Nephrops in Divisions VIIIa,b (Management Area N) ..... 835
3.15.3 Nephrops in Division VIIIc (Management Area O) ..... 839
3.15.4 Nephrops in Division IXa (Management Area Q) ..... 843
4 ATLANTIC SALMON IN THE NORTH ATLANTIC AREA ..... 849
4.1 Catches of North Atlantic Salmon ..... 849
4.1.1 Nominal catches of salmon ..... 849
4.1.2 Catch and release ..... 849
4.1.3 Unreported catches of salmon ..... 849
4.1.4 Production of farmed and ranched salmon ..... 850
4.2 Review of the estimation of natural mortality (M) ..... 850
4.2.1 Methods for and estimates of natural mortality (M) at sea ..... 850
4.2.2 Effects of higher values of M on PFA models, conservation limits and catch advice ..... 852
4.3 Recent Research Developments and Information ..... 852
4.3.1 Incidence of infectious salmon anaemia virus in the USA ..... 852
4.3.2 Escaped farmed salmon of European ancestry in a Canadian River ..... 853
4.3.3 Changes in size selective mortality in migrating smolts ..... 853
4.3.4 Setting biological reference points for Atlantic salmon in the NEAC area using SR data from Index rivers ..... 853
4.3.5 Salmon stocks listed as endangered ..... 854
4.3.6 Biological reference points for North Atlantic salmon. ..... 854
4.3.7 Compilation of Tag Releases and Finclip Data by ICES Member Countries in 2001 ..... 855
5 ATLANTIC SALMON IN THE NORTH-EAST ATLANTIC COMMISSION AREA ..... 855
5.1 Events of the 2001 Fisheries and Status of Stocks ..... 855
5.1.1 Fishing in the Faroese area 2000/2001 commercial fishery ..... 855
5.1.2 Homewater fisheries in the NEAC area. ..... 855
5.2 Evaluation of the Effects on Stocks and Homewater Fisheries of Significant Management Measures Introduced Since 1991 ..... 856
5.2.1 Evaluation of the effects of management measures introduced in Faroes since 1991 ..... 856
5.2.2 Evaluation of the effects of management measures introduced in homewaters since 1991 ..... 856
5.3 Expected Abundance of Salmon in the North East Atlantic ..... 857
5.4 Development of Age-Specific Conservation limits. ..... 859
5.5 Catch Options or Alternative Management Advice ..... 859
5.6 Estimates of by-catch of post-smolts in pelagic fisheries in the Norwegian Sea ..... 860
5.7 Data deficiencies and research needs in the NEAC Area. ..... 861
6 ATLANTIC SALMON IN THE NORTH AMERICAN COMMISSION AREA ..... 861
6.1 Events of the 2001 fisheries and status of stocks. ..... 861
6.1.1 Fisheries in the NAC area. ..... 861
6.1.2 Status of stocks in the NAC area ..... 863
6.2 Effects on US and Canadian stocks and fisheries of the quota management and closure after 1991 in Canadian commercial salmon fisheries, with special emphasis on the Newfoundland stocks ..... 865
6.3 Age-specific stock conservation requirements ..... 865
6.4 Sensitivity analysis of the North American PFA analysis ..... 865
6.5 Catch options or alternative management advice with an assessment of risks. ..... 866
6.5.1 Catch option for 2002 fisheries on 2SW maturing salmon ..... 866
6.5.2 Catch option for 2003 fisheries on 2SW maturing salmon ..... 866
6.5.3 Data deficiencies, monitoring needs and research requirements ..... 866
7 ATLANTIC SALMON IN THE WEST GREENLAND COMMISSION AREA ..... 867
7.1 Events in the 2001 fisheries and status of stocks ..... 867
7.1.1 Fishery in the WGC area ..... 867
7.1.2 Evaluation of the ad hoc management system implemented in 2001 ..... 868
7.1.3 Status of stocks in the WGC area ..... 870
7.1.4 Changes in the continent of origin of salmon captured at West Greenland including changes in migration patterns ..... 871
7.2 Effects on European and North American stocks of the West Greenland management measures since 1993 ..... 872
7.3 Age-specific stock conservation limits for all stocks occurring in the WGC area ..... 873
7.4 Catch options or alternative management advice with an assessment of risks. ..... 873
7.4.1 Overview of provision of catch advice ..... 873
7.4.2 Development of catch options for 2002 ..... 875
7.4.3 Risk assessment of catch options ..... 875
7.5 Changes to the model used to provide catch advice ..... 877
7.6 Data deficiencies, monitoring needs and research requirements in the WGC area ..... 878
APPENDIX 1 ..... 936
APPENDIX 2 ..... 938
APPENDIX 3 ..... 939
8 EUROPEAN EEL ..... 940

## Preface

The ICES Advisory Committee for Fishery Management met twice in 2001, 21-30 May- and 9-17 October 2002. Both meetings were held at the ICES Headquarters, Palægade 2-4, Copenhagen. Attendance is listed on the following pages.

ACFM in its advice includes a description on how the Precautionary Approach have been interpreted in the ICES advice, see Form of Advice in the Introductory Chapter.

The reports are in response to requests from Management Commissions (EC, IBSFC, NEAFC, and NASCO) and from member countries. The management advice is presented stock by stock in Sections 3 to 8 where also the answers to special requests are given.

The requests from Management Commissions are now divided into two parts: recurrent advice that is specified by Memorandum of Understanding between the Management Commissions and ICES and Special Requests. Recurrent advice includes assessment of stock status and management advice for the more important stocks in the Northeast Atlantic. This advice is provided in the same form as used by ICES Advisory Committee for Fishery Management in recent years.

The special requests dealt with in this report included:

- From IBSFC on
- pelagic fisheries
- selectivity in Cod trawls
- research Plan for Central Baltic Herring
- From NEAFC and the coastal states on special problems related to the management of blue whiting.
- From EC on
- European sea bass.
- in-year review of the assessment of plaice in Division IIIa (Skagerrak-Kattegat), of Herring in the Celtic Sea, of Northern hake and of sole in the Bay of Biscay.
- rebuilding plans for cod and hake stocks
- overestimation in the Forecasting of Haddock and Whiting by-catch in the Industrial Fisheries
- concerning review of a study of Multiannual TAC arrangements for Flatfishes
- From Finland on in-year revision of the advice for Herring in Subdivision 30 (Gulf of Bothnia)
- From UK on the effects of the Mackerel box

## ADVISORY COMMITTEE ON FISHERY MANAGEMENT

PARTICIPANTS AT MEETING, SPRING 2002

| PARTICIPANTS | AFFILIATION | A | B |
| :---: | :---: | :---: | :---: |
| T. Jakobsen | Chair | X | X |
| C. O'Brien | Chair of Resource Management Committee | X | X |
| B. MacKenzie | Chair of Baltic Committee | X | X |
| J. Rice | Chair of Consultative Committee | X |  |
| W. Vanhee | Belgium | X | X |
| D. Rivard | Canada | X | X |
| S. Reeves | Denmark | X | X |
| T. Saat | Estonia | X | X |
| A. Leskelä | Finland | X | X |

A Plenary Sessions 14-17 October 2002
B Sub-Groups 9-12 October 2002

ICES recognises that "changes in fisheries systems are only slowly reversible, difficult to control, not well understood, and subject to change in the environment and human values" (FAO 1996). Therefore, ICES agrees that a precautionary approach should be applied to fishery management. Biological reference points, stated in terms of fishing mortality rates or biomass, are key concepts in implementing a precautionary approach. They are predefined benchmarks (limit reference points) that should be avoided to ensure that stocks and their exploitation remain within safe biological limits, and against which assessments should evaluate the status of the stock.

The concept of safe biological limits was introduced in ICES advice in 1981 and further developed in 1986 (Serchuk and Grainger, 1992). The aim of keeping stocks within 'safe biological limits' was described in the UN Agreement on Straddling Fish Stocks and Highly Migratory Stocks: a stock should be kept at a sustainable level by keeping it above a minimum biomass benchmark, and by keeping the fishing mortality below a maximum fishing rate benchmark. In 1998, ICES introduced precautionary biological reference points as the basis for its advice.

ICES provides advice on fishery management aimed at keeping the risk that the spawning biomass may fall below a minimum limit low. The minimum spawning stock biomass benchmark is described by the symbol $\mathbf{B}_{\text {lim }}$ (the biomass limit reference point). The value of $\mathbf{B}_{\text {lim }}$ is set on the basis of historical data, and chosen such that below it, there is a high risk that recruitment will 'be impaired' (seriously decline) and on average be significantly lower than at higher SSB. When information about the dependence of recruitment on SSB is absent or inconclusive, there will be a value of SSB, below which there is no historical record of recruitment. $\mathbf{B}_{\text {lim }}$ is then set close to this value to minimize the risk of the stock entering an area where stock dynamics is unknown.

Below $\mathbf{B}_{\text {lim }}$ there is a higher risk that the stock could 'collapse'. The meaning of 'collapse' is that the stock has reached a level where it suffers from severely reduced productivity. 'Collapse' does not mean that a stock is at high risk of biological extinction, but does mean that recovery to improved status is likely to be slow, and dependent of effective conservation measures.

The fishing mortality rate should not be higher than an upper limit $\mathbf{F}_{\text {lim }}$ which is the fishing mortality that, if maintained, will drive the stock to the biomass limit.

Spawning biomass and fishing mortality can only be estimated with uncertainty. Therefore, operational reference points are required to take account of this. To
keep the true risk low that spawning biomass falls below $\mathbf{B}_{\text {lim }}$, the estimated spawning biomass should in practice be kept above a higher level that allows for this uncertainty. Therefore, ICES applies a 'buffer zone' by setting a higher spawning biomass reference point $\mathbf{B}_{\mathbf{p a}}$ (the biomass precautionary approach reference point). ICES advises that when the spawning biomass is estimated to be below $\mathbf{B}_{\mathrm{p}}$, management action should be taken to increase the stock to above $\mathbf{B}_{\mathrm{pa}}$.

Similarly, to be certain that fishing mortality is below $\mathbf{F}_{\text {lim }}$, fishing mortality should in practice be kept below a lower level $\mathbf{F}_{\mathrm{pa}}$ that allows for uncertainty as well. ICES advises that when fishing mortality is estimated to be above $\mathbf{F}_{\mathbf{p a}}$, management action to reduce it to $\mathbf{F}_{\mathbf{p a}}$ should be taken. Such advice is given even if the spawning biomass is above $\mathbf{B}_{\mathrm{pa}}$ because fishing mortalities above $\mathbf{F}_{\mathrm{pa}}$ are not sustainable.

ICES gives advice on many stocks for which there is no analytical assessment and accordingly no basis for setting reference points as described above. Also in these cases ICES uses a precautionary approach, but alternative models are applied, with reference points referring to properties of the stock or fishery that can be estimated, for example catch per unit of effort instead of biomass.

The ICES advice is primarily risk-averse, i.e. it aims at reducing the risk of something undesirable happening to the stocks. Biological target reference points are also part of the Precautionary Approach, but setting targets for fisheries management involves socio-economic considerations. Therefore, ICES does not propose values for Target Reference Points, and at least until now Management Agencies have not identified management targets based on socio-economic benefits. Hence Target Reference Points have not been directly used in the advice. This means that even if the ICES advice is followed and therefore the stock should be protected from impaired productivity, exploitation of most stocks is likely to be sub-optimal, i.e. the longterm yield is lower than it could be.

Managers are invited to develop management strategies. ICES will comment on these and consider if they are consistent with the precautionary approach. If they are, ICES will frame the advice to be consistent with the adopted management targets.

## Framework for advice

When an assessment shows that the spawning biomass is below $\mathbf{B}_{\mathbf{p a}}$ ICES regards the stock as being 'outside safe biological limits', regardless of the fishing mortality rate, and ICES will provide advice to increase spawning biomass above $\mathbf{B}_{\mathbf{p a}}$, which may involve
reducing fishing mortality to levels below $\mathbf{F}_{\mathbf{p a}}$ possibly by a large amount cannot be achieved in the short-term, ICES will recommend the development of a rebuilding plan specifying measures to increase $\operatorname{SSB}$ above $\mathbf{B}_{\mathbf{p a}}$ in an appropriate time scale depending on the biological characteristics of the stock and other relevant factors.

When an assessment shows that the stock is above $\mathbf{B}_{\mathrm{pa}}$ but that the fishing mortality is above $\mathbf{F}_{\mathbf{p a}}$, the stock is 'harvested outside safe biological limits'. ICES will then recommend that the fishing mortality be reduced below $\mathbf{F}_{\mathbf{p a}}$ in the short term.

The ICES reference points in current use were set in 1998 using the stock and fishery data then available, as a provisional step in the implementation of the precautionary approach. In some cases, it has been necessary to change these reference point values as a result of changes in the data or the productivity of the stock, In order to improve consistency with the framework described above, and take advantage of new biological and fisheries information acquired on many stocks. ICES will review all these values in 2003.

### 2.1 Introduction

The Advisory Committee on Fishery Management (ACFM) consists of one designated fisheries scientist from each of the ICES member countries. The committee has an independently elected chair and the chairs of the scientific committees on Resource Management, Living Resource and Baltic are ex-officio members. The committee meets twice each year to review assessments and give advice on the status of fish stocks and to provide catch options for the coming year. The basis for the advice is reports of assessment working groups. These assessment reports are reviewed by sub-groups of ACFM members. Assessment Working Group chairs participate in these reviews.

The assessments presented in this report are carried out using the best catch data available to ICES. These data are not necessarily identical with the official statistics but, where appropriate, include estimates of unreported landings as well as corrections for misallocation of catches by area and species. Despite considerable effort exerted on this problem, there is no guarantee that all instances of misreporting were discovered. Often the catch data used by ICES are collated on a stock rather than an area basis, and so straightforward comparisons between these figures and the official statistics, which are provided on an area basis, are not appropriate.

In the assessments, ICES tries to estimate the total catch taken, including slipped catches, discards, landings which are not officially reported, and the composition of the industrial by-catches. These amounts of different species, which have to be included in the estimates of what has been taken from a given stock in order for the assessments to be correct, thus appear in the tables and figures in this report. These discards, slipped fish, unreported landings, and industrial by-catches vary considerably between different stocks and fisheries, being negligible in some cases and constituting important parts of the total removal from other stocks. In recent years more information on discards has been collected through observer programme.

The catch data used in the assessments are given in the "table" section of this report. In cases where there might be doubt, it has been indicated if discards, by-catches, and estimates of unreported landings are included in the assessments. Estimates of catches landed as by-catches, especially from the industrial fisheries, are included in the assessments wherever data allow it and are included in the catch options.

It should be noted that, in general, catches in the industrial fisheries of protected species above the minimum landing size which are sorted and landed for human consumption, are included in the estimates of human consumption landings, both in the catch input data
and in the projected catch options. Estimates of industrial by-catches cover, in most cases, that part of the by-catch which is used for reduction purposes.

In the past there have been problems associated with discrepancies between the official landing figures reported to ICES by member countries and corresponding catch data used by ICES. ICES recognises the need for a clear identification of the categories of the catch data used for assessments and whenever possible specifies the composition of the catch data used to estimate fishing mortalities. ICES also attempts to identify factors contributing to the total fishing mortality in the various stocks, e.g.:

- recorded landings,
- discards at sea,
- slipping of unwanted catches,
- losses due to burst nets etc.,
- unreported landings,
- catch reported as other species,
- catch reported as taken in other areas,
- catch taken as by-catch in other fisheries.

It is recognised that it may not always be possible to reveal the sources of the data. It is, however, indicated whether the data originate from sampling programmes, field observations, interviews, etc., in order to allow ICES and other interested parties to evaluate the quality of the data, and hence the basis for the assessment.

The overall responsibility for obtaining reliable, adequate and timely fisheries statistics, e.g. for publication in ICES Fisheries Statistics, rests with the national offices for fisheries statistics and fisheries research institutes. These agencies are also responsible for providing the catch data needed for assessments. They should ensure that catch statistics are collected on a gear basis and that the species composition of landings is determined in the case where landings are made unsorted by species.

### 2.2 Quality of Fishery Statistics

The quality of the assessments are directly linked to the quality of the fisheries data and ICES has expressed the greatest concern in past ACFM advice over the quality of catch and effort data from most of the important fisheries in the ICES area. ICES stressed that the immediate consequences of this are that ICES will be unable to provide reliable estimates of current stock sizes and forecasts that have been used to set TACs. Trends in stock size and the overall status of the stock can sometimes be evaluated from research vessel surveys, but such information alone cannot be used to give the shortterm TAC advice usually required.

### 2.3 Catch projections for the current and following year

The Catch Option table is a basis part of the ICES advice and these catch options are based on assumptions about the total catch in the current or intermediate year. This value has been debated, especially when it is larger than the total TAC for the given year.

The catch assumption is a projection of trends in the fisheries and the projection is based on case specific conditions. In many cases, ICES considers two alternatives: 1) to assume that the catch will be equal to the TAC (a TAC constraint) or 2 ) to assume that the fishing mortality, F , will continue equal to that of previous year (a $\mathrm{F}_{\text {status quo }}$ constraint). In some cases the stock unit used by ICES does not match the TAC area used by the management agencies. In those cases it can be difficult to establish how the TAC will restrict the catch from the stock and often the F status quo is used.

Calculation of the best estimate of the status quo fishing mortality by age varies between stocks. The form of the estimate depends of temporal trends in the fishing mortalities and in the exploitation pattern. Also the variance of the estimate in individual years needs to be considered. In several cases a mean over the last three years are used sometimes scaled to the level of fishing mortality in the most recent year.

### 2.4 Answer to special request from EC on Mixed Fisheries

EC DG Fish has requested scientific advice on mixed fisheries for 2002 as follows:

1. The relevant ICES assessment working groups should be asked, as soon as possible, to propose appropriate definitions of fishing fleets, as far as possible, as operationally distinct and functionally homogenous units. When considering such definitions, account should be taken of the definitions of fleet sectors that exist in Community legislation (particularly Regulation 850/98 and its amendments) and these sectors should be used where possible and appropriate. For the fleet sectors defined as above, estimate landings (and discards where available), disaggregated by species, fleet, and ICES division (or subdivision where possible), for the years 1999, 2000 and 2001.
2. These data should be provided to the Commission services for the attention of STECF as soon as possible after the meetings of each assessment working group. Where there are gaps in the available information, ICES should draw the attention of STECF to these deficiencies.
3. SGRST/STECF will, after the annual advice has been provided by ACFM, be asked to use the aforementioned data to make fishery-based calculations and forecasts corresponding to some scenarios based on ACFM advice.

## ICES Comments:

Information on species composition of the catch by fisheries has been reviewed for stocks in the North Sea and is provided in the Overview section for that area (Table 3.5.1.3a). This served to identify the fleets for which landings appear as a mixture of various species. This information is consistent with the common knowledge that these fleets often operate on a species mix, e.g. cod, haddock, and whiting for some or plaice, sole, and cod for others.

It was noted that information is available at the set-byset level and that such a level of detail may reveal more on the mixtures encountered when fishing these stocks. More detailed information is being assembled for these stocks, as well as for stocks in other areas, and will be considered by a Subgroup of STECF shortly as indicated in the letter from DG Fish. Also, the ACFM Study Group on the Development of Fishery-based Forecasts (SGDFF) will meet in early 2003 to review approaches to the operational definition of fishery based on individual voyage data within various groups, define fishery-based data requirements for multi-fishery, mixed-species forecasts, and agree on data formats for the compilation of national datasets into international fishery-based datasets. It has not been possible to compile similar data for other areas where fisheries occur that are similar to the North Sea mixed demersal fisheries.

The relevant ICES Working Groups have been asked to consider these problems at the next round of the assessments in 2003.

### 2.5 Structure of the Report

Information and advice are provided on an area basis. Thus, all stocks belonging to a given area are placed in a separate section, together with an overview of the state of the stocks and fisheries in that area. Special requests from Commissions or member countries of ICES are placed in the section dealing with the respective area and stock.

Exceptions to this structure are that the report to the North Atlantic Salmon Conservation Organization and reports on Nephrops (Section 3.14) and on European eel (Section 3.16) are provided as separate sections. Section 3.15 provides some preliminary information on the status of European Sea bass stocks.

### 3.1 Stocks in the Northeast Arctic (Subareas I and II)

### 3.1.1 Overview

## Major stocks and landings

The total landings of fish and invertebrates in this area in 2001 were in the order of 2.7 million $t$. These catches were taken from a variety of demersal and pelagic stocks.

The major demersal stocks in the Northeast Arctic include cod, haddock, saithe, and northern shrimp. In addition, redfish, Greenland halibut, and flatfishes (e.g., long rough dab, plaice) are common on the shelf and at the continental slope, with ling and tusk found also at the slope and in deeper waters. In 2001, landings of 0.7 million $t$ were taken from the stocks of cod, haddock, saithe, redfish, and Greenland halibut. An additional catch of about 100000 t was taken from demersal stocks, including crustaceans, not assessed at present.

The major pelagic stocks are capelin, herring, and polar cod. The highly migratory species blue whiting and mackerel extend their feeding migrations into this region. The international fishery for herring in 2001 was 770000 t . The capelin fishery in the Barents Sea in 2001 was 406000 t . In addition, there were landings from Subareas I and II of 592000 t blue whiting in 2001 (including Divisions Va and XIVa-b) and 92000 t mackerel in 2000 (including Division Vb).

Invertebrate species of krill, copepods, and amphipods are considered to be important food resources for the fish stocks in this area. Marine mammals play an important role as predators on fish. Several other species of fish and invertebrates are found in the area. Species with relatively small landings include salmon, halibut, hake, pollack, whiting, Norway pout, anglerfish, wolffish, lumpsucker, argentines, grenadiers, flatfishes, horse mackerel, dogfishes, skates, crustaceans, and molluscs.

## Fleets and fisheries

The fleets operating in this area are:

1. Factory and freezer trawlers operating in the whole area all year round targeting mainly cod, haddock and saithe and taking other species as by-catch. The number of these vessels has been stable in recent years, at a lower level than previously.
2. Fresh fish trawlers operating in Subarea I and Division IIa all year round targeting mainly cod and haddock, taking other species as by-catch. The
number of these vessels has been reduced in recent years.
3. Freezer trawlers operating in Subarea I and Division IIb fishing shrimp. The number of these vessels has been stable.
4. Large purse seiners and pelagic trawlers targeting herring, mackerel, blue whiting, capelin, and polar cod in seasonal fisheries in this region. These vessels fish some of the same species in other areas as well.
5. Small fresh fish trawlers targeting shrimp and capelin in near-coast areas in Subarea I. The size of this fleet has decreased in recent years.
6. A fleet of vessels using conventional gears (gillnet, longline, handline, and Danish seine) mainly in near-shore fisheries targeting various demersal species all around the year. This fleet, together with fleets 7 and 8, accounts for approximately $30 \%$ of landings of demersal stocks. This share is maintained by quota allocation. When vessels in this fleet are modernised or replaced, there is a trend towards medium-sized (app. 15-20 m) multi-gear vessels with crews of $3-5$.
7. Small purse seiners targeting saithe in coastal waters in a seasonal fishery, to a large extent vessels belonging to the group using conventional gears.
8. Longliners operating offshore targeting non TACrestricted species, mainly ling, blue ling and tusk. These vessels are generally larger than those in the coastal fisheries and use technologically advanced auto-line systems.

## Management measures

The fisheries in Subareas I and II are managed by TAC constraints for the main stocks and by allocation of TAC shares amongst states with established fishing interests. These Subareas consist mainly of waters within EEZs but also contain some waters outside EEZs.

For the main species the fisheries in the EEZs are regulated by quotas at a variety of scales (vessels, fleets, species, season). Management measures also regulate minimum landing size, mesh size, and use of sorting
grids. Since January 1997 use of sorting grids in the trawl fisheries has been mandatory for most of the Barents Sea and Svalbard area. Minimum landing size is also a minimum catching size, implying that vessels have to avoid fishing grounds with small-sized fish. Discarding is prohibited in some EEZs. Time and area closures may be implemented to protect small fish.

Compilation of effort data relevant to the different species is difficult when the fisheries are regulated by vessel quotas. In some cases the effort targeted at the main species, e.g., cod, may be calculated, but it is almost impossible to calculate effort for non-target species.

## Current status in the Northeast Arctic

The recent developments in the stocks of cod, haddock, saithe, Greenland halibut, redfishes, herring, and capelin are summarised in the following.

The stocks of cod and Sebastes mentella are outside safe biological limits, haddock is harvested outside safe biological limits, while saithe is within safe biological limits.

The status of the Greenland halibut stock is not precisely known. SSB shows signs of improvement but is still among the lowest in the time-series, and recruitment in recent years is also estimated to be well below the historic average.

The available information on Sebastes marinus is insufficient to assess the stock properly, but there are strong signs in the surveys of reduced recruitment, and both the coastal survey and commercial CPUE indicate a decrease for larger fish.

The capelin stock is within safe biological limits although the recent stock increase has culminated and the stock has decreased slightly in the last year.

Norwegian spring-spawning herring is harvested at or slightly above safe biological limits. The spawning stock is declining, but is still considered to be within safe biological limits.

Considerable effort has been devoted to investigating multispecies interactions. Some of these investigations have reached the stage where quantitative results are available for use in assessments. Growth of cod depends on availability of prey such as capelin, and variability in cod growth has had major impacts on the cod fishery. Cod are able to compensate only partially for low capelin abundance, by switching to other prey species. Low capelin abundance has caused high cannibalism on juvenile cod, and increased predation in impacts on other prey species, e.g. juvenile herring and haddock. Herring predation on capelin larvae is believed to be partially responsible for the recruitment failure of capelin when young herring are abundant in the Barents Sea.

The annual consumption of herring and capelin by marine mammals (particularly harp seals and minke whales) has been estimated to be in the order of 5 million $t$. The composition and distribution of species in the Barents Sea depend considerably on the position of the polar front which separates warm and salty Atlantic waters from colder and fresher waters of arctic origin. Variation in the recruitment of some species including cod and herring has been associated with changes in the influx of Atlantic waters into the Barents Sea.

### 3.1.2 Cod in Subareas I and II

### 3.1.2.a Northeast Arctic cod

State of stock/fishery: The stock is outside safe biological limits. Fishing mortality in the last four years has been among the highest observed and well above $\mathbf{F}_{\mathrm{pa}}$, even above $\mathbf{F}_{\text {lim }}$, and is not sustainable. SSB has been below $\mathbf{B}_{\mathrm{pa}}$ since 1998. Surveys indicate below average 1999 and 2000 year classes and a very poor 2001 year class.

Management objectives: In recent years, the advice has been to reduce fishing mortality below $\mathbf{F}_{\mathrm{pa}}(=0.42)$ and to keep the spawning stock above 500000 t , which was considered to be the minimum value required to have a low probability of poor recruitment. This approach was incorporated into a management objective in the years 1997-1999. The latest agreement in the Joint RussianNorwegian Fisheries Commission sets a TAC of 435000 t (including 40000 t Norwegian Coastal cod) for 2001, 2002, and 2003. The intention is that this TAC could be revised either if the stock situation is more serious than known at the time of the
agreement, or if the stock is assessed to be within safe biological limits. ICES considers that TACs under this agreement are well above those that would correspond to the application of the precautionary approach.

Precautionary Approach reference points: The biological information on historic stock and recruitment sizes has been revised. These revisions have altered some of the historic values substantially, with two consequences. Spawning biomasses associated with some historic recruitment are now estimated to have been lower and current reference points may be revised. ACFM in May 2001 and the external peer-review in October 2001 considered that more detailed analyses were required as a basis for new reference points and recommended that old values be used until such studies were completed. This work should be undertaken by a dedicated Study Group that will meet before the next AFWG meeting in 2003, building upon the work of the most recent AFWG.

Reference points (1998)

| ICES considers that: | ICES proposes that: |
| :--- | :--- |
| $\mathbf{B}_{\text {lim }}$ is 112000 t | $\mathbf{B}_{\mathrm{pa}}$ is set at 500000 t , the value below which the <br> probability of below average year classes increases |
| $\mathbf{F}_{\text {lim }}$ is 0.70 | $\mathbf{F}_{\mathrm{pa}}$ be set at 0.42. This value is considered to have a $95 \%$ <br> probability of avoiding the $\mathbf{F}_{\text {lim }}$ |

Technical Basis:

| $\mathbf{B}_{\text {lim }}=\mathbf{B}_{\text {loss }}$ | $\mathbf{B}_{\mathrm{pa}}=$ examination of stock-recruit plot |
| :--- | :--- |
| $\mathbf{F}_{\text {lim }}=$ Median value of $\mathbf{F}_{\text {loss }}$ | $\mathbf{F}_{\mathrm{pa}}=5^{\text {th }}$ percentile of $\mathbf{F}_{\text {loss }}=\mathbf{F}_{\text {lim }} \times 0.6$ |

Advice on management: In order to harvest the stock within safe biological limits, ICES recommends a considerable reduction in fishing mortality to below $F_{p a}(0.42)$. This corresponds to catches in 2003 of less than 305000 t .

Relevant factors to be considered in management: The TAC for 2002 was set considerably higher than recommended by ICES. The pre-agreed TAC for 2003 (435000 t, including 40000 t of Norwegian coastal cod) is expected to result in a fishing mortality well above $\mathbf{F}_{\mathrm{p} \text { a }}$.

Evidence of under-reporting of catches in recent years is accumulating. Both discards and unreported landings will reduce the effect of management measures and it is important that management agencies ensure that all catches are counted against the TAC regulations.

The majority of the spawning stock comprises first time spawners. Evidence has shown that the eggs and larvae of first-time spawners are less viable than those of other mature fish, but also that the overall spawning period is reduced when the spawning stock consists of fewer age groups. Both these factors can reduce the reproductive potential of the stock for the same biomass.

## Catch forecast for 2003

Basis: $\mathrm{F}(2002)=\mathrm{F}_{\mathrm{sq}}=0.84 ;$ Catch $=523 ; \operatorname{SSB}(2003)=$ 429.

| F | Basis | Landings <br> 2003 | SSB <br> 2004 |
| :--- | :--- | :---: | :---: |
| 0.00 | 0 | 0 | 850 |
| 0.17 | $0.2^{*} \mathbf{F}_{\mathrm{sq}}$ | 134 | 740 |
| 0.34 | $0.4^{*} \mathbf{F}_{\mathrm{sq}}$ | 251 | 647 |
| 0.42 | $\mathbf{F}_{\mathrm{pq}}\left(=0.5 * \mathbf{F}_{\mathrm{sq}}\right)$ | 305 | 605 |
| 0.51 | $0.6^{*} \mathbf{F}_{\mathrm{sq}}$ | 355 | 566 |
| 0.63 | Catch $2003=$ Catch 2 <br> $001\left(0.75 * \mathbf{F}_{\mathrm{sq}}\right)$ | $425^{*}$ | 512 |
| 0.84 | $1.0^{*} \mathbf{F}_{\mathrm{sq}}$ | 529 | 435 |

*Corresponding to expected landings of 426000 t created by the pre-agreed quota of 435000 t Northeast Arctic cod + Norwegian Coastal cod.
Weights in ' 000 t .
Shaded scenarios considered inconsistent with the precautionary approach.

Comparison with previous assessment and advice: In previous assessments, fishing mortality $\mathrm{F}_{(5-10)}$ in the most recent years was often underestimated and stock numbers overestimated in the annual assessments of the stock. The current assessment does not present such retrospective patterns, and it is inferred that this over/underestimation is less evident for this assessment. The estimated stock numbers in 2001 are close to last years assessment, while the estimate for F in 2001 ( 0.84 ) is higher than expected from a TAC-constrained forecast in last years assessment ( 0.66 ), but lower than assumed by the F status quo forecast ( 0.91 ). The expectation of future SSBs is much higher than what was projected in 2001. This is mainly due to a much higher maturation rate for ages $6-8$ observed in surveys in the autumn 2001 and in the winter of 2002. The projections are based on the assumption that high maturation rates prevail in 2003 and 2004. This assumption is supported by historical experience.

Elaboration and special comment: Changes in growth, maturity, and cannibalism are linked to abundance of capelin. Capelin abundance has increased since 1997 and is expected to stay at a high level in 2002. A considerable reduction in cod cannibalism has been observed since 1996, while a small increase in mean weight at age is observed since 2000. Annual variation in growth and maturity can be substantial for this stock.

The fishery for Northeast Arctic cod is conducted both by an international trawler fleet operating in offshore waters, and by vessels using gillnets, longlines, handlines, and Danish seine operating both offshore and in the coastal areas. Quotas were introduced in the trawl fishery in 1978 and for the fisheries with conventional gears in 1989. In addition to quotas the fisheries are regulated by mesh size limitations (including sorting grids), a minimum catching size, a maximum by-catch of undersized fish, maximum by-catch of non-target species, closure of areas with high densities of juveniles, and by seasonal and area restrictions. Since January 1997 sorting grids have been mandatory for the trawl fisheries in most of the Barents Sea and Svalbard area. The fisheries are controlled by inspections of the trawler fleet at sea, by a requirement of reporting to catch control points when entering and leaving the EEZs, and by inspections for all fishing vessels when landing the fish. Keeping a detailed fishing log-book on board is mandatory for most vessels, and large parts of the fleet report to the authorities on a daily basis. There is some evidence that the present catch control and reporting systems are not sufficient to prevent underreporting of catches.

The assessment is based on analysis of catch-at-age data, using one commercial CPUE series and three survey series. Estimates of cannibalism are included in the natural mortality. Alternative assessment methods (Fleksibest) are in development.

Source of information: Report of the Arctic Fisheries Working Group, 16 - 25 April 2002 (ICES CM 2002/ACFM:18).

Yield and spawning biomass per Recruit F-reference points:

|  | Fish Mort <br> Ages 5-10 | Yield/R | SSB/R |
| :--- | :---: | :---: | :---: |
| Average Current | 0.842 | 1.083 | 0.744 |
| $\mathbf{F}_{\max }$ | 0.251 | 1.261 | 3.907 |
| $\mathbf{F}_{0.1}$ | 0.128 | 1.158 | 7.165 |

### 3.1.2.b Norwegian Coastal cod

State of stock/exploitation: At present, the SSB is the lowest observed in the time-series extending back to 1984. The stock has declined continuously since 1994 , and fishing mortality increased from 1991 to 1999; since then it has stabilised. Recruitment in recent years has been well below average. The landings increased steadily from 1991 and up to 1997; since then they have decreased. The assessment reflects the general trends in the development of the stock, though it is not regarded as accurate.

Management objectives: There are no explicit management objectives for this stock. Management objectives should be defined, taking the status of the stock into consideration. In particular considerations should be given to the possibility of managing Norwegian Coastal cod separately from Northeast Arctic cod.

Precautionary Approach reference points: No precautionary reference points have been proposed for this stock, but candidate reference points are under investigation.

Advice on management: ICES recommends a considerable reduction in fishing mortality to allow the SSB to rebuild.

Relevant factors to be considered in management: The TAC for 2002 was set considerably higher than recommended by ICES. Due to the low stock size, the agreed TAC for 2002 ( 40000 t ) is not expected to be taken. The SSB is historical low, and the year classes recruiting to the SSB over the next few years seem to be well below average. Unless fishing mortality is reduced considerably, a further decrease in the total stock biomass and SSB is expected. Management measures should be implemented to ensure that catches, in particular, are reduced in areas where, and in seasons when, the proportion of Norwegian Coastal cod in the catch is large compared to Northeast Arctic cod.

Norwegian Coastal cod is managed as part of the Norwegian Northeast Arctic cod fishery. An expected yield of 40000 t from the Coastal cod has been added annually since the mid-1970s to the quota for Northeast Arctic cod. If this practice is followed in 2003 and the quota is taken, both the stocks (Norwegian Coastal cod and Northeast Arctic cod) will continue to be overexploited. If Norwegian Coastal cod could be managed independently of Northeast Arctic cod, ACFM for 2002 would advise that the fishing mortality be reduced by at least $80 \%$ compared to F in 2001 in order to halt the decline in the spawning stock.

## Catch forecast for 2003:

Basis: $\mathrm{F}(2002)=\mathbf{F}_{\mathrm{sq}}=0.48$; Landings(2002) $=27$; $\mathrm{SSB}(2003)=45$.

| $\mathrm{F}(2003$ <br> onwards) | Basis | Landings <br> $(2003)$ | SSB (2004) |
| :---: | :---: | :---: | :---: |
| 0 | $0 * \mathbf{F}_{\mathrm{sq}}$ | 0 | 60 |
| 0.10 | $0.2 * \mathbf{F}_{\mathrm{sq}}$ | 5 | 54 |
| 0.19 | $0.4 * \mathbf{F}_{\mathrm{sq}}$ | 10 | 49 |
| 0.27 | $0.56 * \mathbf{F}_{\mathrm{sq}}$ <br> $=\mathbf{F}_{\mathrm{pa}}$ | 13 | 45 |
| 0.29 | $0.6 * \mathbf{F}_{\mathrm{sq}}$ | 14 | 44 |
| 0.38 | $0.8 * \mathbf{F}_{\mathrm{sq}}$ | 18 | 40 |
| 0.48 | $1.0 * \mathbf{F}_{\mathrm{sq}}$ | 22 | 36 |

Weights in ' 000 t .
Comparison with previous assessment and advice: The calculated fishing mortality $\mathrm{F}_{4-7}$ and SSB in 2000 are almost the same for last year's assessment and this year's assessment (F- 0.49, 0.46; SSB- 65000 t, 67000 t). The recruitment in 2000 is approximately $30 \%$ reduced in this year's assessment ( 21.7 mill, 14.6 mill). The change in catchability dependent on stock for age 2 causes most of the difference in recruitment. This is also more in accordance with the survey data. Last year ICES advised a $65 \%$ reduction in fishing mortality if this stock could be managed independently from Northeast Arctic cod to halt the decline in SSB. Due to the continued decline in SSB a greater reduction in fishing mortality is advised this year.

| Assess <br> ment <br> year | $\mathrm{F}_{4-7}$ <br> year <br> 2000 | SSB <br> year <br> 2000 | Total stock <br> biomass year <br> 2000 | Recruits <br> age 2 year <br> 2000 |
| :--- | :---: | :---: | :---: | :---: |
| 2001 | 0.49 | 65 | 121 | 22 |
| 2002 | 0.46 | 67 | 121 | 15 |

Elaboration and special comment: The fishery for Norwegian Coastal cod is part of a directed fishery on cod in Norway using a variety of traditional gears, including trawl, and has been conducted for several decades. The catches include both Northeast Arctic cod and Norwegian Coastal cod in some areas and in some periods of the year. In Finnmark 43 likely spawning areas for Norwegian Coastal cod have been identified. Among these 24 are closed for Danish seine fishery in the first five months of the year. Trawl fisheries for roundfish are not allowed at any time of the year within 4 nautical miles of the coast.

The method of catch separation by otolith pattern has been used in recent years to estimate landings from the Norwegian Coastal cod stock. The landings data are not considered to be estimated precisely.

The stock was assessed by XSA using commercial catch-at-age data and an acoustic survey series. The catch data used in analysis go back to 1984 and the survey series to 1995.

### 3.1.3 Northeast Arctic haddock (Subareas I and II)

State of stock/exploitation: The stock is outside safe biological limits. Fishing mortality in 2001 is estimated to be well above the proposed $\mathbf{F}_{\mathrm{pa}}$ and has been above $\mathbf{F}_{\text {lim }}$ in 1997-1999 and around $\mathbf{F}_{\text {lim }}$ in 2000-2001. The SSB in 2002 is estimated to be below ( 72000 t ) the $\mathbf{B}_{\mathrm{pa}}$ of 80000 t , but is expected to increase to above $\mathbf{B}_{\mathrm{pa}}$ in the shortterm. The 1999-2000 year classes are indicated to be above average.

Management objectives: There have been no management objectives other than managing the stock within safe biological limits. However, for any management objectives to be consistent with the precautionary approach, their aim should be to reduce or maintain F below $\mathbf{F}_{\mathrm{pa}}$ and to increase or maintain spawning stock biomass above $\mathbf{B}_{\mathrm{pa}}$.

Precautionary Approach reference points (Unchanged since 2000):

| ICES considers that: | ICES proposes that: |
| :--- | :--- |
| $\mathbf{B}_{\text {lim }}$ is $50000 t$ the SSB below which only poor year <br> classes have been observed. | $\mathbf{B}_{\mathrm{pa}}$ be set at 80000 t , which is considered to be the <br> minimum SSB required to provide a 95\% probability of <br> maintaining SSB above $\mathbf{B}_{\text {lim }}$, taking into account the <br> uncertainty in the assessments and stock dynamics. |
| $\mathbf{F}_{\text {lim }}$ is 0.49, the fishing mortality associated with <br> potential stock collapse. | $\mathbf{F}_{\mathrm{pa}}$ is set at 0.35. This value is considered to have a high <br> probability of keeping F below $\mathbf{F}_{\text {lim }}$. |

## Technical Basis:

| $\mathbf{B}_{\text {lim }}:$ only poor recruitment has been observed from 4 <br> years of SSB $<50000 \mathrm{t}$ and all moderate or large year <br> classes have been produced at higher SSB. | $\mathbf{B}_{\mathrm{pa}}=\mathbf{B}_{\mathrm{lim}} * 1.67$. |
| :--- | :--- |
| $\mathbf{F}_{\text {lim }}=$ median value of $\mathbf{F}_{\text {loss. }}$ | $\mathbf{F}_{\mathrm{pa}}=\mathbf{F}_{\text {med. }}$ The stock has sustained higher fishing <br> mortality for most of the period after 1950 without <br> collapsing; however, low SSB has often resulted. |

Advice on management: ICES recommends that fishing mortality be reduced to below $\mathrm{F}_{\mathrm{pa}}=0.35$, corresponding to catches of less than 101000 t in 2003.

Comparison with previous assessment and advice: Mean fishing mortality in 2001 (0.46) is estimated as the same value used as status quo fishing mortality last year. Last year's assessment predicted the SSB in 2002 to be 76000 t , compared to 72000 t in the current assessment.

Relevant factors to be considered in management: A substantial portion of the NEA haddock catch is taken as by-catch in the NEA cod fishery.

Catch forecast for 2003:
Basis: $\mathrm{F}(2002)=\mathbf{F}_{\mathrm{sq}}=\mathrm{F}(99-01)=0.52$; landings $=100$; $\operatorname{SSB}(2003)=100$.

| F (2003) | Basis | Catch <br> $(2003)$ | Landings <br> $(2003)$ | SSB <br> $(2004)$ |
| :--- | :--- | :---: | :---: | :---: |
| 0.00 | $0.00 * \mathbf{F}_{\mathrm{sq}}$ |  | 0 | 194 |
| 0.10 | $0.20 * \mathbf{F}_{\mathrm{sq}}$ |  | 33 | 176 |
| 0.21 | $0.40 * \mathbf{F}_{\mathrm{sq}}$ |  | 63 | 160 |
| 0.31 | $0.60 * \mathbf{F}_{\mathrm{sq}}$ |  | 91 | 146 |
| 0.35 | $0.67 * \mathbf{F}_{\mathrm{sq}}$ <br> $\left(\mathbf{F}_{\mathrm{pa}}\right)$ | 101 | 141 |  |
| 0.42 | $0.80 * \mathbf{F}_{\mathrm{sq}}$ |  | 116 | 133 |
| 0.52 | $\mathbf{F}_{\mathrm{sq}}$ |  | 139 | 122 |

Weights in ' 000 t .
Shaded scenarios considered inconsistent with the precautionary approach.

Elaboration and special comment: The above average year classes are expected to enter the fishable stock in 2002, and the SSB and total biomass is expected to increase.

The results of the forecast are also sensitive to the estimates of variable maturity and natural mortality rates. The latter will very much depend on the development of the capelin and cod stocks in the near future.

Fishing mortality has been above $\mathbf{F}_{\text {lim }}$ a number of times during the 50 -year time-series. The stock has been able to withstand these periods of over-fishing due to the occasional recruitment of exceptionally strong year classes.

The fishery is mainly a trawl fishery, in some periods only as by-catch in the fishery for cod. Quotas restrict the fishery. The fishery is also regulated by a minimum catching size, a minimum mesh size in trawls and

Danish seine, a maximum by-catch of undersized fish, closure of areas with high density of juveniles, and other area and seasonal restrictions.

The analytical assessment is based on catch-at-age data and 3 surveys, and it includes predation by NEA cod.

### 3.1.4 Northeast Arctic saithe (Subareas I and II)

State of stock/exploitation: The stock is within safe biological limits. Fishing mortality in 2001 is below $\mathbf{F}_{\mathrm{pa}}$ and SSB in 2002 is well above $\mathbf{B}_{\mathrm{pa}}$. After a long period of low stock size, the stock recovered during the 1990s with the recruitment of several above-average year classes. The exploitation pattern has shifted to the older ages due in part to the increase in minimum landing size (1999).

Management objectives: There are no explicit management objectives for this stock. For management objectives to meet precautionary criteria, their aim should be to reduce or maintain fishing mortality below $\mathbf{F}_{\mathrm{pa}}$ and to increase or maintain spawning stock biomass above $\mathbf{B}_{\mathrm{p} \text { a }}$.

Precautionary Approach reference points (established in 1998):

| ICES considers that: | ICES proposes that: |
| :--- | :--- |
| $\mathbf{B}_{\text {lim }}$ is 89000 t , the lowest observed SSB in the 35-year <br> time-series | $\mathbf{B}_{\mathrm{pa}}$ is set at 150000 t , the SSB below which the <br> probability of poor year classes increases |
| $\mathbf{F}_{\text {lim }}$ is 0.45, the fishing mortality associated with potential <br> stock collapse | $\mathbf{F}_{\mathrm{pa}}$ be set at 0.26 . This value is considered to have a $95 \%$ <br> probability of avoiding the $\mathbf{F}_{\text {lim }}$ |

## Technical Basis:

| $\mathbf{B}_{\text {lim }}=\mathbf{B}_{\text {loss }}$ | $\mathbf{B}_{\mathrm{pa}}=$ examination of stock-recruit plot |
| :--- | :--- |
| $\mathbf{F}_{\text {lim }}=$ Median value of $\mathbf{F}_{\text {loss }}$ | $\mathbf{F}_{\mathrm{pa}}=\mathbf{F}_{\text {lim }} * 0.6$ |

## Advice on management: ICES advises that fishing mortality should be below $\mathrm{F}_{\mathrm{pa}}$, corresponding to a catch in 2003 of less than 168000 t .

Comparison with previous assessment and advice: Comparison with previous assessments shows that there has been a tendency to overestimate the fishing mortality in the assessment year.

Relevant factors to be considered in management: The estimation of incoming recruitment for forecasting purposes is difficult as the year classes are estimated by the acoustic survey after they have started recruiting to the fishery, and migration out from the near coast areas causes variation in the distributional availability of 2-year-old saithe.

## Catch forecast for 2003:

Basis: TAC; Landings (2002) $=152$; $\mathrm{F}(2002)=0.24$; $\operatorname{SSB}(2003)=370$.

| $\mathrm{F}(2003$ <br> onwards $)$ | Basis | Catch <br> $(2003)$ | Landings <br> $(2003)$ | SSB <br> $(2004)$ |

Weights in ' 000 t .
Shaded scenarios considered inconsistent with the precautionary approach.

Medium- and long-term projections: At $\mathbf{F}_{\text {status quo }}$ the catch is expected to increase slightly during the period, to 155000 t in 2007. At the same fishing mortality SSB is expected to increase to about 420000 t in 2006.

Elaboration and special comment: Since the early 1960s, the fishery has been dominated by purse seine and trawl fisheries, with a traditional gill net fishery for spawning saithe as the third major component. The purse seine fishery is conducted in coastal areas and fjords. Historically, purse seiners and trawlers have taken roughly equal shares of the catches. Recent regulation changes led to less relative amounts taken by purse seine in 2000 and in 2001.

Based on the TAC set and estimates of catches for other gears, quotas are set for purse seine and trawl fisheries. In the Norwegian fishery, quotas may be transferred between purse seiners and trawlers based on negotiations if it becomes clear that the quota allocated to one of the fleets will not be taken.

In addition to quotas, the fisheries are managed by minimum mesh size limitations, minimum landing size, by-catch regulations, and area closures. On March $1^{\text {st }}$ 1999 the minimum landing size was increased to 45 cm for trawl and conventional gears, and to 42 cm (north of Lofoten) and 40 cm (between $62^{\circ} \mathrm{N}$ and Lofoten) for purse seine, with an exception for the first 3000 t purse seine catch between $62^{\circ} \mathrm{N}$ and $65^{\circ} 30^{\prime} \mathrm{N}$, where the minimum landing size remains at 35 cm .

The analytical assessment is based on catch-at-age data, an acoustic survey data, and revised CPUE data from two commercial fleets.

### 3.1.5.a $\quad$ Sebastes mentella in Subareas I and II

State of stock/exploitation: The stock is considered to be outside safe biological limits. Although the current assessments are only indicative of the relative trends in stock size, they show that the spawning stock is close to its historical low. The 1991-2000 year classes are indicated to be well below those of the 1980s.

Management objectives: No explicit management objectives have been established for this stock. Consistent with the precautionary approach a management plan, including monitoring of the development of the stock and of the fishery, with corresponding regulations, should be developed and implemented.

Reference points: No precautionary reference points have been proposed for this stock, but candidate reference points for biomass are under investigation.

Advice on management: ICES recommends that there be no directed fishery on this stock until a significant increase in spawning stock biomass has been detected in surveys with a following increase in the number of juveniles. In addition, the by-catch of redfish in other fisheries should be reduced to the lowest possible level.

Relevant factors to be considered in management: Recruitment failure has been observed in surveys since 1991, and this indicates that the stock will decrease unless immediate action is taken. In this connection it is of vital importance that the juvenile age classes be given the strongest protection from being caught as by-catch in any fishery, i.e., the shrimp fisheries in the Barents Sea and Svalbard area. This will ensure that the recruiting year classes can contribute as much as possible to the stock rebuilding.

More than $50 \%$ of the 1987-1990 year classes (approx. $29-36 \mathrm{~cm}$ ) have currently recruited to the spawning stock. These year classes will be followed by at least 10 poor ones and consequently offer the last opportunity of increasing the spawning stock for a number of years to come. This opportunity will be lost unless the year classes are exploited with significantly reduced fishing mortality.

Based on estimates of current SSB and the size of year classes in the 1990s, this stock will not be able to support a directed fishery for at least several more years. Rather, it will be necessary to prevent the stock from declining further, to maintain measures to protect this stock from bycatch in other fisheries in the medium-term to SSBs much below any previously observed.

Comparison with previous assessment and advice: No significant changes.

Elaboration and special comment: The only directed fishery for $S$. mentella is a trawl fishery. In addition, bycatches are taken in cod and shrimp-trawl fisheries. After the introduction of sorting grids in 1993, discarding in the shrimp fishery was reduced. Small redfish less than 18-20 cm are, however, not sorted out by the grid, and criteria for the maximum number of redfish per kilogram shrimp are enforced ( 10 juvenile redfish per 10 kg shrimp). Additional protection for adult $S$. mentella comprise area closures.

Traditionally, the directed fishery was conducted by Russia and other East-European countries on grounds from south of Bear Island towards Spitsbergen. From the mid-1970s to the mid-1980s large catches were
taken annually. From the mid-1980s Norwegian trawlers started fishing along the continental slope (around 500 m depth) further south, on grounds never harvested before, and inhabited primarily by mature fish. After a sharp decrease in the landings from the traditional area until 1987, this fishery on new grounds resulted in a temporary increase in the landings until 1991, after which the landings declined. Since 1991 the fishery has been dominated by Norway and Russia.

Because of the slow growth of this species, the surveys should detect improvements to incoming year classes for several years before they contribute to the fisheries or the spawning population.

### 3.1.5.b $\quad$ Sebastes marinus in Subareas I and II

State of stock/exploitation: It has not been possible to assess the state of this stock with respect to safe biological limits. Available data from the Barents Sea/Svalbard surveys and commercial CPUE on larger fish do not indicate any large recent changes in the adult stock, but the data are too noisy to detect moderate changes. Results from the coastal and fjord survey series, however, indicate a decrease also for larger fish since 1995. Indices from surveys in young fish areas in the Barents Sea and Svalbard waters indicate a declining trend in recruitment.

Management objectives: No explicit management objectives have been established for this stock.

Reference points: No precautionary reference points have been proposed for this stock, but candidate reference points for biomass are under investigation.

Advice on management: Consistent with a precautionary approach, ICES recommends that a management plan, including monitoring of the development of the stock and of the fishery, with corresponding regulations, should be developed and implemented as a prerequisite to continued fishing.

Relevant factors to be considered in management: The low abundance of pre-recruit fish in the last year's surveys followed by a decreased survey abundance of
fishable biomass confirmed by reduced commercial catches are all signs of a disturbing stock decline.

Comparison with previous assessments and advice: The current assessment is just an update of last year's assessment, and all present available information confirms last year's evaluation of the stock status.

Elaboration and special comment: The fishery is mainly conducted by Norway accounting for $80-90 \%$ of the total catch. Germany also has a long tradition of a trawl fishery for this species. The fish are caught mainly by trawl and gillnet, and to a lesser extent by longline, Danish seine, and handline, in that order. Some of the catches are taken in mixed fisheries together with saithe and cod. Important fishing grounds are the Møre area (Svinøy), Halten Bank, outside Lofoten and Vesterålen, and at Sleppen outside Finnmark.

Except for some area restriction and by-catch regulations most of the fishery for S.marinus is at present a free fishery. This is not appropriate for the current stock situation.

Source of information: Report of the Arctic Fisheries Working Group, 16 - 25 April 2002 (ICES CM 2002/ACFM:18).

### 3.1.6 Greenland halibut in Subareas I and II

State of stock/exploitation: The state of the stock is uncertain. In the current assessment both the total stock size and SSB are considered to be low in historical terms, but have been improving slowly in recent years. Fishing mortality in the most recent years is estimated to be slightly below the long-term average. Recruitment has been rather stable, but low since 1990. The catch of Greenland halibut in 2002 is expected to be much higher ( 17000 t ) than the corresponding ICES advice ( $<11000 \mathrm{t}$ ).

Management objectives: No explicit management objectives have been established for this stock.

Reference points: No precautionary reference points have been proposed for this stock, but candidate reference points are under investigation.

Advice on management: ICES recommends to reduce catches to below 13000 t for 2003 in order to increase the stock. Furthermore, additional measures to control catches should be implemented.

Relevant factors to be considered in management: Although many aspects of the assessment remain uncertain, all fishery-independent indices of stock size indicate positive trends in recent years. However, given the uncertainties in the assessment a reduction in fishing mortality is desirable to ensure stock improvement. Current management measures have reduced fishing mortality somewhat. Additional management measures to control catches, e.g. TACs, area closures, and reduced by-catch limits, need to be introduced and enforced effectively. The rebuilding plan proposed in 2001 is aimed at increasing SSB. ICES still considers, cf. the advice above, that actions should be taken to increase SSB.

Over the past 10 years the average catch has been 13000 t and since the mid-1990s, SSB has steadily increased.

Comparison with previous assessment and advice: SSB in the 2001 assessment was estimated using a
maturity ogive for both sexes while the SSB given this year uses one for females only. This change caused a revision in the perception of the trend and status of the stock; the current assessment indicates a slight increase from a historical low in the mid-1990s and a slight reduction in estimated fishing mortality for 1999 and 2000 compared to the 2001 assessment.

Elaboration and special comment: The assessment is considered uncertain due to age-reading problems and evidence of unreported landings that could not be taken into account. Nevertheless, it is considered that the assessment reflects the state of the stock reasonably well.

Since 1992, the fishery has been regulated by allowing a directed fishery only by small coastal longline and gill net vessels. By-catches of Greenland halibut in the trawl fisheries have been limited by permissible by-catch per haul and an allowable by-catch retention limit on board the vessel.

An analytical assessment was based on commercial catch-at-age data, two survey series, and one experimental commercial CPUE series. This assessment is only accepted as indicative of trends.

Source of information: Report of the Arctic Fisheries Working Group, $16-25$ April 2002 (ICES CM 2002/ACFM:18).

### 3.1.7 Norwegian spring-spawning herring

State of stock/exploitation: The stock is inside safe biological limits. The stock is harvested at or slightly below $\mathbf{F}_{\mathrm{pa}}=0.15$. The recruitment of the very strong 1992 year class led to an increase in SSB in 1997 to approximately 9 million t , but SSB has since declined to just over 5 million t in 2001. The incoming year classes 1998 and 1999 are estimated to be strong.

Management objectives: EU, Faroe Islands, Iceland, Norway, and Russia agreed to implement a long-term management plan. This plan consists of the following elements:

1. Every effort shall be made to maintain a level of Spawning Stock Biomass (SSB) greater than the critical level ( $\boldsymbol{B}_{\text {lim }}$ ) of $2500000 t$.
2. For the year 2001 and subsequent years, the Parties agreed to restrict their fishing on the basis of a TAC consistent with a fishing mortality rate of less than 0.125 for appropriate age
groups as defined by ICES, unless future scientific advice requires modification of this fishing mortality rate.
3. Should the SSB fall below a reference point of $5000000 t\left(\boldsymbol{B}_{p a}\right)$, the fishing mortality rate, referred under paragraph 2, shall be adapted in the light of scientific estimates of the conditions to ensure a safe and rapid recovery of the SSB to a level in excess of 5000000 t. The basis for such an adaptation should be at least a linear reduction in the fishing mortality rate from 0.125 at $\boldsymbol{B}_{p a}(5000000 t)$ to $0.05 \boldsymbol{B}_{\text {lim }}(2500000 t$ ).
4. The Parties shall, as appropriate, review and revise these management measures and strategies on the basis of any new advice provided by ICES.

ICES considers that the objectives of this agreement are consistent with the precautionary approach.

Precautionary Approach reference points (established in 1998):

| ICES considers that: | ICES proposes that: |
| :--- | :--- |
| $\mathbf{B}_{\text {lim }}$ is 2.5 million t | $\mathbf{B}_{\mathrm{pa}}$ be set at 5.0 million t. |
| $\mathrm{F}_{\text {lim }}$ not considered relevant for this stock | $\mathbf{F}_{\mathrm{pa}}$ be set at $\mathrm{F}=0.15$ |

## Technical basis:

| $\mathbf{B}_{\mathrm{lim}}:$ MBAL | $\mathbf{B}_{\mathrm{pa}}: \mathbf{B}_{\mathrm{pa}}=\mathbf{B}_{\mathrm{lim}} * \exp (0.4 * 1.645)$ (ICES Study Group 1998) |
| :--- | :--- |
| $\mathbf{F}_{\text {lim }}:$ | $\mathbf{F}_{\mathrm{pa}}:$ ICES Study Group 1998 |

Advice on management: ICES advises that this fishery should be managed according to the agreed management plan, corresponding to a catch of 710 000 tin 2003.

Rebuilding plan: Incorporated to the agreed long-term management strategy.

## Catch forecast for 2003:

Basis: TAC constraint; Landings (2002) $=850 ; \mathrm{F}_{\mathrm{w}}(2002)$
$=0.17$; $\operatorname{SSB}(2002)=5300 ; \operatorname{SSB}(2003)=5800$.

| $\mathrm{F}_{\mathrm{w}}(2003)$ | Multiplier | Catch <br> $(2003)$ | Landings <br> $(2003)$ | SSB <br> $(2004)$ |
| :---: | :---: | :---: | :---: | :---: |
| 0.103 | $0.69^{*}$ <br> $\mathrm{Fw}(2001)$ | 600 | 600 | 5965 |
| 0.113 | $0.75^{*}$ <br> $\mathrm{Fw}(2001)$ | 650 | 650 | 5913 |
| 0.124 | $0.83^{*}$ <br> $\mathrm{Fw}(2001)$ | 710 | 710 | 5850 |
| 0.131 | $0.87^{*}$ <br> $\mathrm{Fw}(2001)$ | 750 | 750 | 5807 |
| 0.14 | $0.93^{*}$ <br> $\mathrm{Fw}(2001)$ | 800 | 800 | 5755 |
| 0.15 | $\mathrm{F}_{\mathrm{pa}}=1.0^{*}$ <br> $\mathrm{Fw}(2001)$ | 850 | 850 | 5703 |

Weights in '000 t.

For 2002 landings of 850000 t were assumed to correspond to the agreed TAC. In recent years the actual catch was close to the TAC, but in 2001 the catch was less than the TAC.
$\mathrm{F}_{\mathrm{w}}=$ weighted F , used in the management plan. Flat selection used from age 8 onwards.

Medium- and long-term projections: The medium-term view of the stock is very sensitive to the estimate of the 1999 year class. The 1999 year class is now estimated to be much lower than assumed last year. Therefore the medium term projections now indicate lower future yields and SSB.

Comparison with previous assessment and advice: Last year the spawning stock estimate for 2001 was 6.1 million $t$. This year's estimate of the spawning stock in 2001 is 5.2 million $t$. The catch forecasted for 2003 is lower than the catch forecasted in 2001 for 2002. This is due to lower estimates of recruitment than were used earlier.

Relevant factors to be considered in management: In spite of the strong 1998 and 1999 year classes, continued fishing under the present management agreement gives a
low probability of falling below $\mathbf{B}_{\text {lim }}$ in the medium-term, but a probability of about $50 \%$ of the spawning stock falling below $\mathbf{B}_{\mathrm{pa}}(5.0$ million t$)$.

Elaboration and special comment: The main catches from the fishery in 2001 were taken by Norway (495 000 t ), Iceland ( 78000 t ), Russia ( 109000 t ), and Faroe Islands ( 34000 t ). Lesser catches were taken by a number of EU fleets ( 54000 t ). The fisheries in general follow closely the migration of the stock as it moves from the wintering and spawning grounds along the Norwegian coast to the summer feeding grounds in the Jan Mayen and international areas. The Norwegian fishery exploits the stock as it migrates to and remains on the wintering areas and during the spawning period. The Icelandic fishery takes place mainly in May and June, and most catches are taken in international waters and in the Jan Mayen EEZ. The main Russian catches are taken along the shelf region of the Norwegian EEZ in spring as the stock moves from the spawning grounds, and also in August and September in the eastern part of the international area and in the Norwegian zone. The Faroese catches, taken mainly in spring and early summer, are from the Norwegian zone and from the Jan Mayen area. Most of the EU catches are taken in the international area and in the Norwegian zone.

A large increase in fishing effort, new technology, and environmental changes contributed to the collapse of this stock around 1970. Recruitment failed when the SSB was reduced below 2.5 million t . In the years following the collapse the aim was to rebuild the spawning stock above this minimum limit. In order to reach this goal, fishing mortality was kept low. However, recruitment remained poor and SSB increased only slowly until a very strong year class occurred in 1983. As this year class recruited, management between 1985 and 1993 aimed at restricting the fishing mortality to 0.05 , although the actual F was much higher in some years. Year classes after 1983 were
on average more than four times stronger than those produced between 1970 and 1982, and SSB continued to increase. Starting in 1989 a succession of above-average to very strong year classes were produced, promoting full recovery of the SSB and allowing expansion of fisheries. Up to 1994, the fishery was almost entirely confined to Norwegian coastal waters. Since 1992 the coastal fishery has increased sharply. During the summer of 1994 there were also catches in the offshore areas of the Norwegian Sea for the first time in 26 years. The geographical extent of this fishery increased in 1995, with nine nations participating and a total catch exceeding 900000 t . The fishery expanded further in 1996 and the annual level of the fishery was in the order of 1.2-1.5 million $t$ in the period 1996-2000. An international management agreement includes a TAC consistent with a maximum fishing mortality of $\mathrm{F}=0.125$ from 2002. A pre-agreed stock recovery strategy was introduced to the management agreement in 2001.

Juveniles and adults of this stock form an important part of the ecosystem in the Barents Sea and the Norwegian Sea. The herring has an important role as transformer of the plankton production to higher trophic levels (cod, seabirds, and marine mammals). It is therefore important to facilitate a high production of the herring.

A report based on the distribution of herring over the summer feeding areas in 2002 by an international ICES co-ordinated survey will be available in September 2002.

Data and assessment: Analytical assessment based on catch, survey data (acoustic surveys of adults and juveniles, larval index), and tagging data.

Source of information: Report of the Northern Pelagic and Blue Whiting Fisheries Working Group, 29 April - 8 May 2002 (ICES CM 2002/ACFM:19).

### 3.1.8 Barents Sea capelin (Subareas I and II, excluding Division IIa west of $5^{\circ} \mathbf{W}$ )

State of stock/exploitation: The stock is within safe biological limits. The maturing component in autumn 2002 was estimated to be 1.3 mill. tonnes, and is predicted to be 0.7 mill. tonnes at the time of spawning in 2003 without fishing. This is above $\mathbf{B}_{\mathrm{lim}}$ with a very high probability.

Management objectives: The fishery is managed according to a target escapement strategy, with a harvest control rule allowing (with $95 \%$ probability) the SSB to be above $\mathbf{B}_{\text {lim }}$, taking account of predation by cod.

## Reference points:

| ICES considers that: | ICES proposes that: |
| :--- | :--- |
| $\mathbf{B}_{\text {lim }}$ is set equal to 200000 t , which is above the $\mathrm{SSB}_{1989}$, <br> the lowest SSB that has produced a good year class. | $\mathbf{B}_{\mathrm{pa}}$ not defined (not relevant). |
| $\mathbf{F}_{\text {lim }}$ not defined (not relevant). | $\mathbf{F}_{\mathrm{pa}}$ not defined (not relevant). |

Advice on management: In order to stay above $B_{\text {lim }}$ with more than $95 \%$ probability, the catch in 2003 should be less than 310000 t . ICES further recommends that the fishery should be directed on the spawning stock in the period January-April.

## Relevant factors to be considered in management:

 The estimated annual consumption of capelin by cod has varied between 0.2 and 3.0 million $t$ over the period 1984-2001. Young herring consume capelin larvae, and this predation pressure is thought to be one of the causes for the poor year classes of capelin in the periods 1984-1987 and in 1992-1994. The abundance of herring in the Barents Sea is expected to increase from a low level in 2002 to an intermediate level in 2003.There is no direct measurement of the SSB at spawning time for this stock. The SSB is estimated based on the results of the survey in September/October and projections taking into account growth, maturation, and mortality, as well as uncertainties in these parameters and in the survey. Hence, the historical estimates in Table 3.1.8.2 are median values of the modelled stochastic SSB and will change e.g. if there are changes in the historical stock values for Northeast Arctic cod. For this stock, a $\mathbf{B}_{\text {lim }}$ equal to the value of the 1989 spawning stock biomass, which is the lowest SSB having produced an outstanding year class, at least after 1980, is considered a good basis for such a reference point in a non-herring situation. The median value of the 1989 spawning stock biomass is 96000 t , adjusted upwards from 69000 t last year. The assessment method may not yet account for all sources of uncertainty, and there are inconsistencies in the data series. Thus, it is considered appropriate to use a somewhat higher value for $\mathbf{B}_{\text {lim }}$. The $\mathbf{B}_{\text {lim }}$ currently adopted by ICES is 200000 t .

Keeping the stock above $\mathbf{B}_{\text {lim }}$ is intended to be a safeguard against recruitment failure. The expectation is that recruitment would be larger at a spawning stock larger than $\mathbf{B}_{\mathrm{lim}}$. Furthermore, herring can have a negative influence on capelin recruitment and such an effect should be considered if it can be quantified. Adjustment of the harvest strategy, perhaps including a target biomass reference point, should also be investigated to take the uncertainty in the predicted amount of spawners together with the role of capelin as a prey item into account.

Catch forecast for 2003: The spawning stock in 2003 is projected from the acoustic survey in SeptemberOctober 2002. For catches in 2003 below 310000 t , the probability of having an SSB below 200000 t is less than $5 \%$, and with a catch of 310000 tonnes, the expected SSB is 440000 t . Only catches of mature fish have been considered. The proportion of large fish (suitable for human consumption) in the spawning stock is similar to the three previous years, but high compared to most years in the time-series.

Elaboration and special comments: The spawning stock in 2003 will consist almost exclusively of fish from the 1999 and 2000 year classes. The survey estimate at age 1 of the 2001 year class is the lowest since the 1994 year class, and is far below the long-term average. Observations during the international 0 -group survey in August 2002 indicated that the size of the 2002 year class is somewhat above the long-term mean.

Since 1979, the fishery has been regulated by a bilateral agreement between Norway and Russia (formerly USSR). The catches have been very close to the advice in all years since 1987.

The assessment and stock history is based on joint Russian-Norwegian acoustic surveys mainly during September each year. From 1998 onwards, a model incorporating predation from cod has been used for predicting SSB and for estimating the historical timeseries of SSB.

Sources of information: Report from the 2002 joint Russian-Norwegian meeting to assess the Barents Sea capelin stock, Kirkenes, October 7-9, 2002. Report of the Northern Pelagic and Blue Whiting Fisheries Working Group, April-May 2002 (ICES CM 2002/ACFM:19).

${ }^{1}$ Preliminary values.

Barents Sea CAPELIN. Stock summary table. Recruitment and total biomass are survey estimates back-calculated to 1 August (before the autumn fishing season). Maturing biomass is the survey estimate of fish above maturity length $(14.0 \mathrm{~cm})$. SSB is the median value of the modeled stochastic spawning stock biomass (after the winter/spring fishery).

${ }^{1}$ Is probably an underestimate, since the vessel was not allowed to work in Russian EEZ.

### 3.1.9 Northern Prawn (Pandalus borealis)

State of stock/exploitation: This stock is probably within safe biological limits. Surveys indicate that the biomass is lower than the long-term mean (1984-2001) (Figure 3.1.9.1). No estimates of fishing mortality are available. Fishing effort for both Russia and Norway declined in 2001.

Management objectives: There are no explicit management objectives for this stock.

Reference points: No precautionary reference points have been proposed for this stock.

Advice on management: ICES advises that current catch rates are sustainable.

Relevant factors to be considered in management: Shrimp is an important prey for several fish species, especially cod. Consumption by cod significantly influences shrimp population dynamics and should be taken into account in management. Cod consumption estimates are on average much higher than shrimp landings (Figure 3.1.9.3). The biomass of shrimp consumed by cod decreased in 2001. Survey indices since 1985 indicate that the shrimp biomass has varied cyclically without trend over that period.

Elaboration and special comment: Reported landings for all countries show a substantial increase in catches between $1995(25000 \mathrm{t})$ and $2000(83000 \mathrm{t})$ and a
significant decrease in 2001 (Table 3.1.9.1). Catch increases from 1994-1999 encouraged the fishery to invest in larger vessels and new technology. The adoption of multiple trawl gears, predominantly by Norway, is not accounted for in the Norwegian CPUE series (Figure 3.1.9.2).

In the Svalbard area the shrimp fisheries are regulated by the number of effective fishing days and the number of vessels by country. In the Barents Sea and Svalbard area, Norwegian rules stipulate that the fisheries are to be regulated by the smallest allowable shrimp size (a maximum $10 \%$ of the catch weight may consist of shrimp less than 15 mm carapace length, CL) and by provisions of the fishing licenses. The Russian Economic Zone TAC is established each year by Russian authorities. In the Barents Sea and the Svalbard area fishing grounds are closed if by-catch limits for cod, haddock, redfish, or Greenland halibut are exceeded.

No analytical assessment is available. Commercial CPUE series and survey series are considered to be of reasonable quality, although in the future account will have to be taken of efficiency increases due to the use of multi-rig trawls.

Source of information: Report of the Arctic Fisheries Working Group, 16 - 25 April 2002 (ICES CM 2002/ACFM:18).

### 3.2.1 Overview

## The fisheries

Stocks in the northwestern areas have been exploited mainly by Icelandic vessels since the mid-seventies. However, vessels of other nationalities have also been operating in Subareas XII and XIV during this period. In the most recent years freezer and factory trawlers of various nationalities have been increasing in number in the pelagic deep-water fishery on redfish in Subareas XII and XIV. Norwegian vessels have also taken part in the capelin fishery, mainly in the Jan Mayen area.

The fisheries for the main pelagic species, Icelandic summer-spawning herring and capelin in the IcelandEast Greenland-Jan Mayen area, are almost exclusively carried out by purse seiners, although in recent years catches of herring by pelagic trawls have increased. The demersal species are mainly exploited by stern trawlers but considerable fisheries for cod are also carried out by gillnets, longline and handline. In general, effort is considered to have stabilised at high levels in recent years. Exceptions to this include the fisheries on herring and capelin, where harvest control rules have been implemented. Fisheries in these areas use the most up-to-date equipment both for navigation and in fishdetection. More effective fishing gears have been introduced in the fisheries, not least pelagic trawls, but there have also been substantial improvements of other gears such as bottom trawl, longline, and handline. New fishing technology permits fishing deeper with pelagic trawls.

## Management measures

The demersal fisheries have been managed by TACs since 1984 and the pelagic fisheries since the seventies (except for pelagic redfish, which have been regulated since 1989). Fisheries in these areas are managed on a transferable quota system basis considered to lead to economic benefits in the long term. Each vessel (or factory) is allocated a proportion of the TAC of a fish stock and this proportion can be traded on a free-market. All fisheries are subject to a range of other management measures such as fishing gear regulations, closed areas, and closed seasons. Efforts have been made to prohibit discards through the introduction of a minimum catching size instead of a minimum landing size. These measures, however, are partly counterbalanced by other constraints on the fisheries such as quotas.

## The state of stocks

The fish stocks considered in this report include the largest stocks in these areas: capelin, cod, and redfish. These and other species spawn in the warmer regions of Atlantic water, but they differ substantially in their distribution patterns during other periods of their life
cycle. Greenland halibut and deep-sea Sebastes mentella are the only demersal deep-water species among the stocks considered. Saithe is migratory and migrations between Norway and Iceland have been observed. Pelagic redfish (both pelagic deep-sea and oceanic Sebastes mentella) constitute a vast resource although increasing effort is directed towards it. A number of other demersal commercial stocks inhabit both the continental shelf, e.g. flatfish species, and deeper waters, e.g. ling, blue ling, and tusk. Most of these stocks are regulated by TACs.

Most of the largest stocks have been at low levels during the most recent decade. Deep-sea S. mentella on the shelf is stable at a low level. Due to good recruitment in recent years the haddock is expected to increase rapidly. Saithe and Greenland halibut stock have both been declining for more than a decade but seem now to be starting to rebuild slowly. The capelin stock is considered to be at a relatively high level of stock biomass. The Icelandic summer-spawning herring has been increasing steadily during the last two decades and is at a higher level of stock size than observed in previous periods. Further information on the demersal stocks at Greenland and Iceland are given in a later section of this overview.

## Other issues

The resources in the area have generally been managed on the basis of fairly long and detailed time-series of data. There are well known difficulties with the assessments, for example age readings of slow-growing species such as redfish and Greenland halibut. The problems are the same in these areas as elsewhere. Greenland halibut, pelagic redfish stocks in the Irminger Sea (Subareas XII and XIV), and deep-sea S. mentella on the shelf (Subareas V, XII and XIV) are the stocks with the most apparent need for improvements in data analysis and in the gathering of auxiliary information. Such auxiliary information required is trawl abundance or acoustic stock indices. Comprehensive assessment of these large and widely distributed stocks is a challenging task, which requires full-scale international cooperation.

Interaction between commercially valuable species is frequently observed but appears to be most pronounced for few species. The most important predator-prey relationships are the cod-capelin and cod-Pandalus interactions. Cod growth depends on capelin abundance and cod predation influences the recruitment of Pandalus. The high abundance of deep-water Pandalus in Icelandic waters in recent years is considered to be a result of this interaction caused by the low cod stock. Baleen whales have not been harvested commercially for some time and a continued increase in the
abundance of cetaceans is likely to result in increased natural mortality on stocks such as cod in Division Va.

## Demersal stocks at Greenland and Iceland

The cod at Greenland and Iceland have four components spawning in different areas: A West Greenland offshore component spawning off Southwest Greenland (now virtually non-existing), an inshore component found in various West Greenland fjords, a component spawning off East Greenland, and a component spawning off Iceland. Eggs and larvae from the East GreenlandIceland components are carried by the Irminger current to West Greenland. The inflow of larvae varies from year to year but for some year classes, such as those of 1973 and 1984, this inflow was very important.

Emigration of mature offshore cod from West Greenland is well known and most evident for year classes which were earlier observed as 0 -group drifting from Iceland to Greenland.

The fishery off West Greenland has traditionally consisted of an offshore trawl fishery and an inshore fishery mostly using poundnets. The catches have fluctuated substantially, but declined dramatically after 1989, and the offshore fishery has now ceased.

Cod catches off East Greenland have also fluctuated widely and decreased sharply in 1993, when the directed cod fishery failed totally due to very low catch rates.

All available information confirms the severely depleted state of the cod stock off Greenland. The offshore stock may be considered to be almost non-existent at the present time. Strong year classes observed at Iceland as 0-groups in 1997-1999 only appeared as moderate at age 1 in bottom trawl surveys in Greenland waters. A rise in water temperatures at East- and West Greenland may provide the basis for a higher recruitment to the West Greenland area. The inshore stock component has historically been small and available information indicates that recruitment will be low during the next few years.

In Icelandic waters, the cod stock has shown signs of some recovery due to better recruitment of 1997-2000 year classes after a long period of poorer recruitment. The Icelandic saithe stock is considered to be outside safe biological limits. Saithe is taken in mixed fisheries with cod. The Icelandic haddock has for more than a decade been exploited at a very high fishing mortality. The stock is increasing from a low level in recent years. Several strong year classes have entered or are expected to enter the fishery.

The fishery for Greenland halibut in Subareas V and XIV is conducted by various nations but is still dominated by Icelandic trawlers in Division Va. The fishery in Divisions XIVb and Vb constitutes now about a third of the total fishery for Greenland halibut within Subareas V and XIV. Surveys have only recently been initiated for Greenland halibut. All indices, surveys as well as commercial CPUEs, suggest that the stock has stabilised and may be rebuilding slowly.

### 3.2.2 Cod

### 3.2.2.a Greenland cod (ICES Subarea XIV and NAFO Subarea 1)

State of stock/exploitation: The stock is outside safe biological limits. The offshore component is severely depleted since 1990 with some recovery potential as derived from recent survey indices. The dramatic decrease in stock abundance was associated with changes in environmental conditions, emigration and high fishing mortalities. Inshore catches and CPUE are presently low and both have declined continuously since 1991. Recruitment to the inshore component has been poor since the 1993 year class and indices indicate that the inshore stock is still declining. Only the offshore catches in Greenland are subject to a TAC regulation. The inshore fishery is unregulated. This gives cause for concern about the exploitation rate of the inshore component.

Management objectives: Greenland and EU established an agreement on fisheries valid from 2001 to 2006. A variable TAC regulation has been agreed, with annual TACs adjusted to take account of ICES advice on stock status. The agreement also provides for a transfer of catches into future years, should a rapid increase in stock occur.

No reference points have been proposed for this stock, so the Agreement cannot be evaluated relative to the Precautionary Approach. However, TAC for 2002 is not consistent with the current ICES advice, and ICES stresses that any multi-year management plan should ensure that fisheries do not expand until a substantial increase in biomass and recruitment is evident.

Advice on management: ICES recommends that no fishery should take place until a substantial increase in biomass and recruitment is evident. A recovery plan for both the inshore and offshore components should be developed in order to take advantage of strong year classes when they occur and to protect all inshore spawning components.

Relevant factors to be considered in management: Technical measures to avoid the by-catch of juvenile cod should be maintained (mandatory use of a 22 mm sorting grid since October 1, 2000).

Comparison with previous assessment and advice: The advice is the same as last year. The last analytical assessment was performed in 1996.

Elaboration and special comment: The historic fishery was mainly targeted at cod with some redfish as a by-catch. The fishery was international until the declaration of EEZs in the 1970s. During the 1980s EU vessels, mainly freezer trawlers, dominated the offshore fishery. During the late 1980s the offshore fishery was based almost exclusively on the 1984 and 1985 year classes. Thereafter, a total failure of the directed cod fishery indicated a stock collapse.

In Greenland waters there are inshore fjord stocks and offshore stocks. Given suitable climatic conditions (water temperature) and prudent management, sustained production of offshore cod is possible. However, interaction between the East Greenland and Irminger currents during the early 1970s and 1980s has apparently rendered climatic conditions unsuitable for offshore cod in some years. Combined with high fishing mortality, this caused the offshore cod stock to be severely depleted. In order to take advantage of suitable climatic conditions when they occur, it is necessary to protect the remaining biomass of offshore cod.

### 3.2.2.b Icelandic cod (Division Va)

State of stock/exploitation: SSB is currently estimated to be about $285000 \mathrm{t}, 70000 \mathrm{t}$ above its historic low of 215000 t (1983) but well below the long-term average of 480000 t , and the current (2001) F of 0.81 is well above $\mathbf{F}_{\text {med }}$. Recruitment was poor or below average for the year classes 1985-1996. The 1997 to 2000 year classes are estimated at about average size, but the first signs of the 2001 year class indicate that it is very poor. Fishing mortality dropped markedly in 1994 and 1995 in accordance with the measures taken by Iceland to reduce fishing effort against cod, but has increased since then.

Management objectives: A formal Harvest Control Rule was implemented for this stock in 1995. The TAC for a fishing year was set as a fraction ( $25 \%$ ) of the "available biomass", which is computed as the biomass of age 4 and older fish, - $\mathrm{B}(4+)$ - averaged over the two adjacent calendar years. In the long term, this should correspond to a fishing mortality of about 0.4 . That harvest control rule was considered to be in accordance with the precautionary approach.

In spring 2000 the government introduced an amendment to the catch rule limiting interannual changes in catches to 30000 t . Limited studies, using a similar approach as when the initial catch rule was adopted were the basis for this amendment. ICES has not evaluated the amendment. Changes in the catch from 2002 to 2003 according to the harvest control rule are less than 30000 t .

Precautionary Reference Points: Reference points have not been defined for this stock.

Advice on management: ICES advises to apply the Harvest Control Rule, which takes 25\% of the 4+ biomass, corresponding to a projected catch of 183000 t in 2003.

Relevant factors to be considered in management: The catch consistent with the application of the Harvest Control Rule results in an estimated $\mathrm{F}(5-10)$ of 0.45 in 2003, which is somewhat above the expected value $(0.40)$ when the HCR was adopted.

The stock was overestimated in the years 1998-2000, but the current assessment is more consistent with previous year's assessment. The overestimation in 1998-2000 as well as the application of the amended catch rule, lead to considerably higher realized fishing mortality in recent years than was intended. Failure of the HCR to reduce F or rebuild SSB can be attributed to this pattern of overestimating stock size as well as the excessive catches allowed by the 30000 t stabilizer in the amended catch rule. A working group was set up by the Icelandic Ministry of Fisheries in 2001 with the objectives to analyse the experience of using the HCR and try out alternative approaches, taking into account
obvious shortcomings of the current harvest control rule. This working group should deliver a preliminary report before the start of the next fishing year September $1^{\text {st }} 2002$.

At present fishing mortality is high ( $\mathrm{F}(5-10$ ) in 2001 about 0.8 ), and ages 4 and 5 account for more than $70 \%$ of the fishable biomass (4+). This will be reflected in the age composition of the catches in 2003 where age group 6 and younger will represent about $80 \%$ of the landings. The age composition of the spawning stock is highly skewed. Spawners at age 5 and younger will constitute about $60 \%$ of the spawning stock biomass in 2003, and fish older than 10 years less than $4 \%$. Increased age diversity has been shown to be associated with improved recruitment for this stock. Taking into account the relatively high proportions of young fish in both the fishable as well as in the spawning stock, and considering that the fishing mortality has never been at or lower than the intended F since the implementation of the catch rule, management authorities should consider setting a TAC for 2003 that would generate an F less than 0.40 .

Catch forecast for 2003:
Basis: TAC/national estimates. Landings $(2002)=190$; $\mathrm{F}(2002)=0.59 ; \mathrm{B}(4+, 2002)=680 ; \operatorname{SSB}(2002)=285$; $\mathrm{B}(4+, 2003)=785$.

| $\mathrm{F}(2003$ <br> onwards $)$ | Basis | Catch <br> $(2003)$ | SSB <br> $(2003)$ | $\mathrm{B}(4+)$ <br> $(2004)$ | SSB <br> $(2004)$ |
| :---: | :---: | :---: | :---: | :---: | :---: |
| 0.32 | $0.4 \mathrm{~F}(01)$ | 138 | 367 | 1023 | 489 |
| 0.41 | $0.5 \mathrm{~F}(01)$ | 167 | 360 | 987 | 458 |

| 0.81 | $1.0 \mathrm{~F}(01)$ | 294 | 328 | 837 | 336 |
| 0.97 | $1.2 \mathrm{~F}(01)$ | 336 | 316 | 787 | 300 |

Weights in '000 t.
Shaded scenarios considered inconsistent with the precautionary approach.

Medium- and long-term projections: Medium-term projections based on the amended catch control rule indicate low probability that the fishable biomass (age $4+$ ) will remain as low as observed in the last decade (Figure 3.2.2.b.1).

Comparison with previous assessment and advice: The fishable biomass 4+ in 2001 was estimated at 577000 t in last year's assessment compared to 640000 t in the current assessment. This difference of 63000 t , or $11 \%$, is well within the confidence limits of last year's point estimate. The observed increase in the mean weight at age for the age groups $4-8$, compared to last years prediction, accounts for about $2 / 3$ of the discrepancies, but the rest is caused by a relatively small differences in the estimated stock in number in 2001. The SSB is now estimated to have been 311000 t at spawning time in the
year 2001. Last year's estimate of 219000 t was markedly lower. The sharp increase in the observed maturity-at-age in 2001 for age groups 3-7 does account for the bulk of this increase, but some increase in mean weight at age was also observed for age groups less than 10 in the SSB.

The year classes 1997-2000 were estimated at 185, 170, 185 , and 175 millions, respectively, in last year's assessment compared to $180,165,176$, and 210 in the current assessment.

The main causes of the overestimation of this stock in the years 1998-2000 are now considered to be the use of a combination of commercial CPUE and survey indices for calibration of stock assessment models and high availability of cod in the years 1997 and 1998. The causes for the presumed increase in availability in those years are still not understood. Many factors have been mentioned such as: hydrographical changes, capelin availability, increased availability with reduced effort (disturbance), variable natural mortality, emigration, increased discards, etc.

Elaboration and special comment: In order to protect juvenile fish, fishing is prohibited in areas where the number of small cod ( $<55 \mathrm{~cm}$ ) in the catches exceeds $25 \%$.

The catch estimates are based on landings only. The amount of discarding has not been documented.

From 1977-1983, demersal fishing was limited to a certain number of days each year, but this system, as implemented, failed to meet the objective of limiting fishing mortality and a transferable boat quota system was introduced in 1984. TACs are set for each fishing year, which runs from 1 September through to 31 August in the following year. Catches have exceeded national advice and national TACs considerably for the past decade.

ICES TAC advice on this stock was first given for 1993. In the most recent years catches have been close to the agreed TAC.

Based on extensive simulation work indicating that the biomass would grow under the catch rule, ICES concluded that the $25 \%$ catch rule adopted by Iceland for Icelandic cod was consistent with the precautionary approach. Realised fishing mortalities since the implementation of the catch rule have generally exceeded $\mathbf{F}_{\text {med }}=0.52$, while $\mathrm{F}=0.4$ was expected from the long-term application of the catch rule. The estimate of the percentage has been

| 1995 | 1996 | 1997 | 1998 | $1999 /$ | $2000 /$ | $2001 /$ |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| $/ 96$ | $/ 97$ | $/ 98$ | $/ 99$ | 2000 | 2001 | 2002 |
| $27 \%$ | $27 \%$ | $30 \%$ | $35 \%$ | $39 \%$ | $37 \%$ | $35 \%$ |

In years of high recruitment a larval drift to Greenland is sometimes observed, resulting in a large year class at Greenland as well. In some other years an immigration of adult cod from Greenland has taken place, which has been taken into account in the assessment.

Data and assessment: The analytical assessment is based on catch and survey data using the TSA programme. Exploratory assessments with similar data inputs, using five alternative software products with three different assessment models, gave similar results. Catch-at-age data as well as survey indices are considered reliable.

### 3.2.3 Icelandic haddock (Division Va)

State of stock/exploitation: The SSB decreased from the early 1990 to 2000-2001 when it was the second lowest in the last two decades, but it increased by $30 \%$ from 2001 to 2002 due to the strong 1998 year class. Recruitment and spawning stock fluctuate widely. The strong year class from 1995 is now mostly fished out, but there is evidence from the Icelandic groundfish survey that year classes 1998-2000 are all very strong. Fishing mortality has been high and above the $\mathbf{F}_{\mathrm{pa}}$ since 1984, showing an increasing trend since 1996.

Management objectives: There is no explicit management objective for this stock.

Precautionary Approach reference points: $\mathbf{F}_{\mathrm{pa}}(=.47)$ equal to $\mathbf{F}_{\text {med }}$ was provisionally proposed in 2000.

Advice on management: ICES advises that fishing mortality in 2003 should be reduced to below the provisionally proposed $\mathrm{F}_{\mathrm{pa}}=0.47$, which corresponds to a catch of less than 55000 t.

Relevant factors to be considered when managing this fishery: SSB and recruitment are highly variable. SSB is relatively low, but is forecast to increase in coming years due to good recruitment.

Discard and mortality of haddock slipping through gear meshes are potentially problems, which, if taken into account, would lower the fishing mortality that maximises yield. Figures on discards indicate that they were relatively high from 1994 to 1997, but reduced after that. Discards in the projection period are anticipated to be relatively small.

Catch forecast for 2003:
Basis: TAC/National estimates ${ }^{1}$ : Landings $(2002)=45$, $\mathrm{F}(2002)=0.57, \mathrm{SSB}(2003)=98$.

| $\mathrm{F}(2003)$ | Basis | Landings <br> $(2003)$ | SSB (2004) |
| :---: | :---: | :---: | :---: |
| 0.17 | $\mathbf{F}_{0.1}$ | 22 | 156 |
| 0.47 | Provisional <br> $\mathbf{F}_{\mathrm{pa}}$ | 55 | 132 |
| 0.57 | F 2002 | 65 | 125 |
| 0.75 | F 2001 | 81 | 114 |
| 0.94 | 1.25 F 2001 | 95 | 103 |

${ }^{1}$ Based on landings in the first 4 months of 2002. Weights in ' 000 t .
Shaded scenarios considered inconsistent with the precautionary approach.

Medium- and long-term projections: Assuming that the harvesting strategy of $\mathrm{F}=0.47$ is followed, there is high probability that the fishable biomass will increase in the short term (Figure 3.2.3.1). Later development is dependent on future recruitment.

Comparison with previous assessment and advice: The present assessment is more optimistic about the state of the stock than last year's assessment. This change in perception of the stock is mostly driven by the groundfish survey 2002 which gives a more optimistic view of the incoming year classes than the two previous surveys (Figure 3.2.3.1). Estimates of incoming year classes from the surveys 2001 and 2002 are unusually contradicting, with the 2002 survey indicating much higher recruitment (Table 3.2.3.3, Figure 3.2.3.2).

Stock numbers have been reliably assessed in the past, but the estimated biomass was consistently too high due to over-estimated weights-at-age. This has possibly led to higher fishing mortalities than intended. A revision of the stock weights in 1999 is thought to have alleviated this problem.

Elaboration and special comment: Iceland extended its fisheries jurisdiction to 200 miles in 1975, resulting in a temporary reduction in fishing mortality. In the demersal fisheries, the mesh size in trawls increased from 120 mm to 135 mm in 1976 and to 155 mm the following year. From 1977-1983, demersal fishing was limited by a number of days each year. As this system failed to limit fishing mortality a transferable boat quota system was introduced in 1984. TACs are set for each fishing year ( 1 September to 31 August).

The Icelandic haddock stock is subject to substantial fluctuations in SSB and recruitment, with large year classes dominating the catch in some years. The data from the currently available time-series do not indicate reduced recruitment at low SSB.

Data and Assessment: The analytical assessment is based on catch and survey data using the same settings as in 2001.

Source of information: Report of the Northwestern Working Group, 29 April - 8 May 2002 (ICES CM 2002/ACFM:20).

Yield and spawning biomass per Recruit F-reference points:

|  | Fish Mort <br> Ages 4-7 | Yield/R | $\mathrm{SSB} / \mathrm{R}$ |

Figure 3.2.3.3 Haddock in Division Va. Results from simulations fishing at $\mathrm{F}=0.47$ after 2002. Assessment error lognormal with $\mathrm{CV}=0.1$. Shown in the figure are 5 and 95 percentiles (shaded areas), 25 and 75 percentiles (dashed lines) mean and median.

### 3.2.4 Saithe in Icelandic waters (Division Va)

State of stock/exploitation: The stock is outside safe biological limits. SSB is below $\mathbf{B}_{\mathrm{pa}}$ and close to $\mathbf{B}_{\mathrm{lim}}$. Fishing mortality has been above $\mathbf{F}_{\mathrm{pa}}(0.30)$ for all years except two during the last two decades. Since 1997, fishing mortality has been gradually reduced and $\mathrm{F}_{2001}$ is estimated close to $\mathbf{F}_{\mathrm{pa}}$. Recruitment has been below the long-term average since 1989.

Management objectives: There is no explicit management objective for this stock. However, for any management objective to meet precautionary criteria, F should be less than $\mathbf{F}_{\mathrm{pa}}$ and spawning stock biomass should be greater than $\mathbf{B a}_{\mathrm{pa}}$.

Precautionary Approach reference points (unchanged since 1999):

| ICES considers that: | ICES proposed in 1998 that: |
| :--- | :--- |
| $\mathbf{B}_{\text {lim }}$ is set tentatively at 90000 t | $\mathbf{B}_{\mathrm{pa}}$ be set at 150000 t |
| $\mathbf{F}_{\text {lim }}$ is as yet undefined | $\mathbf{F}_{\mathrm{pa}}$ be set at 0.3 |

## Technical basis:

| $\mathbf{B}_{\text {lim }}: \mathbf{B}_{\text {loss }}$ estimate in 1998 | $\mathbf{B}_{\mathrm{pa}}:$ observed low SSB values in 1978-1993 |
| :--- | :--- |
| $\mathbf{F}_{\text {lim }}:$ | $\mathbf{F}_{\mathrm{pa}}:$ fishing mortality sustained for 3 decades |

Advice on management: ICES advises that the fishing mortality is reduced to $2 / 3$ of $F_{p a}$ as a first step to rebuild the stock. This corresponds to a fishing mortality of 0.20 and a catch of $24000 \boldsymbol{t}$ in 2003. A rebuilding plan should be developed.

Relevant factors to be considered by management: Recruitment has been consistently low since 1989. A reduction in fishing mortality is advised both for cod and haddock in Division Va. To the extent that saithe is caught in mixed demersal fisheries, a general effort reduction will help to improve the exploitation also for saithe, but measures need to be taken to keep by-catches of saithe in mixed fisheries as low as possible.

## Catch forecast for 2003:

Basis: TAC: Landings $(2002)=37 ; F(2002)=0.35$ $(=1.04 \mathrm{~F}(2001)) ; \quad \operatorname{SSB}(2003)=105$. No discards assumed.

| $\mathrm{F}(2003$ <br> onwards $)$ | Basis | Landings <br> $(2003)$ | SSB (2004) |
| :---: | :---: | :---: | :---: |
| 0 | 0 | 0 | 147 |
| 0.20 | $0.6 \mathrm{~F}(2001)$ | 24 | 125 |
| 0.25 | $0.75 \mathrm{~F}(2001)$ | 30 | 122 |
| 0.27 | $0.8 \mathrm{~F}(2001)$ | 32 | 121 |
| 0.30 | $\mathrm{~F}_{\mathrm{pa}}=0.9 \mathrm{~F}(2001)$ | 35 | 116 |
| 0.33 | $\mathrm{~F}(2001)$ | 38 | 113 |
| 0.41 | $1.2 \mathrm{~F}(2001)$ | 45 | 108 |

Weights in '000t. Shaded scenarios considered inconsistent with the precautionary approach.

Comparison with previous assessment and advice: Last year's assessment indicated that SSB had been
below $\mathbf{B}_{\text {lim }}$ since 1998 and did not show clear signs of improvements. This led to advice for no directed fishery. This year's assessment indicates that SSB was below $\mathbf{B}_{\text {lim }}$ from 1997 to 2000, but has been increasing since 1999 and was above $\mathbf{B}_{\text {lim }}$ in 2001. Also estimates of the recent fishing mortalities are somewhat lower and recruitment somewhat higher in the current assessment than in last year's assessment. Together these factors suggest that the stock has begun to rebuild in the most recent years, although slowly. Hence, the most severe catch restrictions possible are no longer considered essential, but strict controls on F will be necessary for several years, in order to rebuild the stock above $\mathbf{B}_{\text {pa }}$.

Elaboration and special comment: Time-series analysis (TSA) tuned with survey was used to estimate fishing mortalities. Migrations from other stocks were included in the stock assessment for the third time. ADAPT and XSA (with revised settings) tuned with survey data gave comparable results with TSA. Saithe are taken in a mixed demersal fishery although they may be targeted at certain times, especially in times of high stock abundance. In order to protect juvenile fish, fishing is prohibited in areas where the number of small saithe in the catches exceeds a given percentage.

ICES recommends to evaluate the possibility of imposing closed areas to protect spawning aggregations of saithe.

### 3.2.5 Greenland halibut in Subareas $V$ and XIV

State of stock/exploitation: The stock is harvested outside safe biological limits. Recent Fs are estimated to be above the proposed $\mathbf{F}_{\mathrm{pa}}$ and close to $\mathbf{F}_{\mathrm{MSY}}$. Even though the recent historical development of SSB and fishing mortality are not well estimated, it is likely that fishing mortality has decreased and biomass increased in recent years. Survey biomass indices have increased to some extent from a low in 1996.

Management objectives: There are no explicit management objectives for this stock.

Precautionary Approach reference points: The ASPIC model provides estimates of the biomass relative to $\mathbf{B}_{\mathrm{MSY}}$ and of F relative to $\mathbf{F}_{\mathrm{MSY}}$. The ratio $\mathrm{F} / \mathbf{F}_{\mathrm{MSY}}$ equal to 0.67 is used in the advice as an upper boundary for F .

Advice on management: ICES recommends that the fishing mortality be reduced below $0.67 * \mathrm{~F}_{\text {MSY }}$. This corresponds to catches in 2003 for the total stock of less than 23000 t.

Relevant factors to be considered in management: For a number of years total catches have exceeded the advised TAC. The management approaches in the three areas (Divisions $\mathrm{Va}, \mathrm{Vb}$, and XIVb ) differ. At present the fishery in Division Vb is subject to effort limitation and the fisheries in Divisions XIVb and Va are catch limited. The agreed TAC in Division Va has been close to the recommended TAC for the entire area. The
combination of different management measures in different Subareas means that there is no control over total fishing mortality for this stock.

Medium- and long-term projections: Forward projections of population biomass and fishing mortality were made under three different harvesting regimes, including estimates of uncertainty, assuming a catch in 2002 of 30000 t . Fishing at $\mathbf{F}_{\mathrm{pa}}\left(2 / 3 \mathbf{F}_{\mathrm{MSY}}\right)$, it is expected that the biomass will increase and have a $50 \%$ probability of reaching $\mathbf{B}_{\mathrm{MSY}}$ by 2005 . Fishing at $\mathbf{F}_{\text {sq }}$ $\left(\sim \mathbf{F}_{\mathrm{MSY}}\right)$, the biomass will increase more slowly, and it is expected to have at least a $50 \%$ probability of reaching $\mathbf{B}_{\mathrm{MSY}}$ by 2007. Fishing at 30000 t annually implies a considerable risk that the stock will remain low.

Comparison with previous assessment and advice: The advice is based on a production model as was done last year, and the results and advice are consistent.

Elaboration and special comment: Since the nursery grounds are not known and the juveniles therefore not monitored, and as Greenland halibut is a slow-growing species, which first appears in the catches at age 5 , a possible recruitment failure will only be detected in the fishery some 5-10 years after it occurs.

Source of information: Report of the Northwestern Working Group, 29 April - 8 May 2002 (ICES CM 2002/ACFM:20).

### 3.2.6.a Overview

Stocks: There are two main commercial species of redfish in Subareas V, XII, and XIV, Sebastes marinus and $S$. mentella. In Division Va a small fishery has recently developed on the third redfish species, $S$. viviparus. There are indications that $S$. marinus includes a genetically distinct component "giant" $S$. marinus, with a different depth distribution than typical $S$. marinus. The stock structure of $S$. mentella is complex and uncertain, but there are indications that there may be at least "oceanic", "pelagic deep-sea", and "deepsea" stocks or stock components. Both the "oceanic" and "pelagic deep-sea" forms in the Irminger Sea are sometimes referred to as pelagic redfish, to differentiate them from the redfish associated with the slope and shelf areas. Thus the redfish fisheries in Subareas V, XII, and XIV operate on several stocks.

Of these stocks, typical S. marinus is mainly distributed in the shallower shelf areas, down to about 500 m depth.

The relationships of the various forms of S. mentella are complex, and not clearly differentiated. "Oceanic" and "pelagic deep-sea" forms of $S$. mentella both have pelagic distributions in the open Irminger Sea, and both can be found in depths from 100 to 1000 m . The "pelagic deep-sea" form is much more common than the "oceanic" form at depths greater than 500 m , and is exploited primarily by pelagic trawls. The "oceanic" form has its highest concentrations at depths less than 500 m , where it is exploited by the same fishing gears as
the "pelagic deep-sea" form. The "deep-sea" form has a distribution more closely associated with the continental shelf than either of the other forms, with a depth distribution from below 1000 m up to above 500 m , where it overlaps with typical $S$. marinus. The "deepsea" form is exploited primarily by otter board trawls, although other gears are also used.

Published genetic studies are inconclusive on whether these three forms of S. mentella are genetically distinct. Some types may even have additional substructure. However, in terms of distribution in the sea, there is substantial overlap of "pelagic deep-sea" and "oceanic" forms in the open sea. The distribution of the "pelagic deep-sea" form extends northward close enough to the continental shelf to overlap with the "deep-sea" form, and there may be exchange between the "oceanic" form and the "deep-sea" form at depths around 500 m near the continental slope as well. The figure below illustrates the complexities and uncertainties of the distributions of the species and forms of Sebastes in the Northwest area. Research continues to clarify the genetic relationships among the various forms, but regardless of future advances in that area, the morphological similarities among species and forms, and the overlapping distributions among them will continue to present difficulties for assessment and management of these resources.

Historic development of the fishery: Redfish in Division Va are mainly caught by trawlers using demersal and pelagic trawl. S. marinus is the predominant species down to depths of about 500 m , whereas deep-sea S. mentella contributes mostly to the catches at greater depths. The Icelandic fleet takes the major part of the catches, but vessels from Germany, UK, and Faroe Islands also fish in Division Va. In recent years the Icelandic fleet has also caught pelagic $S$. mentella in the deeper parts of Division Va using pelagic trawl.

In Division Vb , redfish are mainly caught by trawlers using demersal trawls. Down to about $500 \mathrm{~m}, \mathrm{~S}$. marinus is the most important redfish species, and pair-trawlers are the most important fleet. Deeper than about 500 m , redfish catches consist almost exclusively of deep-sea $S$. mentella taken mostly by otter-board trawlers larger than 1000 HP. The Faroese catches constitute more than 90\% of the redfish catches in this division. Otter-board trawlers from Germany and France occasionally target these stocks. The remainder of the total catches is mainly by-catch in other demersal fisheries.

Redfish catches taken by several countries in Subarea VI are considered to be mainly by-catch in demersal fisheries. These catches are negligible in comparison with redfish catches in Subareas V, XII, and XIV.

Catches in Subarea XII are mainly pelagic $S$. mentella and are taken by trawlers using pelagic trawls. At least 13 fleets have joined this fishery mainly from Russia, Germany, Iceland, Faroe Islands, and Norway.

In Subarea XIV both S. marinus and all S. mentella stocks are exploited. On the Greenland shelf and slopes, S. marinus dominates the trawl catches above 500 m , whereas deep-sea $S$. mentella dominates below 500 m . Most of the catches are taken by German freezer trawlers. In 1982 a pelagic trawl fishery started exploiting the oceanic $S$. mentella in the deeper parts of Subarea XIV. Since 1990 the main fleets are from Russia, Norway, Iceland, and Germany. In recent years, vessels from several other countries have joined this fishery, mainly outside the EEZs of Iceland and Greenland.

In Subareas Va, XII, and XIV, a pelagic fishery has developed at depths greater than 500 m to target $S$. mentella. In recent years, a substantial proportion of the pelagic $S$. mentella catch was taken below 500 m depth. For the first time, there was significant fishing effort extended from ICES Division XII into the NAFO Convention Area in the autumn of 2000 and 2001.

Landings: The total landings from the redfish stock complex (i.e. redfish in all Subareas) are given in Tables 3.2.6.a.1-5.

### 3.2.6.b $\quad$ Sebastes marinus in Subareas V, VI, XII, and XIV

State of stock/exploitation: The stock is considered to be outside safe biological limits. According to survey information, the stock in Division Va has fluctuated between $\mathbf{U}_{\mathrm{pa}}$ and $\mathbf{U}_{\text {lim }}$ since 1990 (Figure 3.2.6.b.1) and is presently slightly below $\mathbf{U}_{\mathrm{pa}}$. In Subarea XIV the German groundfish survey has shown an almost continuous decrease in biomass indices by more than $90 \%$ since 1986, and S. marinus at East-Greenland has been nearly depleted in the last decade (Figure 3.2.6.b.2). In Division Vb catches have declined since

1985 to a low level in recent years, which is also reflected in the Faroes summer survey (Figure 3.2.6.b.3). The strong 1990 year class has started to recruit to the fishery and should sustain the stock in the short to medium term. The surveys do no not indicate further strong year classes.

Management objectives: There is no explicit management objective for this stock.

Precautionary Approach reference points (unchanged since 1999):
ICES suggests that the relative state of the stock be assessed through survey CPUE index series (U).

| ICES considers that: | ICES proposes that: |
| :--- | :--- |
| $\mathbf{U}_{\text {lim }}=20 \%$ of highest observed survey index. | $\mathbf{U}_{\mathrm{pa}}$ be set at $60 \%$ of highest observed survey index. |

## Technical basis:

The basis for the calculation of the $\mathbf{U}_{\mathrm{pa}}$ is a survey index series starting in 1985 (Figure 3.2.6.b.1). Since 1990 the average $\mathbf{U}$ has been around half of $\mathbf{U}_{\text {max }}$. This has not resulted in any strong year classes compared to higher U's. A precautionary $\mathbf{U}_{\mathrm{pa}}$ is therefore proposed at $\mathbf{U}_{\text {max }} * 0.6$, corresponding to the U's associated with the most recent strong year class.

Advice on management: ICES advises that effort should be reduced by $\mathbf{2 5 \%}$, corresponding to catches not exceeding a total of 31000 t in ICES Divisions Va and Vb. As the fishable stock of $S$. marinus in Subarea XIV is depleted, ICES advises that there be no direct fishery for $S$. marinus in that Subarea. In order to rebuild the stock further in the near future fishing effort should not be allowed to expand on the incoming 1990 year class.

Relevant factors to be considered in management: Apart from the 1990 year class, no strong recruitment is expected for the stock for several years. The 1990 year class will have to support the fishery for several years and management must distribute the potential yield over many years.

Catch forecast for 2003: Catch in 2003 was estimated as a function of an average standardised CPUE series 19992001 and the estimated effort in 2001.

Comparison with previous assessment and advice: The survey index for 2001 is higher than that of 2000 due to the strong incoming 1990 year class. The advice is the same as last year.

Elaboration and special comment: S. marinus are mainly taken by trawlers in depths down to 500 m . In Division Va the catch is mainly taken by Icelandic trawlers, while in Division Vb Faroese trawlers predominate. In Subarea XIV the catches are mainly bycatch in shrimp fisheries. Total catches decreased almost continuously from 1983-1996, but have increased slightly since then. The decline occurred in all subareas. In order to reduce the catches of $S$. marinus in Division Va, an area closure was imposed in 1994 and the quotas have been reduced in the most recent years.

Icelandic survey data in Subarea Va, data from a German groundfish survey in Subarea XIV, and from the Faroes groundfish survey in Division Vb are used as indicators of the stock size in the respective areas.

## Estimated effort

 catch and suryey index rela

### 3.2.6.c <br> Deep-sea Sebastes mentella on the continental shelf in Subareas V, VI, and XIV

State of stock/exploitation: The stock as a whole is considered to be inside safe biological limits although status varies among regions. All CPUE indices show a substantial reduction from a high in the late 1980s, but from the mid-1990s the CPUE index from the Icelandic demersal fishery has remained relatively stable, slightly above $\mathbf{U}_{\mathrm{pa}}$. Since 1994 total catches have declined by over $50 \%$, although the decline is not completely the consequence of declining stock status. The catch in 2001 was the lowest catch since 1979. Some of the decline is due to catch restrictions which have substantially reduced effort since 1994.

Based on survey results the SSB of deep-sea $S$. mentella on the continental shelf in Subarea XIV remains severely depleted (Figure 3.2.6.c.2).

Management objectives: There is no explicit management objective for this stock. However, for any management objectives to meet precautionary criteria U should be greater than $\mathbf{U}_{\mathrm{pa}}$

Precautionary Approach reference points: (established in 1999)

| ICES considers that: | ICES proposes that: |
| :--- | :--- |
| The maximum index in the CPUE series from the <br> Icelandic commercial bottom trawl fishery be set as $\mathbf{U}_{\text {max }}$. | $\mathbf{U}_{\mathrm{pa}}=\mathbf{U}_{\max } / 2$. <br> $\mathbf{U}_{\mathrm{lim}}=\mathbf{U}_{\max } / 5$. |

## Technical basis:

The basis for the calculation of the $\mathbf{U}_{\mathrm{pa}}$ is a CPUE data series from the commercial fishery in Division Va starting in 1985 (Figure 3.2.6.c.1).

Advice on management: ICES advises that the effort should be kept low and no higher than the recent average. Accordingly, the catch for the total stock should be less than 30000 t . As the fishable stock of $S$. mentella in Subarea XIV is depleted ICES advises that there should be no direct fishery for $S$. mentella in that Subarea.

Relevant factors to be considered in management: The German surveys in East Greenland cover nursery grounds for $S$. mentella. A strong cohort from 1989 was observed in the survey in 1995 to 1998. That cohort has emigrated from the survey area and has started to contribute to the fisheries. There are no indications in the survey of more recent strong year classes.

The nursery grounds of $S$. mentella on the continental shelf in Subarea XIV probably supply recruits to both the pelagic redfish stocks in the Irminger Sea and the shelf stock in Divisions Va and Vb.

Catch forecast for 2003: Catch in 2003 was estimated as a function of an average standardised CPUE for 1999-2001 and the average effort in 1999-2001

Comparison with previous assessment and advice: The CPUE series, which is the basis for the advice has been revised. The revision did not alter the perception of the stock situation from last year's assessment. The effort in 2001 was about $40 \%$ lower than in previous years.

Elaboration and special comment: In Division Va deep-sea $S$. mentella are taken mainly by Icelandic
trawlers in depths greater than 500 m . In Division Vb the fishery is carried out mainly by Faroese trawlers, though some by-catch is taken by other countries fishing demersal species. In Subarea XIV the catch is taken largely by German freezer trawlers. The annual catches almost doubled in the early 1990s, but since then have decreased to the level of the 1980s. The increase was mainly caused by an increase in Division Va, both in the demersal and in a temporarily developed pelagic fishery, and by an increase in Subarea XIV in 1993-1994.

The advice for 2003 (of less than 30000 t) is for the entire stock.

Data and assessment: No data were available to make an analytical assessment. CPUE data are available from Icelandic trawlers in Division Va (1986-2001), the Faroese fishery in Division Vb (1985-2001), and from the German groundfish survey in Subarea XIV (19822001).

Figure 3.2.6.c. 1 CPUE, relative to 1986, from the Icelandic bottom trawl fishery for deep-sea S. mentella on the continental shelf, based on a GLIM model (a), which is the basis for the advice, and based on simple mean (b). The GLIM model shows the modelled development using GLIM including hauls where redfish deeper than 500 m compose $50 \%$ or more of the total catch in each haul. Simple mean means CPUE calculated on hauls where redfish deeper than 500 m compose $10 \%$ ( 50,70 and $90 \%$ lines are also shown) or more of the total catch in each haul. The horizontal line indicates $50 \%$ of $\mathbf{U}_{\text {max }}$.

 model.

### 3.2.6.d Pelagic fishery for Sebastes mentella in the Irminger Sea

The stock structure of pelagic redfish $S$. mentella in Subarea XII, Division Va, and Subarea XIV, and in the NAFO Convention Area remains generally uncertain. There is a difference in the depth and geographical distribution of the two pelagic redfish types, namely the 'oceanic S. mentella', mainly above 500 meters and southwesterly in the Irminger Sea, and the 'pelagic deep-sea $S$. mentella', mainly below 500 meters and northeasterly in the Irminger Sea. There are no indications that the pelagic $S$. mentella in the NAFO Convention Area are distinct from the stock(s) or components in the adjacent Irminger Sea.

State of stock/exploitation: The state of the stock is not precisely known. There are indications from acoustic surveys that the stock may have been larger in the early 1990s. Although variable, CPUE series from the commercial fisheries on both redfish types indicate no trend in the stocks since 1995. Biomass estimates from a survey in 2001 suggest a biomass in the order of 2 million tonnes, but this estimate is highly uncertain. Therefore it is not known if the current exploitation rate is above or below the $5 \%$ exploitation rate considered sustainable.

Management objectives: There is no explicit management objective for this stock.

Advice on management: The recent exploitation level seems not to have caused stock size reduction. For 2002 and 2003, ICES advises that TACs do not exceed current catch levels (including the NAFO Convention Area). The average catch in the last 5 years has been 119 thousand tonnes. In addition, ICES advises that management action should be taken to prevent a disproportional exploitation rate of any one component.

Relevant factors to be considered in management: Possible changes in the depth distribution of the two redfish types above and below 500 m combined with the differences in geographic coverage of acoustic surveys in different years ,mean that the acoustic biomass series cannot be interpreted as a consistent series showing relative changes in stock size. The stock structure for pelagic $S$. mentella is unknown. Fishing patterns after 1995 resulted in 2 almost distinct fishing grounds in terms of geographic distribution and trawling depth. In 2000 and 2001, substantial catches were taken from the pelagic $S$. mentella aggregations discovered recently in the NAFO Convention Area. There may be a relationship between the demersal deepsea $S$. mentella on the continental shelves of the Faroe Islands, Iceland, and Greenland and the pelagic $S$. mentella components in the Irminger Sea. This should be kept in mind in the management of these components.

Since this is a relatively new fishery on a long-lived, slow-growing species, ICES notes that monitoring of the stock is essential in order to keep track of biomass changes as they occur. Similarly, it is important to gather the information needed to evaluate the productivity of the stock. This includes information on recruitment, nursery areas, stock identification, and biomass estimation.

Nursery areas for both of the pelagic stock components are likely to be found at the continental slope off East Greenland. The juvenile redfish in these areas should, therefore, be protected and appropriate measures to reduce the by-catches in the shrimp fishery need to be taken.

Comparison with previous assessment and advice: The decline in the time-series of the acoustic survey has been the basis for the advice in past assessments. Less emphasis on the acoustic survey estimates has resulted in a change in the perception of stock trends. The decline in the acoustic estimators is no longer considered to represent stock decline only, but also changes in the availability of the $S$. mentella to the acoustical instruments. The assessment of the current state of the stock and the advice is based on standardized CPUE indices.

Elaboration and special comment: The pelagic fishery in the Irminger Sea is conducted only on the mature part (approximately $95 \%$ mature) of the stock. The fishery started in 1982. After decreasing from 1988-1991, mostly due to a reduction in Russian effort, landings increased. The increase in the catches from 1991-1996 is a direct consequence of increased fishing effort due to new fleets entering the fishery. However, the catches have been significantly lower during the last 5 years; at the same time the fishery has expanded into deeper water and the season has expanded from March to December.

The 2001 trawl-acoustic survey on pelagic redfish ( $S$. mentella) in the Irminger Sea and adjacent waters was carried out in June/July. Approximately 420000 square nautical miles were covered, which is the most extended coverage for acoustic assessment pelagic redfish in the Irminger Sea. The stock size measured with the acoustics was assessed to be about 715000 t at depths down to the deep-scattering layer or about 350 m . The acoustic survey results (shallower than 500 m ) indicate a stable stock situation size compared with the 1999 results. In 2001, as well as in 1999, the stock shallower than 500 m was observed more south-westerly and deeper than it has been during former acoustic surveys in the last decade.

By using information from trawl hauls biomass in the depth layers from 0-500 depth, including the layer
where the redfish that was mixed with the deepscattering layer, was estimated at about 1.1 mill. t. Such estimates are not directly comparable with the acoustic estimates shallower than 500 m depth and should be interpreted with care, due to their innovate nature. About 1.1 mill. t was estimated by using the information from the trawl hauls deeper than 500 m . At these depths, the densest concentrations were found in the NE part of the area (Figure 3.2.6.d.2). This method is still experimental and needs further development.

New survey information will be available after the June/July 2003 survey has been carried out.

Given the technical, seasonal, geographical, and depth changes of the fishing activities, the relevance of the estimated reduction in CPUE as indicator of stock abundance remains difficult to assess both above and below 500 m .

Data on maturity-at-length, and -at-weight and some age-reading experiments were available from both the survey and from the fishery. CPUE series are available for some fleets and as standardised series (Figures 3.2.6.d.1.a-c).

### 3.2.7 Icelandic summer-spawning herring (Division Va)

State of stock/exploitation: The stock is inside safe biological limits. The spawning stock biomass (SSB) in 2001 is estimated at 540000 t . The current fishing mortality of 0.2 is below the $\mathbf{F}_{\mathrm{pa}}$.

Management objectives: The practice has been to manage this stock at $\mathrm{F}=\mathbf{F}_{0.1}=\mathbf{F}_{\mathrm{pa}}$ for more than 20 years. However, no formal management strategy has been adopted.

Precautionary Approach reference points (unchanged since 1999):

| ICES considers that: | ICES proposed in 1998 that: |
| :--- | :--- |
| $\mathbf{B}_{\text {lim }}$ is 200000 t | $\mathbf{B}_{\mathrm{pa}}$ be set at 300000 t |
| $\mathbf{F}_{\text {lim }}$ not defined | $\mathbf{F}_{\mathrm{pa}}$ be set at 0.22 |

Technical basis:

| $\mathbf{B}_{\text {lim }}:$ SSB with a high probability of impaired recruitment | $\mathbf{B}_{\mathrm{pa}}: \mathbf{B}_{\mathrm{pa}}=\mathbf{B}_{\mathrm{lim}} \mathrm{e}^{1.645 \sigma} \sigma=0.25$ |
| :--- | :--- |
| $\mathbf{F}_{\text {lim }}:-$ | $\mathbf{F}_{\mathrm{pa}}: \mathbf{F}_{\mathrm{pa}}=\mathbf{F}_{0.1}=0.22$ (based on a weighted average) |

Advice on management: ICES recommends that this stock should be continued to be harvested at a maximum of fishing mortality rate $\mathrm{F}_{0.1}=\mathbf{0} .22$, corresponding to a maximum catch of $105000 t$ in the season 2002/2003.

Relevant factors to be considered in management: Icelandic TACs apply to 1 September to 31 August the following year.

Catch forecast for 2003: No catch options for 2003 are required.

Medium- and long-term projections: Medium-term forecasts in 1995 showed that there was a low probability that the current harvest strategy will reduce the stock to below $\mathbf{B}_{\text {pa. }}$.

Comparison with previous assessment and advice: There has been a general trend to overestimate SSB and underestimate F. VPA results were adjusted based on the retrospective bias.

Elaboration and special comment: The catches of Icelandic summer-spawning herring increased rapidly in the early 1960s due to the development of the purse seine fishery off the south coast of Iceland. This resulted in a rapidly increasing exploitation rate until the stock collapsed in the late 1960s. A fishing ban was
enforced during 1972-1975. Thereafter the catches have increased gradually to over 100000 t . Previously, the fleet consisted of multi-purpose vessels, mostly under 300 GRT, operating purse seines and driftnets. In recent years, larger vessels (up to 1500 GRT) have entered the fishery. These are a combination of purse seiners and pelagic trawlers operating in both the herring and capelin fisheries. In the past five seasons a considerable proportion of the catch has been taken with pelagic trawls.

Data and assessment: Analytical assessment based on catch data and surveys.

Source of information: Report of the Northern Pelagic and Blue Whiting Fisheries Working Group, 29 April - 8 May 2002 (ICES CM 2002/ACFM:19).

Yield and spawning biomass per Recruit F-reference points:

|  | Fish Mort <br> Ages 5-15 | Yield/R | SSB/R |

### 3.2.8 <br> Capelin in the Iceland-East Greenland-Jan Mayen area (Subareas V and XIV and Division IIa west of $5^{\circ} \mathrm{W}$ )

State of stock/exploitation: The stock is considered to be inside safe biological limits. SSB is highly variable due to dependency on only 2 age groups.

Management objectives: The fishery is managed according to a two-part harvest control rule which allows for a minimum spawning stock biomass of 400000 t by the end of the fishing season. ICES considers that the two-part harvest control rule is in accordance with the precautionary approach.

Advice on management: In order to ensure a spawning stock biomass of 400000 t in March 2003, ICES advises, in conformity with the harvest control rule that the preliminary TAC for the first half of the 2002/2003 season should not exceed 690000 t. This is two thirds of the total catch of 1040000 t predicted for the whole season. ICES advises that the data from the surveys in November 2002 and/or January-February 2003 be used when the final TAC is set for the 2002/2003 season. ICES advises that, while the 2002 summer/autumn season could be opened on 20 June, areas of high juvenile abundance should be closed to commercial fishery in order to prevent harvesting a high proportion of juveniles.

Relevant factors to be considered in management: In recent years, large capelin have dominated the catches in July and the first half of August. From the second half of August, the average weight in the catches has often declined drastically due to the presence of juvenile fish and not increased again until late autumn.

The spawning stock fell below the minimum safe level of 400000 t in the 1989/90 and 1990/91 seasons. The stock recovered quickly due to good recruitment and appears to be fairly strong at present.

Catch forecast for 2003: The basis for the forecast is acoustic surveys and a regression-based prediction model. The model predicts a catch of 77.4 billion maturing 2 -group capelin and 18.2 billion maturing 3group capelin in 2002/2003. When a predicted catch of 1040000 t is taken in the 2002/2003 season, it is expected that at least 400000 t remains to spawn.

Elaboration and special comment: The fishery is mainly an industrial fishery based on maturing capelin, i.e., the 2 - and 3 -group in the autumn, which spawn at ages 3 and 4 in March of the following year. After being low in the 1989/90 and 1990/91 seasons, catches have increased and have in recent years been more than 1 million t . A record catch of 1571000 t was taken during the 1996/97 fishing season.

Preliminary TAC computations are based on a method which involves the use of 1-group $\left(N_{l}\right)$ indices from the October-November survey for predicting the mature 2group ( $N_{2 \text { mat }}$ ) in the following year. The total 2-group $\left(N_{2}\right.$ tot $)$ abundance from the same survey and the relationship between maturation ratios and year class abundance are used for predicting numbers of capelin in the 3-group ( $N_{3 \text { mat }}$ ).

Since 1989, the weight at age shows a significant negative correlation with the adult stock in number. A regression-based predictive model using data from the period 1989-1997 results in predicted mean weights of 16.2 and 22.6 g for age groups 2 and 3 respectively.

The stock size is assessed using trawl/acoustic survey data.

Source of information: Report of the Northern Pelagic and Blue Whiting Fisheries Working Group, 29 April - 8 May 2002 (ICES CM 2002/ACFM:19).

*Preliminary

## NEAFC requested information on:

a) Review the stock situation and its advice for pelagic redfish in the Irminger Sea for 2002 at the May 2002 ACFM meeting.
b) submit new information on stock identity of the components of redfish such as "pelagic deep-sea" Sebastes mentella, "oceanic" Sebastes mentella fished in the pelagic fisheries, and the "deep-sea" Sebastes mentella fished in demersal fisheries on the continental shelf and slope;
c) provide information on the horizontal and vertical distribution of pelagic redfish stock components and fisheries in the Irminger Sea and adjacent waters as well as seasonal and interannual changes in distribution. Information on the vertical distribution should allow NEAFC to further consider the appropriateness of separate management measures for different geographical areas/seasons.

The request a) is addressed in the ACFM report, Section 3.2.6.d.

## Request b): On further information on stock identity of redfish

An extensive discussion of the problem was made at NEAFC's request last year (Section 3.2.9 in the 2001 ACFM report). The request is also addressed as part of the introduction section 3.2.6.a in this year's report.

Some recent studies on genetics, biological markers, and fish distribution were presented to the Working Group in 2002. ICES considers that interpretations of the evidence on stock structure are still diverging and that individual indicators are inconclusive. Therefore the stock structure remains uncertain. Further studies are in progress.

Request c): Update information on the development of the pelagic fishery for redfish with respect to seasonal and area distribution to allow NEAFC to further consider the appropriateness of separate management measures for different geographical areas/seasons.

Observations indicate that since 1996 a) the fisheries in the Northeastern area in the first half of the year are occurring at depths deeper than 500 m and catching larger fish, and b) the fisheries in the Southwestern area in the second half of the year are mainly occurring at depths shallower than 500 m catching smaller fish. In last year's report there was a detailed description of the fishery. Below is an update to this information.

The geographical distribution of the catches by periods and years since 1995 is given in Figure 3.2.6.a.2. The fishery of these four nations (Germany (1995-2001), Iceland (1989-2001), Norway (1995-2001), Russia (1999-2000), and Greenland (1999-2001)) indicate that there was a similar pattern in the fishery since 1996. Fishing usually started in early April and up to the end of June it was prosecuted in areas east of $32^{\circ} \mathrm{W}$ and north of $61^{\circ} \mathrm{N}$. In July and August, the fleet moves about $400-500$ nautical miles to areas south of $60^{\circ} \mathrm{N}$ and west of about $34^{\circ} \mathrm{W}$, where the fishery continues until October. There is very little fishing activity from November until late March. Figure 3.2.6.a. 3 gives the locations of part of the Spanish activity in the Irminger Sea, and it shows that they had a similar pattern in 2000 and 2001 as the above-mentioned fleets. The same applies for the Russian fleet in 2001 (Figure 3.2.6.a.4). In the third quarter of the year the fishing has, in general, moved towards the southern part of the area, fishing mostly at depths shallower than 500 m , within Subarea XII as well as in the NAFO convention area, both outside and inside the Greenlandic EEZ. However, it is important to note that the described fishing pattern of the fleet changed significantly around 1995, mainly in terms of area and depth expansion. The changes in the fishing pattern as described above does not necessarily reflect changes in stock distribution, maybe due to commercial reasons.

Although the information on fishing depth is incomplete, except for the Icelandic, Faroese, and the Greenlandic fisheries, the general pattern is that the fishing in the first and second quarter of the year is mostly conducted deeper than 500 m . Further, although there are no haul-by-haul data available for the German catches, the available information shows that the fishery in the first two quarters was characterised by a fishery deeper than 450 m , and at shallower depths during the third and fourth quarters in 1995-2001. There is a similar pattern in the Spanish fishery. They were fishing deeper than 500 m in the second quarter of the year, and in the third quarter fishery continued at depths shallower than 500 m . The Greenland vessel participating in this fishery also reported all its catches taken above 400 m after July, and showed the same pattern as the Icelandic fleet in the first 2 quarters of the year.

Over $95 \%$ of all the fish caught in the pelagic redfish fishery are mature. The redfish caught in the Southwestern area are generally smaller than the fish caught in the Northeastern area (Figure 3.2.6.a.5), the dominant length classes being $33-38 \mathrm{~cm}$ in the Southwestern area, and $35-45 \mathrm{~cm}$ in the Northeastern area.

As has been reported in earlier reports of the Working Group, Iceland has classified its pelagic catches between oceanic and pelagic deep-sea redfish according to a contentious method. The results of this
classification have shown that the proportion of fish classified as oceanic-type redfish has been very low during recent years, and only about $5 \%$ of the Icelandic catches were classified as oceanic type. The Icelandic fishery prior to 2001 was mostly concentrated on the pelagic deepsea fishery in the first half of the year in the Northeastern area. In 2001, the percentage of the oceanic type increased to about $1 / 3$ of its quota, this being largely a result of increased effort in the Southwestern fishing area at depths shallower than 400 m . The increase in 2001 is due to the effort regulations in the fishery. Based on the samples, the results also
indicate that shallower than $500-600 \mathrm{~m}$ depth, the proportion "oceanic" is between $85-100 \%$, as the proportion deeper than 600 m is usually between 0 $20 \%$.

ICES recommends that NEAFC requests all nations participating in the pelagic redfish fishery to provide ICES with information on the trawling depth (headline depth for each haul as a log-book data), so ICES can have more detailed description of the fishery by season and areas as a basis for giving its advice on the resource.

### 3.3 Demersal stocks at the Faroe Islands (Division Vb)

### 3.3.1 Overview

The fisheries and management measures: In 1977 an EEZ was introduced in the Faroe area. The demersal fishery by foreign nations has since decreased and Faroese vessels now take most of the catches. The fishery may be considered a multi-fleet and multispecies fishery. The longliners fish mainly cod and haddock; in addition, some longliners fish in deep water for ling and tusk. Most of the trawlers fish cod, haddock, and saithe, while some large trawlers fish in deeper waters for redfish, blue ling, Greenland halibut, and occasionally grenadier and black scabbardfish. The jiggers fish mainly saithe and cod. Recently, gill net fisheries for Greenland halibut and anglerfish and a directed pair trawler fishery for Argentines have been introduced. The total demersal catches decreased from 120000 t in 1985 to 65000 t in 1993, but have since increased again to about 100000 t in 1997-1999; the 2001 demersal catch was above 120000 t . The decrease was mainly due to lower catches of cod, haddock, and saithe. The cod catches (Faroe Plateau cod and Faroe Bank cod combined) increased considerably from 6000 t in 1993 to more than 42000 t in 1996, but declined thereafter to around 20000 t in 1999; the 2001 catches were 31000 t . The catches of haddock also increased considerably from 4000 t in 1993 to 22000 t in 1998, but have since decreased to 16000 t in 2001. The catches of saithe decreased from 33000 t in 1993-1994 to 20000 t in 1996, but have since increased again to 52000 t in 2001.

During the 1980s and 1990s the Faroese authorities have regulated the fishery and the investment in fishing vessels. In 1987 a system of fishing licences was introduced. The demersal fishery at the Faroe Islands has been regulated by technical measures (minimum mesh sizes and closed areas). In order to protect juveniles and young fish, fishing is temporarily prohibited in areas where the number of small cod, haddock, and saithe exceeds $30 \%$ in the catches; after $1-2$ weeks the areas are again opened for fishing. A reduction of effort has been attempted through banning of new licences and buy-back of old licences.

A new quota system, based on individual quotas, was introduced in 1994. The fishing year started on 1 September and ended on 31 August the following year. The aim of the quota system was, through restrictive TACs for the period 1994-1998, to increase the SSBs of Faroe Plateau cod and haddock to 52000 t and 40000 t , respectively. The TAC for saithe was set higher than recommended scientifically. It should be noted that cod, haddock and saithe are caught in a mixed fishery and any management measure should account for this. Species under the quota system were Faroe Plateau cod, haddock, saithe, redfish, and Faroe Bank cod.

The catch quota management system introduced in the Faroese fisheries in 1994 was met with considerable criticism and resulted in discarding and in misreportings of substantial portions of the catches. Reorganisation of enforcement and control did not solve the problems. As a result of the dissatisfaction with the catch quota management system, the Faroese Parliament discontinued the system as from 31 May 1996. In close cooperation with the fishing industry, the Faroese government has developed a new system based on individual transferable effort quotas in days within fleet categories. The new system entered into force on 1 June 1996. The fishing year from 1 September to 31 August, as introduced under the catch quota system, has been maintained.

The individual transferable effort quotas apply to: 1) the longliners less than 100 GRT, the jiggers, and the single trawlers less than 400 HP , 2) the pair trawlers and 3) the longliners greater than 100 GRT. The single trawlers greater than 400 HP do not have effort limitations, but they are not allowed to fish within the 12 nautical mile limit, and the areas closed to them, as well as to the pair trawlers, have increased in area and time. Their catch of cod and haddock is limited by maximum by-catch allocation. The single trawlers less than 400 HP are given special licences to fish inside 12 nautical miles with a by-catch allocation of $30 \% \operatorname{cod}$ and $10 \%$ haddock. In addition, they are obliged to use sorting devices in their trawls. One fishing day by longliners less than 100 GRT is considered equivalent to two fishing days for jiggers in the same gear category. Longliners less than 100 GRT could therefore double their allocation by converting to jigging. Table 3.3.1.1 shows the number of fishing days used by fleet category for 1985-1995 and 1998-2001 and Table 3.3.1.2 shows the number of allocated days inside the outer thick line in Figure 3.3.1.1. Holders of individual transferable effort quotas who fish outside this line can fish for 3 days for each day allocated inside the line. Trawlers are generally not allowed to fish inside the 12 nautical mile limit. Inside the innermost thick line only longliners less than 100 GRT and jiggers less than 100 GRT are allowed to fish. The Faroe Bank shallower than 200 m is closed to trawling.

The effort quotas are transferable within gear categories. The allocations of number of fishing days by fleet categories was made such that together with other regulations of the fishery they should result in average fishing mortalities on each of the 3 stocks of 0.45 , corresponding to average annual catches of $33 \%$ of the exploitable stocks in numbers. Built into the system is also an assumption that the day system is selfregulatory, because the fishery will move between stocks according to the relative availability of each of them and no stock will be overexploited.

In addition to the number of days allocated in the law, it is also stated in the law what percentage of total catches of cod, haddock, saithe, and redfish each fleet category
on average is allowed to fish. These percentages are as follows:

| Fleet category | Cod | Haddock | Saithe | Redfish |
| :--- | :---: | :---: | :---: | ---: |
|  |  |  |  |  |
| Longliners < 110GRT, jiggers, single trawl. $<400 \mathrm{HP}$ | $51 \%$ | $58 \%$ | $17.5 \%$ | $1 \%$ |
| Longliners $>110 \mathrm{GRT}$ | $23 \%$ | $28 \%$ |  |  |
| Pairtrawlers | $21 \%$ | $10.25 \%$ | $69 \%$ | $8.5 \%$ |
| Single trawlers > 400 HP | $4 \%$ | $1.75 \%$ | $13 \%$ | $90.5 \%$ |
| Others | $1 \%$ | $2 \%$ | $0.5 \%$ | $0.5 \%$ |

Technical measures such as area closures during the spawning periods, to protect juveniles and young fish, and mesh size regulations as mentioned above are still in effect.

The marine environment: The waters around the Faroe Islands are in the upper 500 m dominated by the North Atlantic current, which to the north of the islands meets the East Icelandic current. Clockwise current systems create retention areas on the Faroe Plateau (Faroe shelf) and on the Faroe Bank. In deeper waters to the north and east is deep Norwegian Sea water, and to the south and west is Atlantic water. From the late 1980s the intensity of the North Atlantic current passing the Faroe area decreased, but it has increased again in the most recent years. The productivity of the Faroese waters was very low in the late 1980s and early 1990s. This applies also to the recruitment of many fish stocks, and the growth of the fish was poor as well. From 1992 onwards the conditions have returned to more normal values, which is also reflected in the fish landings. There has been observed a very clear relationship, from
primary production to the higher trophic levels (including fish and seabirds), in the Faroe shelf ecosystem, and all trophic levels seem to respond quickly to variability in primary production in the ecosystem.

State of stocks: As a result of the combined effect of poor recruitment in the last decade and high fishing effort, the SSBs of Faroe Plateau cod and Faroe haddock were reduced to low levels. In the period 1993-1995 ICES considered them to be well below minimum biologically acceptable levels and consequently advised no fishing. Both stocks have since increased due to improved recruitment and growth with SSB above the precautionary SSB levels ( $\mathbf{B}_{\mathrm{pa}}$ ). The fishing mortality on both Faroe Plateau cod and Faroe haddock has been estimated to be above the precautionary level ( $\mathbf{F}_{\mathrm{pa}}$ ) since 1996. The Faroe Bank cod stock seems to be at or slightly above average. The SSB of Faroe saithe has been increasing from the record low in 1992 to above the $\mathbf{B}_{\mathrm{pa}}$ in 1998-2001. The fishing mortality is above the precautionary level $\left(\mathbf{F}_{\mathrm{pa}}\right)$.

Table 3.3.1.1 Number of fishing days used by various fleet groups in Vb1 1985-1995 and 1998-2001. For other fleets there are no effort limitations. Catches of saithe and redfish are regulated by by-catch percentages given in the text. In addition there are special fisheries regulated by licenses. (This is the real number of days fishing not affected by doubling or tripling of davs by changing areas/gears).

Fishing area regulations in Division Vb . Allocation of fishing days applies to the area inside the outer thick line on the Faroe Plateau. Holders of effort quotas who fish outside this line can triple their numbers of days. Longliners larger than 110 GRT are not allowed to fish inside the inner thick line on the Faroe Plateau. If longliners change from longline to jigging, they can double their number of days. The Faroe Bank shallower than 200 m depths ( a , aa) is regulated separate from the Faroe Plateau. It is closed to trawling and the longline fishery is regulated by individual day quotas.

### 3.3.2

Cod

### 3.3.2.a Faroe Plateau cod (Subdivision $\mathbf{V b}_{1}$ )

State of stock/exploitation: The stock is harvested outside safe biological limits. The spawning biomass in 2001 is estimated to be above $\mathbf{B}_{\mathrm{pa}}$, but the 2001 fishing mortality is well above $\mathbf{F}_{\text {pa }}$ and above $\mathbf{F}_{\text {lim. }}$. The 1998 year class is of average strength and the 1999 year class appears to be very strong.

Management objectives: The effort management system implemented in the Faroese demersal fisheries in Division Vb since 1996 aims at harvesting on average $33 \%$ in numbers of the cod exploitable stock. This translates into an average F of 0.45 . This is inconsistent with the precautionary approach with the $\mathbf{F}_{\mathrm{pa}}$ of 0.35 .

Precautionary Approach reference points (established in 1998).

| ICES considers that: | ICES proposes that: |
| :--- | :--- |
| $\mathbf{B}_{\text {lim }}$ is 21000 t , the lowest observed biomass | $\mathbf{B}_{\mathrm{pa}}$ be set at 40000 t |
| $\mathbf{F}_{\text {lim }}$ is 0.68 | $\mathbf{F}_{\mathrm{pa}}$ be set at 0.35 |

## Technical basis:

| $\mathbf{B}_{\text {lim: }}: \mathbf{B}_{\text {lim }}=\mathbf{B}_{\text {loss }}(98)$ | $\mathbf{B}_{\mathrm{pa}}: \mathbf{B}_{\mathrm{pa}}=\mathbf{B}_{\text {lim }} \mathrm{e}^{1.645 \sigma}$, assuming a $\sigma$ of about 0.40 to <br> account for the relatively large uncertainties in the <br> assessment |
| :--- | :--- |
| $\mathbf{F}_{\text {lim: }}: \mathbf{F}_{\text {lim }}=\mathbf{F}_{\mathrm{pa}} \mathrm{e}^{1.645 \sigma}$, assuming a $\sigma$ of about 0.40 to <br> account for the relatively large uncertainties in the <br> assessment | $\mathbf{F}_{\mathrm{pa}}:$ Close to $\mathbf{F}_{\text {max }}(0.34)$ and $\mathbf{F}_{\text {med }}(0.38)$ values from 1998 <br> assessment |

Advice on management: ICES advises a reduction in fishing mortality to below $\mathrm{F}_{\mathrm{pa}}(0.35)$, corresponding to an effort reduction of $\mathbf{5 0 \%}$. If this cannot be done in one year then as a first step, the fishing mortality in 2003 should be reduced by at least $35 \%$ in accordance with the fishing mortality advised (0.46) in 2001.

Relevant factors to be considered in management: Current fishing mortality is far above the $\mathbf{F}_{\mathrm{pa}}$, but the basis for $\mathbf{F}_{\mathrm{pa}}$ is under revision. A reduction in fishing mortality to $\mathbf{F}_{\mathrm{pa}}$ corresponds to landings of less than 23000 t , and a $35 \%$ reduction in fishing mortality in 2003 corresponds to landings of less than 28000 t .

Close monitoring should be carried out in order to evaluate the effect of the effort regulation, in particular the possible changes in catchability and target species. Effort regulation systems may lead to investment aimed at increasing fishing efficiency in order to obtain the greatest benefits from the effort allocated. Management authorities should monitor vessel characteristics in order to evaluate potential increases in capacity as a result of technological changes.

Catch forecast for 2003:
Basis: $\mathrm{F}(2002)=\mathbf{F}_{\mathrm{sq}}=\mathrm{F}(2001)=0.71$; Landings
$(2002)=41.9 ; \operatorname{SSB}(2002)=64 ; \operatorname{SSB}(2003)=74$

| $\mathrm{F}(2003)$ | Basis | Landings <br> $(2003)$ | SSB (2004) |
| :---: | :---: | :---: | :---: |
| 0.35 | $0.5 * \mathbf{F}_{\mathrm{sq}}=\mathbf{F}_{\mathrm{pa}}$ | 22.8 | 82 |
| 0.43 | $0.6 * \mathbf{F}_{\mathrm{sq}}$ | 26.6 | 78 |
| 0.46 | $0.65 * \mathbf{F}_{\mathrm{qq}}$ | 28.5 | 76 |
| 0.49 | $0.7 * \mathbf{F}_{\mathrm{sq}}$ | 30.3 | 74 |
| 0.53 | $0.75 * \mathbf{F}_{\mathrm{sq}}$ | 32.1 | 72 |
| 0.57 | $0.8 * \mathbf{F}_{\mathrm{sq}}$ | 33.8 | 71 |
| 0.71 | $\mathbf{F}_{\mathrm{sq}}$ | 40.3 | 64 |
| 0.85 | $1.2 * \mathbf{F}_{\mathrm{sq}}$ | 46.1 | 58 |

(Weights in '000 t)
Shaded scenarios considered inconsistent with the precautionary approach.
The status quo F assumes the same fleet allocation as in 2001.

Medium- and long-term projections: No medium-term projection was made in current assessment.

Comparison with previous assessment and advice: A summer groundfish survey was used as the only tuning series in this year's assessment, i.e. the commercial tuning series used last year were not used. The estimates of the 1997 and 1998 year classes in the current assessment are lower than in last year's assessment, The 1999 year class appears to be very strong. No major changes have occurred in the perception of the spawning stock biomass. The fishing mortalities 1997-1999 are estimated to be higher, and the 2000 fishing mortality lower, compared to last year's assessment.

Elaboration and special comment: There are indications that environmental conditions (food availability) are determining cod production. The growth rate of fish in the stock has shown a declining trend over the last three decades, with a short-term increase in the mid-1990s. After a drop in 1998 the growth rate has increased again.

Cod are taken in a mixed demersal fishery which was initially international. Following the declaration of EEZs in 1977, the fishery became largely Faroese. Most of the vessels involved are trawlers and longliners.

The survey database is being re-constructed and one summer groundfish survey was available this year. Next
year it is expected that a part of the spring groundfish survey will be available, and the two survey indices will be evaluated for inclusion in the assessment next year.

Previous medium-term projections and spawners per recruit calculations suggest that the proposed $\mathbf{F}_{\mathrm{pa}}$ may be too conservative. This will be more thoroughly evaluated in the 2003 assessment.

Data and assessment: In this analytical assessment catch-at-age data are tuned with a summer groundfish series.

Source of information: Report of the Northwestern Working Group, 29 April - 8 May 2002 (ICES CM 2002/ACFM:20).

Yield and spawning biomass per Recruit F-reference points:

### 3.3.2.b Faroe Bank cod (Subdivision $\mathbf{V b}_{2}$ )

State of stock/exploitation: Although the stock biomass is not known, it appears to be above average based on survey indices. The surveys indicate a steep increase of the stock in 1996-1998 compared with previous years, followed by a decline to average biomass in 1999-2000 (Figure 3.3.2.b.1). In 2001, the stock seems to have increased again and length distributions suggest strong incoming year classes. The 2002 survey estimate remained high, although slightly lower than in 2001. The ratio of landings to the survey CPUE index provides an exploitation ratio (Figure 3.3.2.b.2), which can be used as a proxy to relative changes in fishing mortality. The results suggest that fishing mortality has decreased over time and is now close to the lowest observed.

Management objectives: There are no explicit management objectives for this stock and biological reference points have not been established.

Advice on management: ICES advises that fishing effort on the Faroe Bank should not exceed that exerted annually since 1996 .

Comparison with previous assessment and advice: The advice is similar to last year's.

Relevant factors to be considered in management: The landing estimates are uncertain because since 1996 the vessels are allowed to fish both on the Plateau and on Faroe Bank during the same trip, making it difficult to assign landings to area. Given the relative size of the two fisheries, this causes greater uncertainty regarding catches for Faroe Bank cod than for Faroe Plateau cod, but the magnitude remains unquantified for both. The ability to provide advice depends on the reliability of input data. Because the cod landings from Faroe Bank are not known, it is not possible to provide catch advice on management. If the fishery management agency intends to manage the two fisheries to protect the productive capacity of each individual unit, then it is necessary to monitor and regulate the catch removed from each stock.

Elaboration and special comment: An analytic assessment was attempted at the 2000 Working Group meeting. ACFM concluded that analytic assessment is not considered appropriate until reliable coverage of the total catch-at-age can be obtained. Survey indices in the spring 2001 may be misleading, since the total catch was dominated by one very large catch.

Source of information: Report of the Northwestern Working Group, 29 April - 8 May 2002 (ICES CM 2000/ACFM:20).

## Faroe Bank cod

Figure 3.3.2.b. 1 Faroe Bank (Subdivision Vb2) COD. Catch per unit effort in the spring and autumn groundfish survey.

## Faroe Bank cod

Figure 3.3.2.b. 2 Faroe Bank (Subdivision Vb2) COD. Exploitation ratio.

### 3.3.3 Faroe haddock (Division Vb)

State of stock/exploitation: The stock is harvested outside safe biological limits. SSB in 2002 is estimated to be slightly above $\mathbf{B}_{\mathrm{pa}}$. Fishing mortality in 2001 is estimated to be above $\mathbf{F}_{\mathrm{pa}}$. The SSB increased significantly in 1996-1998 due to the recruitment of two strong year classes. The subsequent year classes have been below average except for the 1999 year class, which is estimated to be above average.

Management objectives: The effort management system implemented in the Faroese demersal fisheries in Division Vb since 1996 aims at harvesting on average $33 \%$ of the haddock exploitable stock. This translates into an average F of 0.45 , higher than the proposed $\mathbf{F}_{\mathrm{pa}}$ of 0.25 and higher than the $\mathbf{F}_{\text {lim }}=0.40$. The harvest regime is therefore expected to maintain fishing mortalities in excess of $\mathbf{F}_{\text {lim }}$. ICES considers this regime as inconsistent with the Precautionary Approach.

Precautionary Approach reference points (unchanged since 1999):

| ICES considers that: | ICES proposed that: |
| :--- | :--- |
| $\mathbf{B}_{\text {lim }}$ is 40000 t | $\mathbf{B}_{\mathrm{pa}}$ be set at 55000 t |
| $\mathbf{F}_{\text {lim }}$ is 0.40 | $\mathbf{F}_{\mathrm{pa}}$ be set at 0.25 |

Technical basis:

| $\mathbf{B}_{\text {lim }}:$ Former MBAL | $\mathbf{B}_{\mathrm{p} a}: 2$ st. dev. above $\mathbf{B}_{\text {lim }}$, but reduced based on inspection <br> of the SSB-R scatter plot |
| :--- | :--- |
| $\mathbf{F}_{\text {lim }}: 2 *$ std. dev. above $\mathbf{F}_{\mathrm{pa}}$ | $\mathbf{F}_{\mathrm{pa}}: \mathbf{F}_{\mathrm{med}}(1998)=0.25$ |

## Advice on management: ICES advises a reduction in

 fishing mortality to below $\mathrm{F}_{\mathrm{pa}}(0.25)$, corresponding to an effort reduction of about $35 \%$.Relevant factors to be considered in management: A $35 \%$ percent reduction in fishing mortality in 2003 corresponds to landings of no more than 12000 t . Under the present management regime this can be achieved by reducing the overall directed effort at haddock and/or by establishing area closures for all gears capable of catching haddock. The effect of the effort regulation should be closely monitored, in particular the possible changes in catchability and target species. Haddock are taken in a mixed fishery together with saithe and cod.

## Catch forecast for 2003:

Basis: $\mathrm{F}(2002)=\mathrm{F}_{\mathrm{sq}}=\mathrm{F}(2001)=0.38$; Landings (2002) $=$ 21; $\operatorname{SSB}(2003)=57$

| $\mathrm{F}(2003$ <br> onwards) | Basis | Landings <br> $(2003)$ | SSB (2004) |
| :---: | :---: | :---: | :---: |
| 0.19 | $0.5 * \mathrm{~F}_{\mathrm{sq}}$ | 9 | 58 |
| 0.25 | $\mathbf{F}_{\mathrm{pa}}\left(0.66 \mathrm{~F}_{\mathrm{sq}}\right.$ | 12 | 55 |
| 0,29 | $0.75 \mathrm{~F}_{\mathrm{sq}}$ | 14 | 54 |
| 0.30 | $0.8 \mathrm{~F}_{\mathrm{sq}}$ | 14 | 53 |
| 0.38 | $1.0 \mathrm{~F}_{\mathrm{sq}}$ | 18 | 50 |
| 0.45 | $\mathrm{~F}_{\text {lim }}$ | 20 | 46 |

Weights in ${ }^{6} 000 \mathrm{t}$.
Shaded scenarios considered inconsistent with the precautionary approach.

## Comparison with previous assessment and advice:

The present assessment is highly uncertain, to a large extent because of conflicting signals in the various sources of information. The stock is now estimated
above $\mathbf{B}_{\mathrm{pa}}$ due to a combination of lower estimates of fishing mortality and the strong incoming 1999 year class. In 2001, due to lack of reliable recruitment estimates, geometric mean recruitment was assumed for age 2 in the assessment year and in the projections. Those year classes are presently estimated to be considerably higher. The assessment this year was tuned with a survey as opposed to the commercial CPUE indices last year.

Elaboration and special comment: The estimate of the recruiting year classes has improved, as survey indices now are available in the assessment.

The mean weights-at-age, which have been decreasing since the middle of the 1990s, have now increased again for most ages.

Haddock is mainly fished by longliners and pair-trawlers. At present there are closed areas to trawling, and this combined with the large minimum mesh size in the codend ( 145 mm ) effectively reduces catches of juvenile and young haddock in trawl fisheries, whereas this is not the case for longliners.

Data and Assessment: The analytical assessment was performed using a survey index. Recruitment estimates were available from survey.

### 3.3.4 Faroe saithe (Division Vb)

State of stock/exploitation: The stock is harvested outside safe biological limits. SSB is above $\mathbf{B}_{\mathrm{pa}}$. The 1996 year class is the highest on record. Also the 1997 year class is good.

Management objectives: The effort management system implemented in the Faeroese demersal fisheries
(Division Vb ) since 1996 aims at harvesting on average $33 \%$ of the saithe stock in numbers. This translates into an average F of 0.45 , higher than $\mathbf{F}_{\mathrm{pa}}$ of 0.28 and even above $\mathbf{F}_{\text {lim }}$ of 0.4. ICES considers this regime to be inconsistent with the precautionary approach.

Precautionary Approach reference points (unchanged since 1999):

| ICES considers that: | ICES proposes that: |
| :--- | :--- |
| $\mathbf{B}_{\text {lim }}$ is 60000 t | $\mathbf{B}_{\mathrm{pa}}$ be set at 85000 t |
| $\mathbf{F}_{\text {lim }}$ is 0.40 | $\mathbf{F}_{\mathrm{pa}}$ be set at 0.28 |

## Technical basis:

| $\mathbf{B}_{\text {lim }}:$ lowest observed SSB | $\mathbf{B}_{\mathrm{pa}}:$ former MBAL |
| :--- | :--- |
| $\mathbf{F}_{\text {lim }}:$ consistent with $\mathbf{B}_{\text {lim }}$ of 60000 t | $\mathbf{F}_{\mathrm{pa}}:$ consistent with $\mathbf{F}_{\text {lim }}$ and $\mathbf{F}_{\mathrm{med}}$ |

Advice on management: ICES advises that fishing effort in 2003 be reduced to correspond to fishing mortality below $\mathrm{F}_{\mathrm{pa}}=0.28$, corresponding to an effort reduction of about $15 \%$. Current practice under the effort management system, to increase the number of fishing days allowed when moving into deeper waters, should be suspended until fishing mortality has decreased such that saithe is harvested within safe biological limits. The present spawning closures should be maintained.

Relevant factors to be considered in management: In recent years, fishing mortality in the last assessment year has consistently been overestimated, and the SSB underestimated.

The advised reduction in fishing mortality to below $\mathbf{F}_{\mathrm{pa}}$ $=0.28$ corresponds to landings less than 47000 t . The effect of the effort regulations should be closely monitored, in particular the possible changes in catchability and target species. In addition, it should be noted that saithe are partly caught in a mixed trawl fishery together with haddock and cod. Hence management measures taken in 2001/2002 for cod and haddock should also ensure protection for the saithe stock.

Catch forecast for 2003:
Basis: $\mathrm{F}(2002)=\mathbf{F}_{\mathrm{sq}}=\mathrm{F}(1999-2001)=0.324$; Landings $(2002)=53.3 ; \operatorname{SSB}(2003)=150.7$

(Weights in '000 t)
Shaded scenarios considered inconsistent with the precautionary approach.

Medium- and long-term projections: Medium-term projections were included in the 2001 advice.

Comparison with previous assessment and advice: SSB for 2001 is now estimated about $55 \%$ above the estimate provided in 2001. This partly reflects the uncertainty in the assessment and is partly caused by the upward revision of the estimate of the strength of the 1996 year class.

Elaboration and special comment: Saithe are predominantly taken in a mixed trawl fishery although some targeting occurs, in which case by-catches of other demersal species are small. The fishery was originally international, but for all practical purposes saithe has been fished only by Faroese vessels since the introduction of the 200 nm EEZ in 1977. The principal fleet consisting of large pair trawlers with engines larger than 1000 HP accounted for $60 \%$ of the catches in 1994-2001. In the same period the smaller pair trawlers ( $<1000 \mathrm{HP}$ ) caught $20 \%$, jiggers $9 \%$, and large single trawlers $9 \%$. All other vessels had only small catches of saithe as by-catch. Growth rates have increased from the low level observed in 1990-1991 to higher values in 1994-1996 and have decreased again since 1997.

The assessment was tuned with commercial pair trawler catch and effort data from logbooks. No recruitment indices are available.

Data and assessment: Catch-at-age and CPUE using same settings as last year.

## 3.4

 Stocks in the Skagerrak and Kattegat (Division IIIa)
### 3.4.1 Overview

## Description of fisheries

The fleets operating in the Skagerrak and Kattegat (Division IIIa) include vessels targeting species for human consumption as well as vessels engaged in fisheries for reduction purposes. The human consumption fleets are diverse, including gillnetters and Danish seiners exploiting flatfish and cod and demersal trawlers involved in various human consumption fisheries (roundfish, flatfish, Pandalus, and Nephrops). Demersal trawling is also used in the fisheries for Norway pout and sandeel which are landed for reduction purposes. Pelagic trawlers and purse seiners exploit herring, mackerel, horse mackerel, and sprat.

The roundfish, flatfish, and Nephrops stocks are mainly exploited by Danish and Swedish fleets consisting of bottom trawlers (Nephrops trawls with $>70 \mathrm{~mm}$ meshes and bottom trawls with $>90 \mathrm{~mm}$ mesh size), gillnetters, and Danish seiners. The number of vessels operating in Division IIIa has decreased in recent years. This is partly an effect of the EU withdrawal programme which until now has affected the Danish fleets only, but these fleets still dominate the fishery in Division IIIa. Pandalus is exploited by Danish, Swedish, and Norwegian shrimp trawlers.

The industrial fisheries are carried out by trawlers mainly of a size above 20 m using small-mesh trawl. The main target species are sandeel, Norway pout, sprat and blue whiting. By-catches in these fisheries have decreased since 1996, mainly due to the enforcement of by-catch regulations. Landings in the industrial fisheries in Division IIIa are given in Table 3.4.1.1.

There are important technical interactions between the fleets.

Misreporting and non-reporting of catches have occurred mainly in the cod fisheries. The amount is, however, not known. There are no discard data available for assessments. The time-series of age samples from landings for industrial purposes is short.

## Overview of resources

The Skagerrak-Kattegat area is to a large extent a transition area between the North Sea and the Baltic both in terms of hydrography and topography and the identity of stocks. The exchange of water between the North Sea and the Baltic is the main hydrographic feature of the area.

When assessed as separate stocks, several of the stocks in the Skagerrak show close affinities to the North Sea
stocks, in terms of both population dynamics (similar trends in recruitment and SSB) and biological indicators such as parasites or genetics. Tagging experiments have demonstrated extensive migration between the two areas for several species. Species with no clear stock boundary between the North Sea and Skagerrak include saithe, hake, cod (except for coastal populations in fjords), haddock, whiting, and Norway pout. Sandeel in the North Sea and Skagerrak is probably a complex of several local populations rather than separate populations in the two areas. The landings of sandeel from the Skagerrak area have had a composition of sandeel species different from that in the North Sea.

The main herring stocks exploited in the area are the North Sea autumn spawners and the stock of spring spawners spawning in the western Baltic and the southern part of Division IIIa. Both stocks have important components migrating into Division IIIa at some time during their life cycle. The juvenile herring in Division IIIa are mainly of North Sea stock origin, while the mature fish are predominantly spring spawners. The major part of the Western Baltic spring spawners migrates into Division IIIa outside the spawning season and is found in the Skagerrak in summer.

Cod in the Kattegat and Belt area are also associated with the western Baltic stock. The structure and extent of migrations is, however, not clear.

Most of the species are now assessed in conjunction with the stocks in the neighbouring areas - cod in the Skagerrak, haddock, saithe, Norway pout, and autumnspawning herring are assessed as part of the North Sea stocks, spring-spawning herring as part of the western Baltic stock. The state of these stocks is considered in the sections concerning the North Sea and the Baltic, respectively.

The cod in Skagerrak is assessed together with cod in the North Sea and the Eastern Channel. The stock is outside safe biological limits (see Section 3.5.2). The landings of cod in the Skagerrak in 2001 were 7100 t in the human consumption fishery. No by-catch was observed in the small-meshed industrial fisheries. Denmark and Sweden took the majority of catches.

The cod in Kattegat is outside safe biological limits. Landings in 2001 were 3900 t , which is the lowest in the time-series.

Haddock in Division IIIa is assessed together with haddock in the North Sea. The stock is harvested outside safe biological limits. The landings of haddock in Division IIIa in the human consumption fisheries
amounted to 1900 t in 2001. By-catches in the industrial fisheries were estimated at 200 t . Most of the catches are taken in the Skagerrak.

Assessment of the state of the whiting in Division IIIa was not possible. The landings of whiting in Division IIIa in 2001 are not yet available but are likely to be amongst the lowest observed. The major part was taken in the industrial fisheries. Most of the landings are taken in the Skagerrak.

The plaice in Division IIIa is harvested outside biological limits, as fishing mortality is higher than $\mathbf{F}_{\mathrm{pa}}$. Landings amount to 11700 t in 2001. About $75 \%$ of the landings were taken in the Skagerrak.

Sole in Division IIIa is harvested outside safe biological limits. Landings in 2001 were 560 t , substantially lower than the 1300 t in 1995.

The industrial fisheries yielded a total catch of 83000 t in 2001, well below the mean catches of 117000 t (19892001). Most of the catches consisted of sandeel, sprat, and herring with smaller catches of Norway pout and blue whiting (Table 3.4.1.1). By-catches of cod, haddock, and whiting in the industrial fisheries were all much reduced from 1996.

The landings of Nephrops and Pandalus in 2001 from Division IIIa amounted to 4000 t and 6400 t , respectively. The stocks seem to be able to sustain the present fishing mortality.

${ }^{4}$ 1999-2001 data provided from Denmark and Sweden. Other years, only data from Denmark is presented.

### 3.4.2

State of the stock/exploitation: The stock is outside safe biological limits. The present fishing mortality is above $\mathbf{F}_{\mathrm{pa}}$ and even above $\mathbf{F}_{\text {lim }}$. The estimated SSB of 5 400 t in 2002 is below $\mathbf{B}_{\text {lim }}$.

The spawning stock declined steadily from about 35000 t in the early 1970 s to about 10000 t in the 1990s, with a concurrent drop in recruitment from 2030 millions in the 1970s to around 10 millions in the 1990s. The fishing mortality exceeded 1.0 during most of the 1980s and 1990s. In the present state the fishery is dependent on the strength of incoming year classes. The present assessment indicates that recruitment has been well below average for the five last year classes (1997 to 2001).

Management objectives: There is no long-term management plan for this stock. The European Commission has proposed a recovery plan for the

Northern hake stock and the cod stocks in the Kattegat, the Skagerrak, the North Sea and the Eastern Channel, to the west of Scotland, and in the Irish Sea. The objective is to rebuild the stocks to levels greater than $\mathbf{B}_{\mathrm{pa}}$. The proposal includes a procedure for setting annual TACs and a system for limiting fishing effort in all fisheries catching cod. It is proposed that each year the TAC be set at a level that will result in an increase in biomass by $30 \%$ in the case of cod and $15 \%$ in the case of hake. The effort limitation system is based on the idea of reducing fishing effort in relation to the reduction in fishing mortality required to achieve the TACs. It is unclear if and when the proposal will be adopted and implemented.

ICES considers this recovery plan appropriate if it also includes a reduction of cod by-catches in other fisheries.

Precautionary Approach reference points (unchanged since 1999):

| ICES considers that: | ICES proposes that: |
| :--- | :--- |
| $\mathbf{B}_{\text {lim }}$ is 6400 t | $\mathbf{B}_{\mathrm{pa}}$ be set at 10500 t |
| $\mathbf{F}_{\mathrm{lim}}$ is 1.0 | $\mathbf{F}_{\mathrm{pa}}$ be set at 0.6 |

Technical basis:

| $\mathbf{B}_{\text {lim }}$ : lowest observed SSB | $\mathbf{B}_{\mathrm{pa}}: \mathbf{B}_{\text {lim }} * \exp (1.645 * 0.3)$ |
| :--- | :--- |
| $\mathbf{F}_{\text {lim }}:$ The spawning stock has declined steadily since the <br> early <br> 1970s at fishing mortality rates averaging $\mathrm{F}=1.0$. | $\mathbf{F}_{\mathrm{pa}}: \mathbf{F}_{\text {lim }} * \exp (-1.645 * 0.3)$ |
| $\mathbf{F}_{\text {lim }}$ is tentatively set equal to $\mathrm{F}=1.0$. |  |

Advice on management: ICES advises that there should be no fishing on this stock in 2003 unless an effective rebuilding plan is implemented, which aims at rebuilding the SSB to above $B_{p a}$. The proposed EC recovery plan is expected to be effective if the fishing industry complies with the provisions in this plan.

Rebuilding plan: The fishery should not be re-opened until a rebuilding plan is established. Because a large part of cod is taken as by-catch in fisheries for flatfish and Nephrops, the necessary reduction in fishing mortality on cod cannot be achieved by a reduction in TAC alone.

By-catches in the fisheries directed at Nephrops and flatfish could be reduced by measures, which improve species selectivity, e.g., escape windows or grids.

Relevant factors to be considered in management: The economically most important species in the Kattegat are cod, Nephrops, and sole, which each account for about $25 \%$ of the value of the total annual landings. By-catches of cod occur in the mixed sole and Nephrops fisheries. Management measures in the Kattegat need to take account of technical interactions
in the area. From 1997 to 2001 by-catches in the Nephrops fishery on average accounted for $12 \%$ of the cod catch in the Kattegat.

## Catch forecast for 2003:

Basis: (TAC constraint) Landings (2002) $=2800$, $\mathrm{F}(2002)=0.55 \mathrm{~F}_{\mathrm{sq}}=0.64, \mathrm{SSB}(2003)=6313$.

| $\mathrm{F}(2003)$ | Basis | Landings <br> $(2003)$ | SSB <br> $(2004)$ |
| :--- | :---: | :---: | :---: |
| 0 | 0 | 0 | 12132 |
| 0.23 | $0.2 \mathbf{F}_{\mathrm{sq}}$ | 1432 | 10146 |
| 0.35 | $0.3 \mathbf{F}_{\mathrm{sq}}$ | 2045 | 9305 |
| 0.46 | $0.4 \mathbf{F}_{\mathrm{sq}}$ | 2600 | 8550 |
| 0.52 | $30 \%$ SSB <br> increase | 2856 | 8203 |
| 0.6 | $\mathbf{F}_{\mathrm{pa}}=0.52 \mathbf{~ F}_{\mathrm{sq}}$ | 3205 | 7733 |
| 0.69 | $0.6 \mathbf{F}_{\mathrm{sq}}$ | 3556 | 7264 |
| 0.92 | $0.8 \mathbf{F}_{\mathrm{sq}}$ | 4345 | 6223 |
| 1.15 | $\mathbf{F}_{\mathrm{sq}}$ | 5000 | 5377 |

Weights in t .
Shaded scenarios considered inconsistent with the precautionary approach.

Medium- and long-term projections: Medium-term projections were carried out. Recruitment is generated from a Ricker stock-recruitment model.

The medium-term projections suggest that fishing at $\mathbf{F}_{\mathrm{pa}}$ leads to a more than $75 \%$ probability of the stock exceeding $\mathbf{B}_{\text {lim }}$ in 2004, and exceeding $\mathbf{B}_{\mathrm{pa}}$ in 2009.

Comparison with previous assessment and advice: The present assessment estimates last years SSB to be $2 \%$ lower than last year's assessment. The present advice is similar to last year's advice.

Elaboration and special comment: Landings have decreased from 15000 t in the 1970s to about 7000 t in the 1990s and less than 5000 t in the beginning of the 2000s. During the years 1991-1994 an unknown, but probably substantial amount has been either unreported or allocated to other areas. The quality of catch data from 1994 onward has improved, leading to improved reliability of the assessment.

The stock-recruitment plot indicates that strong recruitment requires a large spawning biomass, which will not occur at the present exploitation rates, particularly on younger ages (1-3). There is evidence that the stock interacts with neighbouring cod stocks in the Skagerrak and the Baltic Sea by way of migrations. These interactions add uncertainty to the assessment.

Source of information: Report of the Baltic Fisheries Assessment Working Group, 15-24 April 2002 (ICES CM 2002/ACFM:17).

Yield and spawning biomass per Recruit F-reference points:

|  | Fish Mort <br> Ages 3-5 | Yield/R | SSB/R |
| :--- | :---: | :---: | :---: |
| Average Current | 1.149 | 0.625 | 0.754 |
| $\mathbf{F}_{\text {max }}$ | 0.213 | 1.017 | 4.955 |
| $\mathbf{F}_{0.1}$ | 0.132 | 0.957 | 7.226 |
| $\mathbf{F}_{\text {med }}$ | 0.759 | 0.726 | 1.224 |

### 3.4.3 Whiting in Division IIIa (Skagerrak - Kattegat)

State of stock/exploitation: Based on the available information it was not possible to assess the state of the stock or identify safe biological limits. It is likely that this stock is linked to the North Sea stock for which the assessment is very uncertain, but which is likely to be outside safe biological limits.

Management objectives: There are no specific management objectives for this stock.

Advice on management: ICES recommends that the landings in 2003 be less than 1500 t as a precautionary value to restrict the potential for reexpansion of the fishery and misreporting from other regions.

Elaboration and special comment: The major part of the catch is taken as a by-catch in small-mesh fisheries. Total landings in 2001 are not available yet, but are likely to be amongst the lowest observed. The landings value advised for 2003 is consistent with ICES advice provided in 2001, and is based on the average of the catch during 1996-1998.

Source of information: Report of the Working Group on the Assessment of Demersal Stocks in the North Sea and Skagerrak, 11 - 20 June 2002 (ICES CM 2003/ACFM: 02 ).

*Preliminary: Norway 1997-1999.

### 3.4.4 Plaice in Division IIIa (Skagerrak - Kattegat)

State of stock/exploitation: The stock is harvested outside safe biological limits. The estimated SSB in 2002 is well above $\mathbf{B}_{\mathrm{pa}}$, but fishing mortality is above $\mathbf{F}_{\mathrm{pa}}$. Recruitment of year classes 1998 and 1999 are the highest in the time-series and this has resulted in a high estimate of recent SSB.

Management objectives: No explicit management objectives are set for this stock.

Precautionary Approach reference points (unchanged since 1999):

| ICES considers that: | ICES proposes that: |
| :--- | :--- |
| $\mathbf{B}_{\text {lim }}$ cannot be accurately defined. | $\mathbf{B}_{\mathrm{pa}}=24000 \mathrm{t}$. |
| $\mathbf{F}_{\text {lim }}$ cannot be accurately defined. | $\mathbf{F}_{\mathrm{pa}}=0.73$. |

Technical basis:

|  | $\mathbf{B}_{\mathrm{pa}}=$ smoothed $\mathbf{B}_{\text {loss }}$ (no sign of impairment). |
| :--- | :--- |
|  | $\mathbf{F}_{\mathrm{pa}}=\mathbf{F}_{\text {med }}$. |

Advice on management: ICES recommends a reduction in fishing mortality to less than $\mathrm{F}_{\mathrm{pa}}(\mathbf{0 . 7 3})$, corresponding to landings in 2003 of less than 18400 t . This implies a reduction in fishing mortality of at least $\mathbf{1 5 \%}$. Management of fisheries taking plaice must respect the stringent restrictions on the catch and discard rates advised for cod, with effective monitoring of compliance with those restrictions.

Relevant factors to be considered in management: Plaice is taken both in a directed fishery and as an
important by-catch in a mixed cod-plaice fishery. The North Sea Cod stock area includes the Skagerrak (Division IIIaN). Also, the Kattegat cod is in a precarious state (Division IIIaS). The plaice fisheries take cod as bycatch. The by-catch and discard limits advised for cod and other management measures that may be implemented to promote the recovery of cod need to be respected in the prosecution of the mixed plaice-cod fisheries. By-catch or discards should be quantified.

There is no long-term gain in yield for fishing mortalities above 0.22 .

## Catch forecast for 2003:

Basis: $\mathbf{F}_{\mathrm{sq}}=\mathrm{F}(99-01)$ scaled to $\mathrm{F}(01)=0.86$; Landings $(2002)=14.2 ; \operatorname{SSB}(2003)=73.4$.

| $\mathrm{F}(2003)$ | Basis | Landings (2003) | SSB (2004) |
| :--- | :--- | :--- | :--- |
| 0 | $0.0^{*} \mathbf{F}_{\mathrm{sq}}$ | 0.0 | 82.8 |
| 0.09 | $0.1^{*} \mathbf{F}_{\mathrm{sq}}$ | 2.7 | 80.0 |
| 0.17 | $0.2^{*} \mathbf{F}_{\mathrm{sq}}$ | 5.2 | 77.4 |
| 0.26 | $0.3^{*} \mathbf{F}_{\mathrm{sq}}$ | 7.6 | 74.9 |
| 0.34 | $0.4^{*} \mathbf{F}_{\mathrm{sq}}$ | 9.8 | 72.6 |
| 0.43 | $0.5^{*} \mathbf{F}_{\mathrm{sq}}$ | 70.4 |  |
| 0.52 | $0.6^{*} \mathbf{F}_{\mathrm{sq}}$ | 68.4 |  |
| 0.60 | $0.7^{*} \mathbf{F}_{\mathrm{sq}}$ | 11.9 | 66.4 |
| 0.69 | $0.8^{*} \mathbf{F}_{\mathrm{sq}}$ | 64.6 |  |
| 0.73 | $\mathbf{F}_{\mathrm{pa}}=0.85^{*} \mathbf{F}_{\mathrm{sq}}$ | 13.9 | 63.7 |
| 0.78 | $0.9^{*} \mathbf{F}_{\mathrm{sq}}$ | 62.9 |  |
| 0.86 | $\mathbf{F}_{\mathrm{sq}}$ | 17.5 | 61.3 |
| 0.95 | $1 . \mathbf{1}^{*} \mathbf{F}_{\mathrm{sq}}$ | 18.4 | 59.7 |
| 1.03 | $1.2^{*} \mathbf{F}_{\mathrm{sq}}$ | 19.2 | 58.3 |

Weights in ' 000 t .
Shaded scenarios considered inconsistent with the precautionary approach.

Medium- and long-term projections: No mediumterm projections have been carried out.

Comparison with previous assessment and advice:
The assessment undertaken this year has a very different
configuration compared to last year. Due to the addition of three new survey series and the inclusion of the 2001 data, SSB in 2001 is estimated to be $78 \%$ higher than last year and fishing mortality in 2000 is estimated $58 \%$ higher.

The advice for plaice in IIIa has been revised in May 2002 following a re-evaluation of the available data. The current advice is consistent with the advice provided in May 2002.

Elaboration and special comment: The estimates of fishing mortality and proposed $\mathbf{F}_{\mathrm{pa}}$ for plaice in Division IIIa are substantially higher than the corresponding estimates for plaice in the North Sea (Subarea IV). ACFM has previously speculated about the reasons for this difference, but there are no clear explanations. Reference points based on the estimated F will still be appropriate to use with this stock, but the values are not comparable to reference points for other plaice stocks.

The major plaice catches are taken in fisheries using Danish seine, trawl, and gillnet, targeting mixed species for human consumption including cod. The fishery is more directed at older fish than for most other plaice fisheries; however, due to the arrival of the strong 1998 and 1999 year classes, the catches of 2- and 3-year-old plaice was higher in 2001.

The analytical assessment uses information from three Danish commercial fleets and four survey series.

Multiannual TAC Arrangements and Recovery Plans: Section 3.5.17 reviewed a study on schemes for Multiannual advice on TACs for four plaice and two sole stocks. These studies indicated possible target fishing mortalities for specific TAC schemes. ICES considers that target values must be defined by management taking scientific studies into account. ICES has not received feed-back with specification of target reference points and therefore continues to provide advice based on the precautionary reference points consistent with previous practice.

| 1997 | 46387 | 26533 | 10291 | 1.2523 |
| 1998 | 44003 | 26021 | 8430 | 0.9207 |
| 1999 | 61863 | 27248 | 8740 | 1.5235 |
| 2000 | 133086 | 31899 | 8820 | 1.2960 |
| 2001 | 154847 | 55745 | 11560 | 0.8617 |
| 2002 | 46318 | 79256 |  | 0.8538 |
| Average | 56198 | 37398 | 12487 |  |

State of the stock/exploitation: The stock is harvested outside safe biological limits. Fishing mortality in 2001 was above $\mathbf{F}_{\mathrm{pa}}$ and landings decreased by $27 \%$ in 2001 compared to 2000. Spawning biomass (1180 t) is estimated to be slightly above $\mathbf{B}_{\mathrm{pa}}$. The stock size was exceptionally high in the period 1992-1996 due to strong recruitment in the period 1989-1993.

Recruitment has mostly been well below average since 1994.

Management objectives: There are no explicit management objectives for this stock. However, for any management objective to meet the proposed precautionary criteria, F should be less than the proposed $\mathbf{F}_{\mathrm{pa}}$ and spawning stock biomass should be maintained above the proposed $\mathbf{B}_{\mathrm{pa}}$.

Precautionary Approach reference points (unchanged since 1999):

| ICES considers that: | ICES proposes that: |
| :--- | :--- |
| $\mathbf{B}_{\text {lim }}$ is 770 t | $\mathbf{B}_{\mathrm{pa}}$ be set at 1060 t |
| $\mathbf{F}_{\text {lim }}$ is 0.47 | $\mathbf{F}_{\mathrm{pa}}$ be set at 0.30 |

Technical basis:

| $\mathbf{B}_{\text {lim }}: \mathbf{B}_{\mathrm{pa}} * \exp (-1.645 * 0.2)$ | $\mathbf{B}_{\mathrm{pa}}:$ MBAL |
| :--- | :--- |
| $\mathbf{F}_{\text {lim }}: \mathbf{F}_{\mathrm{med}} 98$ excluding the abnormal years around 1990 | $\mathbf{F}_{\mathrm{pa}}:$ consistent with $\mathbf{F}_{\text {lim }}$ |

Advice on management: ICES recommends that current fishing mortality should be reduced to below $F_{p a}$ corresponding to landings in 2003 of less than 275 t.

Relevant factors to be considered in management: This stock supported catches at $250-450 \mathrm{t}$ for 35 years, prior to the occurrence of strong recruitments in the period of 1989 to 1993. These recruitments led to large increases in SSB and yield. Since 1994, recruitment has returned to the earlier low values.

Regardless of short-term management measures, biomass and yield will decline over the next few years under the lower recruitment regime. Recruitments appear to have periods of generally high or low year classes that are not closely tied to the size of the spawning biomass. This suggests that environmental factors might be important for recruitment and therefore contribute uncertainty to medium-term projections and biological reference points.

## Catch forecast for 2003:

Basis: $\mathrm{F}(2002)=\mathbf{F}_{\mathrm{sq}}=\mathrm{F}(2001)=0.46$; Landings (2002) $=$ 430; $\operatorname{SSB}(2003)=1092$.

| F (2003) | Basis | Landings <br> $(2003)$ | SSB <br> $(2004)$ |
| :---: | :---: | :---: | :---: |
| 0.09 | $0.2 \mathbf{F}_{\mathrm{sq}}$ | 92 | 1390 |
| 0.19 | $0.4 \mathbf{F}_{\mathrm{sq}}$ | 178 | 1298 |
| 0.28 | $0.6 \mathbf{F}_{\mathrm{sq}}$ | 257 | 1213 |
| 0.30 | $0.65 \mathbf{F}_{\mathrm{sq}}\left(=\mathbf{F}_{\mathrm{pa}}\right)$ | 275 | 1193 |
| 0.37 | $0.8 \mathbf{F}_{\mathrm{sq}}$ | 330 | 1135 |
| 0.46 | $\mathbf{F}_{\mathrm{sq}}$ | 397 | 1062 |

Weights in t .
Shaded scenarios considered inconsistent with the precautionary approach.

Comparison with previous assessment and advice: The present assessment indicates a lower SSB in 2001 ( $37 \%$ ) and higher fishing mortality ( $48 \%$ ) for year 2000 than last year's assessment. Part of this change is due to data problems connected to a recent change in spatial distribution of catches. This has led to problems in sampling coverage. There has been a tendency of the assessment in recent years to over-estimate SSB and under-estimate $F$.

Elaboration and special comment: The analytical assessment is based on landings data and commercial CPUE series. The assessment is considered very uncertain. Maturity is not measured but assumed, no age readings are available from Skagerrak for 2001 and catchability has decreased for all age groups in the two commercial tuning series. Official catch statistics are considered unreliable for the early 1990s, but are thought to be fairly accurate since 1994.

Source of information: Report of the Baltic Fisheries Assessment Working Group, 15-24 April 2002 (ICES CM 2002/ACFM:17).

State of the stock/exploitation: The state of the stock is not known, relative to precautionary reference points. Stock size is estimated to have increased since the beginning of the 1990s and is above the long-term average since 1995. Fishing effort has declined since 1993 and is currently estimated to be at the lowest observed level. Predator abundance has declined over the last 3 years. Recruitment of the year class 2000 (in 2002) is above average.

Management objectives: There are no explicit management objectives for this stock.

Advice on management: ICES recommends that landings in 2003 should not exceed 14750 t, based on an estimated increase in stock size of around $20 \%$ from 2002 to 2003 and corresponding to the current level of exploitation.

Relevant factors to be considered in management: The perception of the state of the stock in 2002 is based on an assessment that takes predation into account. The assessment shows that predators remove annually about $60 \%$ of the stock biomass, while only about $10 \%$ is removed by fishing. The exploitable biomass comprises only few age groups (1-3) of which age group 2 and older constitute around $70 \%$ in weight of the total catch.

Sorting grids or other means of facilitating the escape of fish should be implemented in this fishery.

Catch forecast for 2003: Not available.

Comparison with previous assessment and advice: In previous years, analytical assessments (XSA) have been applied to assess this stock as a basis for catch forecasts. However, since the natural mortality of this species is most likely to be several times higher than the fishing mortality, cohort analysis methodology is not well suited for this species. The few age groups in the stock further add to uncertainty of the XSA estimates. ICES has investigated alternative assessment
models. A stock production model (SPP) taking predation into account has been introduced. For the beginning of the time-series, the SPP model estimates the stock level to be similar to that estimated by XSA, while for the most recent years (since $\approx 1994$ ) SPP estimates the stock to be at a higher level than estimated by XSA. This is in agreement with the survey results and the commercial LPUE data.

Elaboration and special comments: Pandalus borealis is fished by bottom trawls at $150-400 \mathrm{~m}$ depth throughout the year by Danish, Norwegian, and Swedish fleets.

Strong fluctuations in the Pandalus stocks are frequently observed. Predator pressure as well as the low number of age groups in the stock contributes significantly to such fluctuations. The natural mortality for Pandalus is likely to be substantially higher than the fishing mortality and fluctuates considerably according to the abundance of predators.

Because of the potentially large impact of predation on stock dynamics, the biological consequences of any specific fishing mortality rate can be highly variable. At low predator abundance, even a low fishing mortality (F) may be a high proportion of total mortality (Z), whereas at high predator abundance, a higher F may still be a small part of Z . It is not yet possible to identify appropriate precautionary fishing mortality reference points $\left(\mathbf{F}_{\text {lim }}, \mathbf{F}_{\mathrm{pa}}\right)$ for such circumstances, and reference points based on total mortality may be more sound biologically.

The assessment was based on commercial catches, survey indices of available biomass, recruitment, and amount of predators.

| 2002 | 2133 | 146800 |  | 8.2 |
| Average | 106441 | 13182 | 12.6 |  |

State of stock/exploitation: SSB has been relatively stable over the last five years, but the stock is being harvested outside of biological limits. Fishing mortality is 0.50 for adults and 0.25 for the juveniles ( 0 - and 1ringers), which is substantially greater than $\mathbf{F}_{\text {max }}$. The age structure in the catch appears to be relatively stable over the last four years.

Management objectives: There are no explicit management objectives for this stock.

Precautionary Approach reference points: Precautionary Approach reference points have not been defined. The continued development of an analytical assessment may allow definition of PA reference points in the near future. Based on a comparison to other herring stocks all likely candidates of $\mathbf{F}_{\mathrm{pa}}$ will be less than $\mathbf{F}_{\text {max }}$.

Advice on management: ICES recommends that the fishing mortality be reduced to less than $F_{\text {max }}$, corresponding to catches in 2003 of less than 84000 $t$. According to the recent geographic distribution of catches, approximately half of the total catch should be taken from the Subdivisions 22-24.

Relevant factors to be considered in management: Section (3.5.8) on North Sea herring (autumn spawners) states: "The fisheries on herring in Division IIIa should be managed in accordance with the management advice given on spring spawning herring", and the North Sea stock is now above $\mathbf{B}_{\mathrm{pa}}$. A considerable part of the landings of juvenile herring in Division IIIa originates from the North Sea stock. An abundant 2000 year class of North Sea autumn spawner herring is expected to be present in the area as one-winter-ringers in 2002. The 2001 North Sea autumn spawner year class also appears to be abundant and this year-class will be present in Div. IIIa as 0 -ringers in 2002. Recently, this fishery has been managed in a manner consistent with the management of the herring in the North Sea. As the North Sea stock recovers, the need for a separate management of Subdivisions 22-24 + Division IIIa herring stock increases.

In the Baltic the TACs for herring apply to several herring stocks, including the component of this stock in Subdivisions $22-24$, and there is no specific instrument that allows control over the exploitation of springspawning herring in Division IIIa and Subdivisions 2224. The herring TAC for the Baltic should be split and individual TACs applied to the stocks, i.e. Subdivisions $22-24$, Subdivisions $25-29+32$ (excluding Gulf of Riga herring), Gulf of Riga herring, Subdivision 30 and Subdivision 31.

Catch forecast for 2003: Basis: $\mathrm{F}(2002)=\mathbf{F}_{\mathrm{sq}}=$
$\mathrm{F}(1999-2001)=0.498 ; \quad$ Landings $\quad(2002)=107$;
$\operatorname{SSB}(2002)=140$.

| $\mathrm{F}(2003$ <br> onwards) | Basis | SSB <br> $(2003)$ | Landings <br> $(2003)$ | SSB <br> $(2004)$ |
| :---: | :---: | :---: | :---: | :---: |
| 0 | $0 \mathbf{F}_{\mathrm{sq}}$ | 141 | 0 | 224 |
| 0.202 | $\mathbf{F}_{0.1}$ | 139 | 48 | 183 |

| 0.547 | $1.1 \mathbf{F}_{\mathrm{sq}}$ | 133 | 116 | 129 |

Weights in ' 000 t .
Shaded scenarios considered inconsistent with the precautionary approach.

Comparison with previous assessment and advice: The assessment carried out in 2002 is the first accepted analytical assessment. The results are very similar to a provisional assessment provided last year.

Elaboration and special comments: Herring of this stock are taken in the Northeastern part of the North Sea, Division IIIa, and Subdivisions 22-24. Division IIIa has directed fisheries by trawlers and purse seiners (fleet C), while Subdivisions 22-24 have directed trawl, gillnet, and trapnet fisheries (fleet F). The herring bycatches taken in Division IIIa in the small mesh trawl fishery for Norway pout, sandeel, and sprat (fleet D) are mainly autumn spawners from the North Sea stock. After a period of high landings in the early 1980s the combined landings of all fleets have decreased to below the long-term average.

The TACs in Division IIIa in 2001 were: 1) for the directed fishery 80000 t , and 2) for by-catch in the small mesh fisheries 21000 t . The TAC comprises both the autumn- and spring-spawning stocks in the area. The spring spawners are also fished in the Baltic, under the overall IBSFC herring TAC of 300000 t (Subdivisions $22-32$ ). The TACs in Div. IIIa for 2002 are 80000 t for directed fishery and a total of 21000 t for by-catches in the small mesh fisheries.

The otolith microstructure method to calculate the proportion of spring and autumn spawners caught in these areas has been implemented, all catch and IBTS data for the period 1991-1999 has been revised. Continued development of the stock identification methods should be applied to explore the importance of local stock components in the area.

Analytical assessment is based on catch data and acoustic and trawl survey results. In order to continue to improve the assessment, a comprehensive survey covering the whole stock is needed.

### 3.4.8 Sprat in Division IIIa

State of stock/exploitation: The state of the stock is unknown. Sprat in this area is short-lived with large annual natural fluctuations in stock biomass.

Management objectives: There are no explicit management objectives for this stock.

Advice on management: As sprat is mainly fished together with juvenile herring the exploitation of sprat will be limited by the restrictions imposed on fisheries for juvenile herring. With the current management regime, where there are by-catch ceilings of herring as well as by-catch percentage limits, the sprat fishery is controlled by these factors.

Relevant factors to be considered in management: Sprat cannot be fished without significant by-catches of herring except in years with high sprat abundance. The most recent period when this occurred was 1994-1995. The available surveys are not reliable indicators of sprat abundance in Division IIIa. Therefore, fishing possibilities in 2002 cannot be projected.

Management of this stock should consider management advice given in Section 3.5.8 (Herring in Subarea IV, Division VIId, and Division IIIa).

Elaboration and special comment: The directed sprat fishery serves a very small market. Most sprat catches are taken in an industrial fishery where catches are limited by herring by-catch restrictions. This combination of factors has prevented full utilisation of the occasional strong year class. Such year classes emerge and disappear very quickly.

Landings of sprat in Division IIIa averaged about 70000 t in the 1970 s , but since 1982 have typically been around 20000 t , except in 1994-1995.

Source of information: Report of the Herring Assessment Working Group for the Area South of $62^{\circ} \mathrm{N}$, March 2002 (ICES CM 2002/ACFM:12).

### 3.4.9 Sandeel in Division IIIa (Skagerrak - Kattegat)

State of stock/exploitation: Based on the available information it was not possible to assess the state of the stock or identify safe biological limits.

Management objectives: There are no explicit management objectives for this stock.

Elaboration and special comment: ICES notes that this is an unregulated fishery on an important prey species.

The fishery is an extension of the North Sea fishery into Division IIIa, but with smaller vessels working closer inshore, mostly along the coast of Jutland.

The catches in 2001 were 25500 t , which is an increase compared to the values in 1998-2000, but still below the average of 32000 t for the period 1989-2001.

The available information suggests that Subarea IV and Division IIIa can be combined to one stock unit. No assessments of sandeel in Division IIIa have been carried out so far. Biological data for this area are sparse and would have to be evaluated before a decision is made about treating sandeels in Subarea IV and Division IIIa as one stock.

Source of information: Report of the Working Group on the Assessment of Demersal Stocks in the North Sea and

Skagerrak, 11 - 20 June 2002 (ICES CM 2003/ACFM: 02 ).

## Sandeel in Division IIIa (Skagerrak - Kattegat)

### 3.4.10

## Anglerfish in Division IIIa (Skagerrak and Kattegat)

Anglerfish in this area is assessed as part of the complex covering Division IIIa (Skagerrak and Kattegat), Sub-area IV (North Sea) and Division VIa (West of Scotland), see section 3.7.7.
that the results reported in "Analysis of possibilities of limiting the annual fluctuations in TACs" (Reference FISH-2000-02-01) should be interpreted with care and conclusions should be based on comparative patterns rather than on absolute estimates of probability or risk.

## 2) Targets and limits

The basic management scenarios that were investigated consisted of a target F and a constraint on the annual percentage changes in TAC, which would be permitted. The results from these scenarios were presented in terms of mean yield and the risk of the SSB being below $\mathbf{B}_{\mathrm{pa}}$.

In general, ACFM observed a non-linear relationship between risk of SSB being reduced to less than $\mathbf{B}_{\mathrm{pa}}$ and the magnitude of TAC constraints. In most short- and medium-term simulations, a TAC constraint of $10 \%$ (i.e., restricting annual changes in TAC to $10 \%$ or less) had substantially greater risk than a $20 \%$ constraint, but the difference in risk of from $20 \%$ to $40 \%$ constraints was much less. It was also clear that the current state of the stock also had an important effect on the results. For stocks below $\mathbf{B}_{\mathrm{p}}$, imposing a restrictive constraint on the TAC delayed recovery and thus led to an increased risk to the stock. Conversely, for stocks above $\mathbf{B}_{\mathrm{pa}}$, such a TAC constraint served to reduce the risk to the stock. For several stocks, the projections indicated a clear optimum target F for minimising risk and maximizing yield in the medium or long term.

Results from the individual stocks are summarized below, together with the current perception of the state of each stock.

> Plaice in the Skagerrak ( $2001 \mathrm{SSB}=\mathbf{1 3 0} \% \mathrm{~B}_{\mathrm{pa}}, 2001$ $\mathrm{~F}=112 \% \mathrm{~F}_{\mathrm{pa}}, \mathrm{F}_{\mathrm{pa}}=\mathbf{0 . 7 3}$ ):

A $10 \%$ TAC constraint has substantially greater risk than looser constraints, and risk is similar at various levels of F. For example, in the short-term, a target F of 0.4 with a $20 \%$ TAC constraint produces approximately one-third of the risk produced with a $10 \%$ TAC constraint and also produces some gains in yield. Although simulation results are sensitive to the assumed stock-recruit model, this pattern is similar for all assumed models. In the medium term, a $10 \%$ constraint also produces greater risk, and F has slightly more effect on risk, but only affects yield at very low Fs. In the long-term, the TAC constraint has less effect, and risk is much more a function of F , because the stock is fluctuating less and is nearly in equilibrium. The target $F$ that produced the greatest yield and least risk in the long term was 0.275 . In conclusion, the $10 \%$ TAC constraint appears to be too restrictive, because it does not allow a quick response to strong recruitment or poor conditions. Furthermore, target F should be less than $\mathrm{F}_{\mathrm{pa}}$.

Plaice in the North Sea ( 2001 SSB= $96 \%$ B $_{\text {pa }} 2001$ $\mathrm{F}=143 \% \mathrm{~F}_{\mathrm{pa}}, \mathrm{F}_{\mathrm{pa}}=\mathbf{0 . 3 0}$ ):

In the short-term, risk is more affected by the target F than the level of TAC constraint, because simulations are starting with SSB levels that are less than $\mathbf{B}_{\mathrm{pa}}$. Alternative stock-recruit models produced similar results. In the medium-term, yield is similar among all scenarios, but risk is greatly increased at greater target Fs. In the long term, target Fs greater than 0.35 produce less yield and great risk, with TAC constraints also producing less yield. There was no clear optimum target F for minimizing risk and maximizing yield in the long term. In conclusion, there is substantial risk of SSB being below $\mathbf{B}_{\mathrm{pa}}$ in the short, medium and long term when the target is $\mathbf{F}_{\mathrm{p}}$, regardless of TAC constraints.

Plaice in the Irish Sea ( $2001 \mathrm{SSB}=179 \% \mathrm{~B}_{\mathrm{pa}} 2001$
$\left.\mathrm{~F}=69 \% \mathrm{~F}_{\mathrm{pa}}, \mathrm{F}_{\mathrm{pa}}=\mathbf{0 . 4 5}\right)$ :

In the short term, the more restrictive TAC constraints have less risk than looser constraints, because simulations are starting with SSB levels that are much greater than $\mathbf{B}_{\mathrm{pa}}$ and low Fs, and constraints do not allow F to quickly increase to the target. Risk is lower at low target Fs, but there is substantial loss in yield. A target F of 0.363 produces much less risk than $\mathbf{F}_{\mathrm{pa}}$ with no loss of yield for much reduced risk. Yield is much less at target Fs of less than 0.275. In the long-term the $10 \%$ TAC constraint produced relatively high risk and low yield. There is substantial risk of equilibrium SSB produced by a target of $\mathbf{F}_{\mathrm{pa}}$ being less than $\mathbf{B}_{\mathrm{pa}}$. The target F that produced the greatest yield and least risk in the long term was 0.275 . In conclusion, the $10 \%$ TAC constraint appears to be too restrictive. Furthermore, target F should be less than $\mathbf{F}_{\mathrm{pa}}$.

## Plaice in the Eastern English Channel (2001

 $\mathrm{SSB}=119 \% \mathrm{~B}_{\mathrm{pa}} 2001 \mathrm{~F}=\mathbf{1 1 6} \%_{\mathrm{pa}}, \mathrm{F}_{\mathrm{pa}}=\mathbf{0 . 4 5}$ ):In the short term, the more restrictive TAC constraints have less risk than no constraints, because simulations are starting with SSB levels that are much greater than $\mathbf{B}_{\mathrm{pa}}$. In the medium term, $\mathbf{F}_{\mathrm{pa}}$ produces the most yield at low risk. In the long term target Fs greater than $\mathbf{F}_{\mathrm{pa}}$ produce much less yield and have much greater risk. The $10 \%$ TAC constraint substantially increases risk, particularly at higher target Fs. Simulations at lower Fs produce SSBs that are much greater than the observed maximum. In conclusion, the $10 \% \mathrm{TAC}$ constraint appears to be too restrictive, but $\mathbf{F}_{\mathrm{pa}}$ appears to produce low risk and high yield.

Sole in the North Sea ( 2001 SSB=113\%B ba $_{\text {pa }} 2001$ $\mathrm{F}=\mathbf{1 1 5 \%} \mathrm{F}_{\mathrm{pa}}, \mathrm{F}_{\mathrm{pa}}=\mathbf{0 . 4 0}$ ):

In the short term, target $F$ and to a lesser extent TAC constraints affect on risk. Target Fs greater than 0.5 produce a very high risk, with or without TAC constraints. At lower target Fs, TAC constraints have more affect on risk. The $10 \%$ TAC constraint produces substantially greater risk than looser constraints, irrespective of target Fs, probably resulting from highly variable recruitment. The $10 \%$ TAC constraint is also much riskier in the medium term. In the long term, risk is more a function of $\operatorname{target} \mathrm{F}$, with losses in yield at Fs greater than 0.4 . There was no clear optimum target F for minimizing risk and maximizing yield in the long term. In conclusion, the $10 \%$ TAC constraint appears to be too risky, but a $20 \%$ TAC constraint with a target F of $\mathbf{F}_{\mathrm{pa}}$ or less has substantially less risk.

Sole in the Eastern English Channel (2001 $\mathrm{SSB}=\mathbf{1 5 8} \% \mathrm{~B}_{\mathrm{pa}} 2001 \mathrm{~F}=\mathbf{8 5} \% \mathrm{~F}_{\mathrm{pa}}, \mathrm{F}_{\mathrm{pa}}=\mathbf{0 . 4 0}$ ):

In the short term, there is a distinct tradeoff between risk and yield in which target Fs greater than $\mathbf{F}_{\mathrm{pa}}$ have substantially greater risk, but also produce greater yield.

The $10 \%$ TAC constraint also has greater risk for the lower target Fs. The target F that produced the greatest yield and least risk in the medium term was 0.3 , but the $10 \%$ TAC constraint had greater risk at all target Fs. The target F that produced the greatest yield and least risk in the long term was $0.2-0.3$, and the $10 \%$ TAC constraint was more risky. In conclusion, the $10 \%$ TAC constraint appears to be too risky, but a $20 \%$ constraint with a target $F$ of between 0.2 and 0.3 has relatively low risk and produces relatively high yields.

## 3) Recovery Plans

This request could not be completely addressed with the information that was provided, because the proposed rebuilding strategies were not directly simulated. Although ACFM cannot respond to the specific request, the general simulation results show that TAC constraints should be not be applied during rebuilding and TACs should be as responsive as possible to the perceived stock conditions. One technical aspect of a rapid response is that some assessment methods that assume stable F may not perform well for monitoring rebuilding.

### 3.4.11 Response to the request from DG Fish concerning TACs for 2002 for certain species Plaice in Division IIIa (Skagerrak and Kattegat)

The EC has requested ICES to reconsider its TAC advice for plaice in Division IIIa (Skagerrak and Kattegat) for 2002 taking into account any additional data that may have become available since the assessment was done in 2001.

ICES advised based on its assessment in June 2001 as follows:

## Advice on management: ICES recommends that

 fishing mortality should be less than the proposed $\mathrm{F}_{\mathrm{pa}}$ (0.73), corresponding to landings in 2002 of less than 8500 t.ICES also commented that the assessment was uncertain.

The present document provides an update of the advice for 2002 based on new information now available for 2001. The analysis presented in two background papers is based on incomplete and preliminary data for 2001. These two papers are attached.

## ICES Comments

1. The plaice in Division IIIa (Skagerrak and Kattegat) is assessed by the ICES Working Group on the Assessment of Demersal Stocks in the North Sea and Skagerrak (WGNSSK). This group will meet again in late June 2002 and at that time will have the complete data 2001 set available. Also the Argos 2002 survey data will be available at that time. The assessment made by WGNSSK will be reviewed by the ICES Advisory Committee on Fishery Management (ACFM) in October 2002. Also, ACFM will at that time formulate ICES advice for 2003.
2. The fishery on plaice in Division IIIa is almost entirely Danish and the Danish Institute of Fisheries Research (DIFRES) provides almost all data for the assessment (tuning series and age-length keys). Therefore, ICES asked DIFRES to conduct a study to allow ICES to respond to this request. This study was supplemented by data analysis made by the ICES Secretariat.
3. The provisional total catch is $11,800 \mathrm{t}$. The expected catch for 2001 under the assumption of unchanged fishing mortality was 8,600 tonnes.
4. The 2001 catch at age distribution differs considerably from the age distribution predicted at the most recent assessment. It contains considerably more age 2 and 3 plaice (year-classes 1999 and 1998) and less of age 6 and older. In the provisional catch fish of age 4 or less account for $57 \%$ of the
fish, whereas they were predicted to account for 36\%.
5. For 2001 the predicted and preliminary data on mean weight-at-age are almost identical.
6. Compared to 2000, the effort has increased by 2,12 and $10 \%$ for trawlers, gill-netters and Danish seiners, respectively, whereas catches have increased by 31,32 and $26 \%$. The preliminary CPUE data, which are used as the stock abundance indicators, were 12,3 and $31 \%$, respectively, above the predicted values.
7. Data from three abundance surveys are available; IBTS conducted by the Swedish vessel Argos during the first quarter of each year, and Danish surveys conducted by the vessel Havfisken in the first and fourth quarter of each year.
8. Inter-sessional work after June 2001has been conducted on the two R/V Havfisken survey data and the time series have been both revised and extended. The new indices available thus cover the period 1996-2001 for the spring survey, and 19942001 for the fall survey (Figure 4). They indicate that all year classes from 1997 and later are above average and that the year classes 1998 and 1999 are large. The Argos survey series including data for spring 2002 similarly show a high level of recruitment in recent years.
9. The re-evaluation is done as follows

- The assessment model (WGNSSK 2001) uses age groups 2-11+. This re-evaluation uses age group 2$6+$. This is done to avoid influence of small contributions of old fish
- the age composition of N6+ is taken as estimated by the 2001 assessment
- fishing mortality for 2001 for ages 2 and 3 should resemble $\mathbf{F}_{\text {sq. }}$. This is done to mimic the shrinkage used in the June 2001 assessment.

This is not a full assessment but an $a d-h o c$ solution for an evaluation of the preliminary data.

The estimated parameters are

- Fishing mortality for ages $2,3,4,5$ and $6+$ and
- Stock size as of $1^{\text {st }}$ January 2001 for ages 2,3,4 and 5.

10. The estimated stock size as of $1^{\text {st }}$ January 2001 is compared with the estimate adopted in the June 2001 assessment

11. The estimated fishing mortality is compared with the expected fishing mortality for 2001 on the graph below

12. The catch option table is then revised to be:

Landings 2001 $=12,300 \mathrm{t}, \operatorname{SSB}(2002)=57,100 \mathrm{t}$, $\mathrm{F}_{2001}(4-8)=0.51$.

| $\mathrm{F}_{2002} / \mathbf{F}_{\mathrm{sq}}$ | $\mathrm{F}_{2002}(4-8)$ | Yield (2002) | $\mathrm{SSB}(2003)$ |
| :---: | :---: | :---: | :---: |
| 0 | 0 | No Fishing | 59,991 |
| 0.4 | 0.31 | 5,657 | 56,411 |
| 0.6 | 0.47 | 8,046 | 54,764 |
| 0.8 | 0.62 | 10,202 | 53,203 |
| 0.9 | 0.70 | 11,203 | 52,453 |
| 0.94 | 0.73 | 11,590 | 52,159 |
| 1 | 0.78 | 12,158 | 51,723 |
| 1.1 | 0.85 | 13,070 | 51,011 |
| 1.2 | 0.93 | 13,943 | 50,317 |
| 1.3 | 1.01 | 14,779 | 49,640 |

13. The adopted precautionary reference points $\left(\mathbf{B}_{\mathrm{pa}}=\right.$ $24,000 \mathrm{t}$ and $\mathbf{F}_{\mathrm{pa}}=0.73$ ) are based on an exploitation pattern that resembles that existing in the 1998-2000 period. This exploitation pattern indicates a substantially higher average age in the catches than what was observed in the preliminary catch compositions for 2001. Should such an exploitation pattern prevail in the fishery then the $\mathbf{F}_{\mathrm{pa}}$ reference
point would no longer be valid and a lower reference fishing mortality is implied.
14. The 2002 TAC was set taking cod by-catches into consideration. There are no available data on cod bycatches for 2001. The cod-by-catch relates to effort rather than to catch of plaice and effort is related to fishing mortality. The fishing mortality for 2002 should be below the current level if total cod bycatch should be below the level seen in recent years. $\mathbf{F}_{\mathrm{pa}}$ is slightly below the average fishing mortality for 1998-2000, but above the (uncertain) 2001 estimate.
15. The re-evaluation is based on preliminary data and the uncertainty on the estimates is larger than in an assessment based on the full dataset. In addition, also due to uncertainty about the exploitation pattern the management option table is only indicative of the change in projections.
16. The 2001 information suggests a $32 \%$ higher status quo prediction for 2002 than presented in 2001, implying that the 2002 TAC could be increased by up to $32 \%$ without significant additional risk to the stock.

### 3.5 Stocks in the North Sea (Subarea IV)

### 3.5.1 Overview

## Description of the fisheries

The fisheries in the North Sea can be grouped into demersal and pelagic human consumption fisheries and into industrial fisheries, which land their catch for industrial purposes. Demersal human consumption fisheries usually target a mixture of roundfish species (cod, haddock, whiting), or a mixture of flatfish species (plaice and sole) with a by-catch of roundfish. A fishery directed at saithe exists along the shelf edge. The catch of these fisheries is landed for human consumption. The pelagic fisheries mainly target herring, mackerel, and horse mackerel. Although most of the landings of these species may be landed for human consumption purposes, part of the landings are used for fishmeal and fishoil. The catch of the industrial fisheries mainly consists of sandeel, Norway pout, and sprat. The industrial catches also contain by-catches of other species, including herring, haddock, and whiting (Table 3.5.1.1). In addition to the finfish fisheries, smaller fleets exist which fish for crustaceans, including Nephrops, Pandalus, and brown shrimp (Crangon crangon).

Each fishery uses a variety of gears. Demersal fisheries: otter trawls, pair trawls, twin trawls, seines, gillnets, beam trawls. Pelagic fisheries: pelagic trawls and purse seines. Industrial fisheries: small-meshed otter trawls, pelagic trawls, and purse seines.

Some major technological developments changed the fisheries in the North Sea during and after the 1960s such as the development of the beam trawl fishery for flatfish, purse seines in the pelagic fishery, and large pelagic trawls to replace driftnets. In recent years twin trawls have been introduced in the fishery for flatfish and roundfish. The introduction of power blocks in the 1960s has enormously increased the possibilities for the purse seiners. Right up to the present time further development of electronic equipment such as satellite navigation, fish finders, and sonar has increased the fishing efficiency of the fleets.

The trends in landings of the most important species landed by these fleets since 1970, together with the total international landings, are shown in Table 3.5.1.2 and in Figure 3.5.1.1. The demersal landings have steadily declined over the period. The pelagic landings, dominated by herring, decreased to a minimum in the late 1970s, when the fishery for herring was closed, but increased again up to over 1 million $t$ in the period 1987-1995. In 1996 they were reduced by about half and have remained stable since then. The landings in the industrial fisheries increased to approximately 1.8 million t in the mid-1970s, and have fluctuated between 1 and 1.5 million $t$ in recent years. These landings show the largest annual variations, due to the
short life span of the species. The total landings reached 3 million t in 1974, and have been around 2.5 million t since the 1980s.

Average landings by fleet segment in the North Sea demersal fisheries are shown in Table 3.5.1.3. The average landings allow a comparison to be made between different fleet segments. However, the interpretation possibilities of Table 3.5.1.3 are hindered by the fact that discards are not included in the table so that the actual catch of the different fleet segments cannot be evaluated.

Most commercial species are managed by TAC/quota regulations that apply to Subarea IV or a combination of Subarea IV with an adjacent area. The national management measures with regard to the implementation of the quota in the fisheries differ between species and countries. The industrial fisheries are subject to regulations for the by-catches of protected species.

## Data

The biological data available from scientific sources for the assessment of roundfish, flatfish, herring, and mackerel are relatively good. The level of biological sampling of most of the commercial landings has been maintained. Discard data are only used directly in assessments for haddock and whiting, but a historical series exists only for one country. Several countries now collect discard data on a recurrent basis, although many of these data have yet to be incorporated in the assessments.

Data on landings, fishing effort, and species composition are available from all industrial fisheries. There are catch and effort data available for many fisheries, but it is uncertain how reliably these data reflect trends in effective effort, i.e. nominal effort after corrections for technological improvements. Restrictive management measures (TAC's) have also resulted in changes in the fishing practice of some fleets and redirected their effort to other species. In a number of cases this has lead to abandoning the use of time-series of commercial CPUE data in the assessments (cod, haddock, whiting, plaice). In some recent years there was misreporting of roundfish landings associated with restrictive quotas. Substantial underreporting of cod landings occurred in 1998 and 2001.

Several series of research vessel survey indices are available for most species. Quarterly data were available from the International Bottom Trawl Survey for a period of 6 years (1991-1996) and these were used in the assessment of some stocks. This survey covers quarters 1 and 3 since then. For herring and mackerel the
spawning stock sizes are estimated by annual larvaeand acoustic surveys (herring) or intermittent egg surveys (mackerel).

Analytical assessments were performed on cod, haddock, whiting, saithe, herring, mackerel, plaice, sole, sandeel, and Norway pout.

Multispecies considerations are not incorporated in the assessments or the forecasts for the North Sea stocks. However, average natural mortalities estimated by multispecies assessments are incorporated in the assessments of cod, haddock, whiting, herring, sprat, sandeel, and Norway pout.

## Overview of resources

In the past 10 years the state of the stock for most roundfish and flatfish species in the North has further deteriorated. Some of these stocks have reached a historical low within this period. One of the major causes of this deterioration is the continuous very high level of exploitation. This exploitation has lead to a reduction in the number of age groups in the stocks and fishing opportunities have consequently become more dependent on the success of recruitment. Recruitment for most stocks is, however, very variable. For a number of species (cod, whiting, plaice) recruitment in most years has been lower than in previous decades. At the same time it is observed that a number of species (cod, haddock, whiting, sole, plaice) simultaneously show a reduction of growth. On the contrary, other (southern) species like sea bass and red mullet have increased and in some times attracted a fishery. There is considerable speculation on the reasons for the observed changes. The reduction in recruitment can be explained by a reduction in the production of eggs by the reduced spawning stocks, but it cannot be excluded that changes in the environment play a role. In the last 10 years the climate has changed not only on land but also in the sea, and mean temperatures in the sea have increased. Changes in the sea currents have also been observed. The changes in environmental conditions may be responsible as well for changes in the distribution and abundance of the different species.

In the North Sea all stocks of roundfish and flatfish species have been exposed to high levels of exploitation. The present assessments indicate that the fishing mortality in the last three years has been reduced for whiting and saithe, but not for cod and haddock. The cod stock is at a very low level. The stock of whiting has shown a continued decline over time but appears to be increasing again due to the reduction in fishing mortality. However, it is considered likely that the whiting stock is still outside safe biological limits. The saithe stock is now considered to be within safe biological limits. The stock of haddock presently profits from a good year class recruiting into the spawning stock, but the exploitation rate is still too high and the spawning stock is expected to decrease rapidly due to the very low recruitments, which followed the strong

1999 year class. Plaice and sole are outside safe biological limits and fishing mortality on both plaice and sole are high and unsustainable in the longer term. Norway pout and sandeel are short-lived species and their biomasses show large fluctuations in accordance with large variability of recruitment. The biomasses of Norway pout and sandeel in 2001 were high and these stocks are both considered within safe biological limits.

The herring stock in the North Sea collapsed in the mid1970s due to heavy exploitation, but has recovered after a closure of the fisheries between 1977 and 1981. In the mid-1990s it declined again. In 1996, effective management measures have been implemented to reduce the catches in both the human consumption and industrial fishery. These measures resulted in a considerable reduction in the fishing mortality in 19962001. Additionally, the North Sea autumn-spawning herring showed a very high recruitment over the last years. The stock has been outside safe biological limits for a number of years, but has recovered to above $\mathbf{B}_{\mathrm{pa}}$ and is expected to increase further. The herring stock is exploited in the North Sea and the Channel (Downs herring) by human consumption fisheries. By-catches of juvenile North Sea herring are taken in the industrial fishery for sprat in the North Sea and Division IIIa (Skagerrak/Kattegat). The sprat stock fluctuates considerably between years. The actual state of the sprat stock is not precisely known, but the biomass is thought to be high at present. The North Sea component of the North-East Atlantic mackerel stock collapsed in the early 1970s and shows no signs of recovery. Most of the mackerel catches taken in the northern North Sea in recent years originate from the western component.

Landings of cod in 2001 were 50000 t . The spawning stock in 2002 has been estimated at 38000 t , and has been decreasing rapidly over the last years. Recruitment has been below average since 1985 in all years, with the exception of the 1996 year class. The present assessment indicates a constant high fishing mortality in recent years. A recovery plan is urgently required to rebuild the stock.

The spawning stock of saithe (assessed for the North Sea and West of Scotland combined) is at a low level compared to the 1970s when it was more lightly exploited and recruitment was higher. In recent years it has increased slightly. Landings in 2001 in the North Sea were 95000 t . Fishing mortality has almost continuously declined from the 1980s. The proportion of the stock available in area VI has been reduced from the 1980s.

Human consumption landings of haddock in 2001 were 39000 t . Historically, the stock size has shown large variations due to the occasional occurrence of a very strong year class. The spawning stock size in 2001 has increased due to a large 1999 year class, but is expected to decrease rapidly due to a sequence of low recruitments after the strong 1999 year class. Fishing mortality remains too high.

The assessment of whiting has a lower precision than the assessment of some other stocks. Total landings have been gradually decreasing since 1976 and the landings in 2001, at 25000 t , are the lowest observed in the time-series. There are indications that the stock has increased in recent years but that it is likely still outside safe biological limits.

The spawning stock of plaice decreased in the early 1990s and in 1997 was at the lowest observed level historically. Landings have decreased since 1990 and were 82000 t in 2001. Fishing mortality has decreased but remains too high. At its present exploitation rate there is a high probability that the stock will remain below the levels observed in the 1970s and 1980s. The abundant 1996 year class was expected to increase the spawning stock, but a slower growth of this year class and increased discarding has reduced its contribution to the spawning stock.

Landings of sole were 20000 t in 2001. The spawning stock is decreasing. The spawning stock in recent years mainly consisted of a large 1996 year class which has now mostly passed the fishery. Fishing mortality has reduced in recent years but is still too high.

Landings of Norway pout have been low in 2001 at 66 000 t . The spawning stock in 2001 was amongst the highest in the time-series, due to the large 1999 year class. The 2000 year class, however, was poor and the stock is expected to decline fast. Fishing mortality has generally decreased between 1974-1995 and has fluctuated around a low level since.

Landings of sandeel in 2001 were 862000 t . Over the years, the spawning stock has been fluctuating without a trend. The spawning stock in 2001 was also around the long-term average. There is insufficient information to forecast the development of the stock in the short term.

The herring has recently recovered from a low and is currently considered to be above $\mathbf{B}_{\mathrm{pa}}$. The stock is expected to increase further in the short term due to the large 1998 year class which matures in 2002. Catches in the human consumption and industrial fisheries in the North Sea remained stable in the last three years and were 323000 t in 2001.

Landings of sprat in 2001 were 170000 t . The state of the sprat stock is not precisely known but appears to be high.

The spawning stock of mackerel in the North Sea remains small. Recruitment to this stock component has been very low for many years. An egg survey in 2002 estimated a slightly increasing spawning stock size. The fisheries for mackerel in the North Sea rely on a much larger stock component, the western mackerel, which spawns outside the North Sea and which is present in the northern North Sea in the second half of the year.

The present state of the North Sea horse mackerel stock is not known. The last estimate from egg surveys in 1989-1991 indicates an SSB of about 240000 t . The age composition of the relatively small catches suggests that the exploitation rate of juvenile fish may have increased in recent years.

The stock of Pandalus borealis in Division IVa (Norwegian Deep) and Division IIIa remains stable. The state of the stocks in Division IVa (Fladen Ground) and Division IVb (Farn Deep) is not known, as only insufficient data for assessments were available. The fishery in the latter two areas is opportunistic, strongly influenced by stock abundance and market prices.

## Management advice

Reductions in fishing mortalities have been advised for several stocks, which are outside safe biological levels. Fishing mortality is generally high and reached for most stocks the highest historical values in recent decades. This is in itself a clear indication of excessive effort.

This, and the poor performance of TACs, as implemented, in reducing fishing mortality, leads ICES to reiterate that the required reductions in fishing mortality can only be achieved if reductions in effort are included in management.

Most fisheries on roundfish and flatfish in the North Sea are characterised by extensive discarding. Discarding and high-grading also take place in pelagic fisheries, but little and incomplete information on discarding practices in these fisheries is available. Management measures, which reduce the amount of juveniles caught, would contribute to the recovery of spawning stocks and benefit yields.

Specific advice is presented in the respective stock sections.

## Mixed fisheries considerations

Many of the fleets in the North Sea operate on mixed aggregations of cod, haddock, and whiting, or mixed aggregations of sole, plaice, and cod (Table 3.5.1.3a). As trends in stocks of various species are generally not in synchrony, advice provided independently of the linkages between species may result in advised fishing mortalities that cannot be realized simultaneously within the context of mixed fisheries. This raises some concerns for stocks in need of special conservation efforts, such as those affected by recovery plans. For instance. If the reduction of fishing mortality (and effort) required for cod is used as a minimum reduction for the other species taken in a mixed fishery, TACs would have to be adjusted downward for some of the species in the mix. An alternative would be to adjust effort, perhaps on a fleet-by-fleet basis as per the proposed recovery plan, so as to meet the objectives of recovery efforts on cod.

## North Sea Commission Fisheries Partnership Assessment Consultations

In August 2002, the results of a number of assessments of stocks in the North Sea (cod, saithe, and plaice) were presented at assessment consultations with the North Sea Commission Fisheries Partnership. The meeting was held at ICES HQ. The chair of the Working Group on the Assessment of Demersal Stocks in the North Sea and Skagerrak (WGNSSK) presented the results of the assessments. Three independent scientific experts from the USA and Canada provided a scientific review of the assessments and representatives from a number of fishing organisations around the North Sea had the opportunity to exchange views with the ICES scientists about the state of the stocks and the development in the fisheries. The fishermen's representatives expressed general agreement with the assessment results for cod and saithe, but they had different views on the state of the plaice stock.

The Consultation Meeting met its main objectives of making the assessments more open and transparent, and identifying additional data that might improve the assessments. The presence of the independent experts reassured fishermen of the quality of the assessments and enabled all aspects of them to be explored. Fishermen opined that if the assessments were to become fully transparent then the format, presentation, and language of the assessment report would need to be modified. They also emphasised the need for care in describing the state of fish stocks.

Fishermen were prepared to assist with the provision of additional and improved information. Both they and the scientists saw advantages in fishermen being present at an early stage in the assessments to provide supporting information on the fisheries. Fishermen also pointed to the valuable information held in their log books, and urged that it be used. Scientists too benefited from the meeting and recognised the value of engaging with fishermen in the joint collection of data and in cooperative research. This initiative could be taken further through a Joint Partnership/ICES Study Group on Fishers' Information.

## Results of a survey among fishermen around the North Sea

The North Sea Commission Fisheries Partnership (NSCFP) has initiated a survey among fishermen fishing in the North Sea and in the waters west of Scotland. The fishermen were asked to compare the state of their catch in January to June 2002 with a similar period last year. Findings were based on the catch, not on the landings. The results are based on questions relating to the principal commercial species of the North Sea (cod, haddock, whiting, saithe, monkfish, Nephrops, plaice, and sole). For the purpose of the survey, the North Sea was subdivided into zones based upon ICES rectangles and consistent with the areas used for the International Bottom Trawl Survey (IBTS). The survey represents the
views of 778 fishermen operating across the North Sea. Results were presented graphically and in numbers, arranged by species. The results were both presented for the North Sea as a whole and by different areas in the North Sea.

ACFM drew the following observations from the data presented:

- Cod in the North Sea. The overall abundance of cod in the North Sea is unclear, with almost equal numbers of fishermen reporting more and less abundance of cod. The northern areas ( 1,7 , and 8 ) were noted to have more or much more cod, whereas in the southern areas most fishermen indicated that there was less or much less cod. This confirms the information from the research vessel surveys that indicated the same trends in distribution. The results are also similar to the results presented last year by the fisheries organizations.
- Haddock in the North Sea. The fishermen noted the abundance of the strong 1999 year class and reported having observed more or much more haddock in the North Sea. This trend is most obvious in the northern areas of the North Sea. The size range of the fish is mostly small fish, which is consistent with the strong year class.
- Whiting in the North Sea. Most responses in the southern and eastern areas of the North Sea indicated a higher stock size of whiting, whereas in the northern and western areas the fishermen experienced either the same or less whiting. This is consistent with the observations from the research surveys.
- Saithe in the North Sea. The abundance trend for saithe is not clear. Around $38 \%$ of the fishermen reported more or much more saithe, while $21 \%$ reported less or much less. According to the fishermen, saithe is mostly to be found in the northern-most areas, which is consistent with the results of the commercial CPUE series and the Norwegian acoustic survey.
- Plaice in the North Sea. According to the fishermen, catches in the southern areas of the North Sea have been more or much more according to $65 \%$ of the fishermen. $31 \%$ of the fishermen reported mostly small plaice. The perception of the fishermen is broadly consistent with the results of the research surveys and the assessment, although the absolute level of increase in the spawning stock that is indicated by the assessment may be less than can be derived from the fishermen's survey.
- Sole in the North Sea. Around 55\% of the fishermen indicated having seen either more or much more sole in the southern areas of the North Sea, which is the main area of distribution for this species. ACFM finds it difficult to match this with the results of the assessments, which indicates a slightly decreasing SSB. The difference may be caused by the fact that fishermen observe the catchable fish (total biomass), whereas the assessment concentrates on the mature fish (spawning stock).

## ACFM comments

ACFM welcomed the information presented by the NSC-FP and found the information useful. The spatial disaggregation provided makes it possible to track changes in the distribution of the fish stocks to the observations from the research surveys.

It is the policy of ICES to encourage and facilitate this sort of dialogue between scientists and the fishing industry. The documentation at this ACFM meeting is a very encouraging start to that process.

The enquiry indicates some diversity of opinions. Impressions of stocks vary between individual fishermen, but also between countries and areas.

The information on the status of fish stocks from the fishermen deals with abundance (in weight?) and with the size distribution in the catches. Comparisons are
short term, i.e. 1-3 years. There is only rarely a reference to the fishing mortality or a proxy thereof. The ICES assessment information is expressed in different ways, the SSB is often compared to $\mathbf{B}_{\mathrm{pa}}$ or $\mathbf{B}_{\mathrm{lim}}$, while the short-term trend is mostly not referred to. In order to compare the information these short-term trends have been inferred, based on the graphs of SSB presented in the advisory report.

The material provided by the industry will be sent to the relevant ICES assessment Working Groups for their consideration in the 2003 round of meetings.

In 2001 results of a similar survey were presented. Compared to that survey the 2002 exercise represents a significant improvement with respect to homogeneity of the questionaire and analysis. In analysing the results care should be taken that responses are biased towards the bigger vessels having a much higher response rate than smaller vessels, e.g. only $4 \%$ of the responses from the North Sea/Skagerrak/Kattegat are from vessels < 15 m . Also, the responses rate differs significantly between countries.

At present, the nature of the data provided means that they cannot be handled in a quantitative way, but the collection and reporting of quantitative data is a goal that both sides should work towards achieving. ICES and NSCFP has agreed to establish a joint study group that will work with the problems in such surveys. This group will consider and develop appropriate methods of collecting and reporting data.

Figure 3.5.1.1 Landings from North Sea. Data from Table 3.5.1.2.

### 3.5.2 <br> Cod in Subarea IV (North Sea), Division VIId (Eastern Channel), and Division IIIa (Skagerrak)

State of stock/exploitation: The stock is outside safe biological limits. The spawning stock is estimated to have been below $\mathbf{B}_{\mathrm{pa}}$ since 1984 and in the region of $\mathbf{B}_{\text {lim }}$ since 1990. SSB in 2001 is estimated at a new historic low at about 30000 t and is now estimated $50 \%$ lower than last year. The SSB in 2002 is estimated around 38 000 t . Fishing mortality has remained at about the historic high and above $\mathbf{F}_{\mathrm{pa}}$ since the early 1980s and F in 2001 is estimated to be above $\mathbf{F}_{\text {lim }}$. Except for the 1996 year class, recruitment has been below average in all years since 1987. The 1997 and 2000 year classes are estimated to be the poorest on record.

Management objectives: In 1999 the EU and Norway have "agreed to implement a long-term management plan for the cod stock, which is consistent with the precautionary approach and is intended to constrain harvesting within safe biological limits and designed to provide for sustainable fisheries and greater potential yield. The plan shall consist of the following elements:

1. Every effort shall be made to maintain a minimum level of SSB greater than $70000 t\left(\boldsymbol{B}_{\text {lim }}\right)$.
2. For 2000 and subsequent years the Parties agreed to restrict their fishing on the basis of a TAC
consistent with a fishing mortality rate of 0.65 for appropriate age groups as defined by ICES.
3. Should the SSB fall below a reference point of $150000 t\left(\boldsymbol{B}_{p a}\right)$, the fishing mortality referred to under paragraph 2 shall be adapted in the light of scientific estimates of the conditions then prevailing. Such adaptation shall ensure a safe and rapid recovery of $S S B$ to a level in excess of $150000 t$
4. In order to reduce discarding and to enhance the spawning biomass of cod, the Parties agreed that the exploitation pattern shall, while recalling that other demersal species are harvested in these fisheries, be improved in the light of new scientific advice from, inter alia, ICES.
5. The Parties shall, as appropriate, review and revise these management measures and strategies on the basis of any new advice provided by ICES."

ICES considers that the agreed Precautionary Approach reference points in the management plan are consistent with the precautionary approach, provided they are used as upper bounds on F and lower bounds on SSB, and not as targets.

Precautionary Approach reference points (unchanged since 1999):

| ICES considers that: | ICES proposes that: |
| :--- | :--- |
| $\mathbf{B}_{\text {lim }}$ is 70000 t , the lowest observed spawning stock <br> biomass. | $\mathbf{B}_{\mathrm{pa}}$ be set at 150000 t. This is the previously agreed <br> MBAL and affords a high probability of maintaining |
| SSB above $\mathbf{B}_{\text {lim }}$, taking into account the uncertainty of |  |
| assessments. Below this value the probability of below- |  |
| average recruitment increases. |  |

Technical basis:

| $\mathbf{B}_{\text {lim }}=$ Rounded $\mathbf{B}_{\text {loss }}=70000 \mathrm{t}$. | $\mathbf{B}_{\mathrm{pa}}=$ Previous MBAL and signs of impaired recruitment <br> below: 150000 t. |
| :--- | :--- |
| $\mathbf{F}_{\text {lim }}=\mathbf{F}_{\text {loss }}=0.86$. | $\mathbf{F}_{\mathrm{pa}}=$ Approx. $5^{\text {th }}$ <br> equilibrium bercentile of $\mathrm{F}_{\text {loss }} ;$ implies an <br> probability that $\left(\mathrm{SSBMT}<\mathbf{B}_{\mathrm{pa}}\right.$ and a less than $10 \%$ |

Advice on management: Given the very low stock size, the recent poor recruitments, and continued high fishing mortality despite management efforts to promote stock recovery, ICES recommends a closure of all fisheries for cod as a targeted species or bycatch. In fisheries where cod comprises solely an incidental catch there should be stringent restrictions on the catch and discard rates of cod, with effective monitoring of compliance with those restrictions.

These and other measures that may be implemented to promote stock recovery should be kept in place until there is clear evidence of the recovery of the stock to a size associated with a reasonable probability of good recruitment and there is evidence that productivity has improved. The current SSB is so far below historic stock sizes that both the biological dynamics of the stock and the behavior of the fleets are unknown, and therefore historic experience and data are not considered a reliable basis for medium-

## term forecasts of stock dynamics under various rebuilding scenarios.

## Relevant factors to be considered in management:

Although large short-term losses will be incurred in many North Sea fisheries, the advised measures are required if the cod stock is to reach a level where it can regain historic productivity. The advice will likely result in greatly reduced harvesting of other stocks where the fisheries take cod as part of a mixed-species fisheries, particularly haddock, whiting. Harvesting of other stocks such as plaice, sole, and Nephrops may also require substantial reductions and/or changes in times, areas or methods fished, if it is shown that, in recent years, a significant proportion of the annual cod catch has been caught in the fisheries for them. However, the current state of the cod stock, and the failure of past measures to bring fishing mortality down to rates that allow rebuilding, mean that more stringent action is required.

Time and area closures for particular fisheries may be a tool in rebuilding this stock, and their effect can be considered in evaluating harvest opportunities for other species.

ICES notes that this advice presents a strong incentive to fisheries to avoid catching cod. If industry-initiated programs can be demonstrated to bring their catch rates of cod in fisheries for other species down to near zero,
then these programs could be considered in management of such fisheries. Industry-initiated programs to pursue such incentives should be encouraged, but must include fully transparent method for ensuring that their catches of cod are fully and credibly reported.

The newly agreed increases in minimum mesh size for North Sea fisheries, if implemented fully, would have a positive effect on the exploitation pattern of North Sea cod when fisheries taking cod eventually reopen. However, the implementation and enforcement of these measures has not been evaluated yet.

North Sea demersal fisheries have been subjected to a number of EU and national regulations designed to modify the selectivity of fishing gears. No complete evaluation of their likely impacts has yet been undertaken, but an overview of their potential effects is available based upon a number of simplifying assumptions. This overview considers measures outlined in EU regulations 850/98 and 2056/2001, and UK measures SSI 227/2000, SSI 250/2001 and SI $649 / 2001$. Results are expressed as the percentage deviation from baseline simulations, which assume that no selectivity changes occur. The results are considered to be indicative of the likely impacts. The simulations are made assuming single-species population dynamics and assuming full and effective implementation of the measures, i.e. that all fleets catching cod are subject to the full impact of the measures. For 2002 it is assumed that all UK vessels have adopted the 110 mm mesh size derogation of EU regulation 2056/2001 and that $20 \%$ of non-UK fleets have adopted it. For 2003 no such derogation is assumed to apply.

| Year | Landings for human <br> consumption | Discards | Industrial by-catch | Spawning stock <br> biomass |
| :---: | :---: | :---: | :---: | :---: |
| 2002 | $<1 \%$ | - | - |  |
| 2003 | $<1 \%$ | - | - | $<1 \%$ |
| Long Term | $7 \%$ | - | - | $5 \%$ |

The absence of information on discards in the cod assessment and forecasts means that the effect of increased selectivity at the youngest ages is not accounted for in the above table.

The effects of the emergency closure implemented in 2001 has not been evaluated by ICES, but that closure was likely to have contributed little to the recovery of the stock.

In recent years the growth rate of North Sea cod has declined. The reasons for this are not known, but if
growth remains slow, the rate of recovery of SSB will be delayed. Slower growth may also expose juveniles longer to discarding.

The catches of this stock in Division VIId is managed by TAC covering Divisions VIIb-k,VIII, IX, X and CECAF 34.1.1. Managers should take this into account when setting a TAC for Divisions VIIb-k,VIII, IX, X and CECAF 34.1.1.

Catch forecast for 2003:

Weights in ' 000 t .
Shaded scenarios considered inconsistent with the precautionary approach.

Landings by Division or Subarea are obtained by prorating the combined area catch by 0.122 for Division IIIa, 0.851 for Subarea IV, and 0.027 for Division VIId. These factors are the ratio of the mean catches by area to the combined area for the period 1992-1996.

Rebuilding plan: A rebuilding plan for the cod stock in the North Sea has recently been proposed by the European Commission. Although ICES advises a closure and not a rebuilding plan with lowered fishing on cod, it did conduct a review of the proposed plan. The proposal consists of a set of measures that aim at increasing the spawning stock biomass by $30 \%$ per year. This is to be achieved by reductions in fishing mortalities and maximum allowed changes in TACs. The reductions in fishing mortalities are to be accompanied by reductions in fishing effort.

The rebuilding plan has been evaluated by the Scientific, Technical and Economic Committee on Fisheries (STECF) and by the Working Group on the Assessment of Demersal Stocks in the North Sea and Skagerrak (WGNSSK). The evaluations indicate that the proposed recovery plan is likely to lead to a recovery period of at least 8 years. It was further noted that evaluations were sensitive to the assumptions used so that the actual number of years required for recovery cannot be estimated precisely. Notably, the bias in the assessment may seriously alter the perception of recovery to a period in the order of 12 years. Discards have not been included in the evaluation, which limits the generality of the results. ICES also notes that the current SSB is so far below historic stock sizes that both the biological dynamics of the stock and the behavior of the fleets are unknown, and therefore historic experience and data are not considered a reliable basis for mediumterm forecasts of stock dynamics under various rebuilding scenarios. On the basis of this evaluation ICES concludes that the proposed rebuilding plan cannot be accepted as likely to lead to safe and rapid rebuilding of this cod stock.

Comparison with previous assessment and advice: Fishing mortality has consistently been underestimated and stock size overestimated in previous assessments, and the current assessment suffers from the same problem. The quality of the assessment improved in 2000 and 2001 due to the exclusion of commercial CPUE data. This year the assessment again showed retrospective bias, possibly because of a decrease in the quality of the landings data in 2001.

Elaboration and special comment: Cod are taken by towed gears in mixed roundfish fisheries, which include haddock and whiting. They are also taken in directed fisheries using fixed gears. By-catches of cod occur in flatfish and shrimp fisheries especially in the Southern North Sea and in Nephrops fisheries. Average landings by fleet segment in the North Sea demersal fisheries are shown in Table 3.5.1.3 (see overview Section 3.5.1). The average landings allow a comparison to be made between different fleet segments. However, the interpretation of Table 3.5.1.3 is hindered by the fact that discards are not included in the table so that the actual catch of the different fleet segments cannot be evaluated. A STECF subgroup will meet shortly after ACFM to address the issue of linkage in the cod-haddock-whiting fishery and ICES working groups are expected to deliver data to this group. The issue of linkage will also be an explicit term of reference for an ICES study group, which is expected to meet next year.

It was apparent that commercial CPUE data used in calibrating previous assessments had a strong tendency to give a more optimistic estimate of the state of the stock than research vessel survey data. There are a number of reasons for believing that the commercial CPUE data may be biased. For example, there have been substantial changes in the distribution of commercial fleet effort and the nature of vessels in the fleet, which may affect abundance indices derived from these sources. In addition, commercial fleets may target areas of high cod abundance leading to artificially higher abundance estimates. It should be noted that
differing signals between commercial CPUE data and survey data affected assessments of some Canadian cod stocks, resulting in an over-optimistic decision on the management of these stocks before they collapsed. In view of these problems, no commercial CPUE data are used in the assessment of North Sea cod.

A number of analyses were performed using a variety of different assessment models. All these approaches gave very similar results. While no method is without uncertainty, the fact that a variety of methods give comparable results increases confidence in the current assessment.

There is reason to suspect that the landings for 2001 were under-reported. The TAC implied a reduction in fishing mortality to the order of $50 \%$, and the reported landings were less than the TAC. The results of a time-series analysis indicated predicted removals in 2001 almost double the reported landings.

The North Sea Commission Fisheries Partnership has reviewed the assessment for North Sea cod in August 2002. The review consisted of a scientific review by three independent scientific experts and a public review with the participation of fishermen organizations. The general conclusion of the review was that the assessment was carried out according to appropriate standards. The fishermen broadly shared the perception on the development in the stock.

Following the review by the North Sea Commission Fisheries Partnership a survey has been conducted among fishermen in order to evaluate their perceptions of the stock and catches in 2002 in relation to 2001. The results of that survey were made available to ACFM and indicated that fishermen differ in their perception of stock abundance. Fishermen in the North tend to see more fish than last year, and fishermen in the South tend to see fewer fish.

The assessment is based on analysis of catch-at-age data calibrated with data from three research vessel surveys.

| Average | 356825 | 145533 | 196594 | 0.7842 |

State of stock/exploitation: The stock is being harvested outside safe biological limits. SSB in 2002 is estimated to be above the $\mathbf{B}_{\mathrm{pa}}$, and fishing mortality in 2001 is estimated to be above the $\mathbf{F}_{\mathrm{pa}}$. The 1999 year class is estimated to be strong and has led to the current increase of SSB, but it is the only year class above average size for a number of years and dominates both the stock biomass and the catches. The 2001 year class is the lowest on record and the 2002 year class also appears to be well below average. The SSB is expected to decrease to below $\mathbf{B}_{\mathrm{pa}}$ in the short term at the present fishing mortality rates.

Management objectives: In 1999 the EU and Norway have "agreed to implement a long-term management plan for the haddock stock, which is consistent with the precautionary approach and is intended to constrain harvesting within safe biological limits and designed to provide for sustainable fisheries and greater potential yield. The plan shall consist of the following elements:

1. Every effort shall be made to maintain a minimum level of SSB greater than $100000 t\left(\boldsymbol{B}_{\text {lim }}\right)$.
2. For 2000 and subsequent years the Parties agreed to restrict their fishing on the basis of a TAC
consistent with a fishing mortality rate of 0.70 for appropriate age groups as defined by ICES.
3. Should the SSB fall below a reference point of $140000 t\left(\boldsymbol{B}_{p a}\right)$, the fishing mortality referred to under paragraph 2 shall be adapted in the light of scientific estimates of the conditions then prevailing. Such adaptation shall ensure a safe and rapid recovery of SSB to a level in excess of $140000 t$.
4. In order to reduce discarding and to enhance the spawning biomass of haddock, the Parties agreed that the exploitation pattern shall, while recalling that other demersal species are harvested in these fisheries, be improved in the light of new scientific advice from, inter alia, ICES.
5. The Parties shall, as appropriate, review and revise these management measures and strategies on the basis of any new advice provided by ICES."

ICES considers that the agreed Precautionary Approach reference points in the management plan are consistent with the precautionary approach, provided they are used as upper bounds on F and lower bounds on SSB, and not as targets.

Precautionary Approach reference points (unchanged since 1999):

| ICES considers that: | ICES proposes that: |
| :--- | :--- |
| $\mathbf{B}_{\text {lim }}$ is 100000 t, the bootstrapped median estimate of the <br> lowest observed biomass. | $\mathbf{B}_{\text {pa }}$ be set at 140 000 t. This affords a high probability of <br> maintaining SSB above $\mathbf{B}_{\text {lim }}$, taking into account the <br> uncertainty of the assessments. |
| $\mathbf{F}_{\text {lim }}$ is 1.0, a fishing mortality historically associated with <br> stock decline. | $\mathbf{F}_{\text {pa }}$ be set at 0.7. This F is considered to provide <br> approximately 90\% probability of avoiding a fishing <br> mortality associated with stock collapse. |

Technical basis:

| $\mathbf{B}_{\text {lim }}=$ Smoothed $\mathbf{B}_{\text {loss. }}$ | $\mathbf{B}_{\mathrm{pa}}=1.4^{*} \mathbf{B}_{\text {lim. }}$. |
| :--- | :--- |
| $\mathbf{F}_{\text {lim }}=\mathbf{F}_{\text {loss }}$ poorly defined; 1.4 $\mathbf{F}_{\mathrm{pa}}$ which has historically <br> led to decline: 1.0. | $\mathbf{F}_{\mathrm{pa}}=\mathrm{F}_{\mathrm{lpg}}{ }^{1}$ implies an equilibrium biomass $>\mathbf{B}_{\mathrm{pa}}$ and a <br> less than $10 \%$ probability that $\left(\mathrm{SSB}_{\mathrm{MT}}<\mathbf{B}_{\mathrm{pa}}\right)$. |

${ }^{\mathrm{I}} \mathrm{F}_{\text {lpg }}$ is defined as the F value having a $10 \%$ probability of giving a replacement line above $\mathrm{G}_{\text {loss }}$, which is the slope in the stock-recruitment plot associated with the lowest observed SSB.

#### Abstract

Advice on management: Since haddock is mostly taken in demersal fisheries with cod and whiting, the advice for cod determines the advice for haddock. Unless ways to harvest haddock without by-catch or discards of cod can be demonstrated fishing for haddock should not be permitted.

Relevant factors to be considered in management: On the basis of the status of haddock alone, ICES would recommend that the fishing mortality be less than $\mathrm{F}=$ 0.52 to ensure that the stock remains above $\mathbf{B}_{\mathrm{pa}}$ in 2004
and 2005. This would correspond to landings of less than 84000 t in 2003 and a reduction of fishing mortality by at least $40 \%$. If any fisheries on haddock are permitted, despite the advice on cod, then total catches should not exceed these values.

The extent to which the cod-haddock-whiting fisheries are linked has not been quantified. This linkage is not one-to-one, but it is evident and probably variable. It is possible for fishing vessels to increase their targeting of individual species within the demersal fish complex, but
there will always be a significant by-catch of other roundfish.

ICES notes that this advice presents a strong incentive to fisheries to avoid catching cod. If industry-initiated programs can be demonstrated to bring their catch rates of cod in fisheries for haddock down to near zero, then these programs could be considered in management of these fisheries. Industry-initiated programs to pursue such incentives should be encouraged, but must include a high rate of independent observer coverage, or other fully transparent method for ensuring that their catches of cod are fully and credibly reported.

Recruitment of haddock has been well below average for all year classes after the strong 1999 year class. This will have a strong negative impact on the development of the spawning stock biomass in the near future. These weak year classes mean that a reduction of fishing mortality to 0.52 would be necessary in order to ensure that the stock remains above $\mathbf{B}_{\mathrm{pa}}$ in the short and medium term.

Fisheries targeting Nephrops may take a by-catch of haddock. In this case ICES notes that haddock may continue to be caught subject to existing EU regulations applying to Nephrops fisheries, and providing the catch of cod complies with the advice on cod.

Average landings by fleet segment in the North Sea demersal fisheries are shown in Table 3.5.1.3 (see overview Section 3.5.1). The average landings allow a comparison to be made between different fleet segments. However, the interpretation of Table 3.5.1.3 is hindered by the fact that discards are not included in the table so that the actual catch of the different fleet segments cannot be evaluated. A STECF subgroup will meet shortly after ACFM to address the issue of linkage in the cod-haddock-whiting fishery, and ICES working groups are expected to deliver data to this group. The
issue of linkage will also be an explicit term of reference for an ICES study group, which is expected to meet next year.

Haddock, while a principal target for some fleets, are taken in a mixed roundfish fishery. This means it is important to take into account the impact of management of haddock on other stocks, notably cod and whiting. The reverse is, of course, also true. Recent measures to protect North Sea cod, such as the closed area, and agreements to increase mesh size, will affect the haddock fishery. Improvements in selectivity related to measures to protect cod should, if effectively implemented, benefit the haddock fishery by reducing discards and increasing landings in the long term.

Several technical conservation measures have been or will be implemented from 2000 onwards. The effects of these measures have not yet been demonstrated in the available data. North Sea demersal fisheries have been subjected to a number of EU and national regulations designed to modify the selectivity of fishing gears. No complete evaluation of their likely impacts has yet been undertaken, but an overview of their potential effects is available based upon a number of simplifying assumptions. This overview considers measures outlined in EU regulations 850/98 and 2056/2001, and UK measures SSI 227/2000, SSI 250/2001, and SSI $649 / 2001$. Results are expressed as the percentage deviation from baseline simulations that assume no selectivity changes occur. The results are considered to be indicative of the likely impacts. The simulations are made assuming single-species population dynamics and assuming full and effective implementation of the measures, i.e. that all fleets catching cod are subject to the full impact of the measures. For 2002 it is assumed that all UK vessels have adopted the 110 mm mesh size derogation of EU regulation 2056/2001 and that $20 \%$ of non-UK fleets have adopted it. For 2003 no such derogation is assumed to apply.

Weights in ' 000 t . ${ }^{1}$ North Sea + IIIa human consumption. ${ }^{2}$ Multipliers on $\mathbf{F}_{\mathrm{sq}}$ refer to human consumption and discard partial fishing mortality only. By-catch F is assumed constant at 0.05. The landings in Division IIIa are calculated as 3.3\% of the combined area total. The figure $3.3 \%$ is the long-term average of the Division IIIa (human consumption) landings expressed as a percentage of the combined IIIa-IV (human consumption) landings.

* The shading is presented solely with regard to a precautionary approach to haddock. It is the requirement for the recovery of cod that leads to the advice of no harvesting of haddock.
Shaded scenarios considered inconsistent with the precautionary approach.

Medium- and long-term projections: The mediumterm analysis indicate that the stock is expected to decline rapidly at the current fishing mortality ( $\mathrm{F}(2001$ ) $=0.83$ ) due to the very low recruitments since 1999 .

Comparison with previous assessment and advice: Assessments carried out since 1997 showed a strong tendency to overestimate SSB and underestimate fishing mortality. The retrospective analysis of the current assessment indicates that this problem has been reduced.

Elaboration and special comment: The large majority of the catch is taken by Scottish trawlers, seiners, and pair trawlers. Smaller quantities of haddock are taken by other vessels, including Nephrops trawlers. In Division IIIa, catches are taken by trawl, seine, and gillnet in mixed fisheries.

In the early 1990s the industrial by-catch of haddock has frequently been overestimated in the short-term predictions. Three potential sources could lead to overestimating the industrial by-catch in the catch predictions: population size at the start of the prediction, mean weight-at-age, and partial fishing mortality. These sources of bias have been evaluated and indicate that
none of these sources can be identified uniquely as the source of bias. The problem of overestimating industrial by-catch of haddock appears to be relatively small in relation to the uncertainty of the assessment.

The analytical assessment is based on a long time-series of catch-at-age data using CPUE from survey fleets for calibration.

Source of information: Report of the Working Group on the Assessment of Demersal Stocks in the North Sea and Skagerrak, 11 - 20 June 2002 (ICES CM 2003/ACFM: 02 ).

## Medium-term analysis at $\mathrm{F}_{\mathrm{sq}}=\mathbf{0 . 8 3}$.

Haddock,North Sea and IIIa. Medium term analysis, 1.00*Fsq. Number of simulation

Probability of SSB falling below $\mathbf{B}_{\mathrm{pa}}$ (140 thousand tonnes) at different levels of fishing mortality, held constant over the 10 year period.

State of stock/exploitation: The stock is outside safe biological limits. SSB has declined over the last 20 years, reaching a historic low in 1998. Fishing mortality has decreased and is below $\mathbf{F}_{\mathrm{pa}}$. Recruitment has fluctuated
below the average (1980-2001) level since 1990, with the exception of the 1998 year class.

Management objectives: No explicit management objectives are set for this stock.

Precautionary Approach reference points (unchanged since 1999):

| Precautionary Approach reference points (unchanged since 1999): |
| :--- |
| ICES considers that: |
| $\mathbf{B}_{\text {lim }}$ is 225000 t , the lowest observed biomass. |
| ICES proposes that: |
| $\mathbf{F}_{\text {lim }}$ is 0.90 , the fishing mortality estimated to lead to <br> potential stock collapse. |
| $\mathbf{B}_{\mathrm{pa}}$ be set at 315000 t. This affords a high probability of <br> maintaining SSB above $\mathbf{B}_{\text {lim }}$, taking into account the <br> uncertainty of assessments. Below this value the <br> probability of below-average recruitment increases. |

Technical basis:

| $\mathbf{B}_{\text {lim }}=\mathbf{B}_{\text {loss }}=225000 \mathrm{t}$. | $\mathbf{B}_{\mathrm{pa}}=1.4^{*} \mathbf{B}_{\text {lim }}$, apparent impaired recruitment below this <br> value: 315000 t. |
| :--- | :--- |
| $\mathbf{F}_{\text {lim }}=\mathbf{F}_{\text {loss }}=0.9$. | $\mathbf{F}_{\mathrm{pa}} \sim 0.7 \mathbf{F}_{\text {lim }}=0.65$. |

Advice on management: Since whiting is mostly taken in demersal fisheries with cod and haddock, the advice for cod determines the advice for whiting. Except where it can be demonstrated that whiting can be harvested without by-catch or discards of cod, fishing for whiting should not be permitted.

Relevant factors to be considered in management: Demonstration that whiting can be taken without cod should be based on a high rate of independent observer coverage, or other fully transparent methods for ensuring that their catches of cod are fully and credibly reported.

On the basis of the status of whiting alone, in order to bring SSB above $\mathbf{B}_{\mathrm{pa}}$ in 2004, ICES would recommend that fishing mortality in 2002 should be below 0.27 , corresponding to human consumption landings of less than $26 \mid 000 \mathrm{t}$. This implies a reduction in fishing mortality of at least $40 \%$. If fishing on whiting is permitted consistent with the advice on cod then total catches should not exceed these values.

The recommended reduction in fishing mortality cannot be achieved by TAC management alone, because whiting is caught in a mixed demersal fisheries, where discarding of whiting is sometimes high (commonly $60 \%$ by weight). In Nephrops, shrimp, and flatfish fisheries nearly all whiting caught are discarded. Average landings by fleet segment in the North Sea demersal fisheries are shown in Table 3.5.1.3 (see overview Section 3.5.1). The average landings allow a comparison to be made between different fleet segments. However, the interpretation of Table 3.5.1.3 is hindered by the fact that discards are not included in the table so that the actual catch of the different fleet segments cannot be
evaluated. A STECF subgroup will meet shortly after ACFM to address the issue of linkage in the cod-haddock-whiting fishery, and ICES working groups are expected to deliver data to this group. The issue of linkage will also be an explicit term of reference for an ICES study group, which is expected to meet next year.

A reduction in TAC without a reduction in effort is likely to result in increased discarding, which may counteract the desired reduction in fishing mortality. For mixed demersal fisheries improvements to gear selectivity, such as increased mesh size or inclusion of square mesh panels, would contribute to this goal.

North Sea demersal fisheries have been subjected to a number of EU and national regulations designed to modify the selectivity of fishing gears. No complete evaluation of their likely impacts has yet been undertaken, but an overview of their potential effects is available based upon a number of simplifying assumptions. This overview considers measures outlined in EU regulations 850/98 and 2056/2001, and UK measures SSI 227/2000, SSI 250/2001 and SI $649 / 2001$. Results are expressed as the percentage deviation from baseline simulations, which assume that no selectivity changes occur. The results are considered to be indicative of the likely impacts. The simulations are made assuming single-species population dynamics and assuming full and effective implementation of the measures, i.e. that all fleets catching cod are subject to the full impact of the measures. For 2002 it is assumed that all UK vessels have adopted the 110 mm mesh size derogation of EU regulation 2056/2001 and that $20 \%$ of non-UK fleets have adopted it. For 2003 no such derogation is assumed to apply.

| Year | Landings for human <br> consumption | Discards | Industrial bycatch | Spawning stock <br> biomass |
| :---: | :---: | :---: | :---: | :---: |
| 2002 | $-66 \%$ | $-88 \%$ | $6 \%$ |  |
| 2003 | $-72 \%$ | $-93 \%$ | $16 \%$ | $13 \%$ |
| Long Term | $-42 \%$ | $-91 \%$ | $26 \%$ | $57 \%$ |

ICES notes that improvement in SSB whiting may be achieved through implementation of technical conservation measures for cod, because whiting are taken in a mixed fishery with cod. Hence, the
rebuilding of whiting SSB could be somewhat greater if the advice on North Sea cod and measures to reduce discarding are implemented effectively.

## Catch forecast for 2003*:

Basis: $\mathrm{F}(2002)=\mathbf{F}_{\mathrm{sq}}=\mathrm{F}(01)=0.43$; HC landings IV (2002) $=31.7$; HC landings VIId (2002) $=4.1$; Discards (2002) $=$ 18.4; Industrial by-catch $(2002)=6.1 ; \operatorname{SSB}(2003)=270$.

Weights in ' 000 tonnes. The HC landings in Division VIId are calculated as $11.5 \%$ of the HC landings forecast for the area combined, $11.5 \%$ being the average of the VIId HC landings relative to the HC landings from the combined area for the years 1992-1996.

* The shading is presented solely with regard to a precautionary approach to whiting. It is the requirement for the recovery of cod that leads to the advice of no harvesting of whiting.
Shaded scenarios considered inconsistent with the precautionary approach.

Medium- and long-term projections: No medium- or long-term projections have been carried out.

Comparison with previous assessment and advice: The results of the current assessment are broadly consistent with last year's assessment, although fishing mortality has been revised upwards for a number of years. The reason for this revision is the addition of the 2001 data.

Elaboration and special comment: At very low stock sizes, as experienced in recent years, catch opportunities in the short term are very dependent on the strength of incoming year classes. However, the estimates of year class strength for whiting are very imprecise.

The SSB is estimated to have increased since 1998, mainly due to lower fishing mortality, not increased recruitment.

There are inconsistencies between information from commercial catch data and survey data. There are also inconsistencies between information from different surveys which may reflect different abundance trends between areas. Discard data are available for about $50 \%$ of the catch since 1975, but the discard estimates are relatively imprecise due to low sampling effort.

In the early 1990s the industrial by-catch of whiting has frequently been overestimated in the short-term
predictions. Three potential sources could lead to overestimating the industrial by-catch in the catch predictions: population size at the start of the prediction, mean weight-at-age, and partial fishing mortality. These sources of bias have been evaluated and indicate that both the mean weight-at-age and the fishing mortality on the industrial by-catch components have been overestimated in those years. The problem of overestimating industrial by-catch appears to have decreased in the second half of the 1990s.

Analytical assessment (time-series analysis) based on landings, discards, and industrial by-catch data-at-age data. No calibration data included in the assessment.

|  |  |  |  |  |

State of stock/exploitation: The stock is within safe biological limits. Fishing mortality has declined from 1986 to 2001, and is estimated below $\mathbf{F}_{\mathrm{pa}}$ in 2001. SSB has remained near or below $\mathbf{B}_{\mathrm{pa}}$ since 1984, but it has increased in the late 1990s and is estimated to be above $\mathbf{B}_{\mathrm{pa}}$ since 1999.

Management objectives: In 1999 the EU and Norway have "agreed to implement a long-term management plan for the saithe stock, which is consistent with the precautionary approach and is intended to constrain harvesting within safe biological limits and designed to provide for sustainable fisheries and greater potential yield. The plan shall consist of the following elements:

1. Every effort shall be made to maintain a minimum level of SSB greater than $106000 t\left(\boldsymbol{B}_{\text {lim }}\right)$.
2. For 2000 and subsequent years the Parties agreed to restrict their fishing on the basis of a TAC
consistent with a fishing mortality rate of 0.40 for appropriate age groups as defined by ICES.
3. Should the SSB fall below a reference point of $200000 t\left(\boldsymbol{B}_{p a}\right)$, the fishing mortality referred to under paragraph 2 shall be adapted in the light of scientific estimates of the conditions then prevailing. Such adaptation shall ensure a safe and rapid recovery of SSB to a level in excess of 200000 t .
4. The Parties shall, as appropriate, review and revise these management measures and strategies on the basis of any new advice provided by ICES."

ICES considers that the agreed Precautionary Approach reference points in the management plan are consistent with the precautionary approach, provided they are used as upper bounds on F and lower bounds on SSB, and not as targets.

Precautionary Approach reference points (unchanged since 1999):

| ICES considers that: | ICES proposes that: |
| :--- | :--- |
| $\mathbf{B}_{\text {lim }}$ is 106000 t. | $\mathbf{B}_{\mathrm{pa}}$ be set at 200000 t. |
| $\mathbf{F}_{\text {lim }}$ is 0.60. | $\mathbf{F}_{\mathrm{pa}}$ be set at 0.40. |

Technical basis:

| $\mathbf{B}_{\text {lim }}=\mathbf{B}_{\text {loss }}=106000 \mathrm{t}$. | $\mathbf{B}_{\mathrm{pa}}$ Impaired recruitment at SSB less than 200000 t . This affords a high probability of maintaining SSB above $\mathbf{B}_{\text {lim }}$, taking into account the uncertainty of assessments. Below this value the probability of belowaverage recruitment increases. |
| :---: | :---: |
| $\mathbf{F}_{\text {lim }}=\mathbf{F}_{\text {loss }}=0.6$, the fishing mortality estimated to lead to potential stock collapse. | $\mathbf{F}_{\mathrm{pa}}=5^{\text {th }}$ percentile of $\mathbf{F}_{\text {loss }}(0.45)$ implies that $\mathrm{B}_{\mathrm{eq}}<\mathbf{B}_{\mathrm{pa}}$. F $=0.4$ implies that $\mathrm{B}_{\mathrm{eq}}>\mathbf{B}_{\mathrm{pa}}$ and $\mathrm{P}\left(\mathrm{SSB}_{\mathrm{MT}}<\mathbf{B}_{\mathrm{pa}}\right)<10 \%$. This F is considered to provide approximately $95 \%$ probability of avoiding $\mathbf{F}_{\text {lim }}$, taking into account the uncertainty of the assessment. |

Advice on management: ICES advises that fishing mortality in 2003 should be less than $F_{p a}$, corresponding to landings in 2003 of less than 193000 t.

Relevant factors to be considered in management: There is no long-term gain in yield by increasing current fishing mortality. Restricting landings to 132 000 t would maintain status quo fishing mortality and would increase stability of catches in the medium term.

Before 1999, saithe in Subarea VI and saithe in Sub-rea IV and Division IIIa were assessed as two separate
stocks. The ICES advice applies to the combined areas IIIa, IV, and VI.

The assessment is considered to be uncertain because there are few survey data to confirm the stock trends as calibrated by commercial CPUE. The catch forecast is mainly driven by the assumption of average recruitment, with about one quarter of the forecast 2003 landings and 2004 SSB originating from this assumption. This means that the forecasts may not track fluctuations in the stock particularly well. Medium-term considerations indicate that continued fishing at $\mathbf{F}_{\text {sq }}$ implies low probability of falling below $\mathbf{B}_{\mathrm{pa}}$.

Catch forecast for 2003:
Basis: $\operatorname{TAC}(2002)=\operatorname{Landings}(2002)=149 ; \mathrm{F}(2002)=0.29 ; \mathrm{SSB}(2003)=325$.

| F(2003 onwards) | Basis | Total Landings |  <br> IV $^{*}(2003)$ | Landings VI <br> $(2003)$ | SSB(2004) |
| :---: | :---: | :---: | :---: | :---: | :---: |
| 0.15 | $0.6 * \mathbf{F}_{\mathrm{sq}}$ | 84 | 76.4 | 7.6 | 386 |
| 0.20 | $0.8 * \mathbf{F}_{\mathrm{sq}}$ | 109 | 99.2 | 9.8 | 361 |
| 0.25 | $1.0 * \mathbf{F}_{\mathrm{sq}}$ | 132 | 120.1 | 11.9 | 338 |
| 0.30 | $1.2 * \mathbf{F}_{\mathrm{sq}}$ | 153 | 139.2 | 13.8 | 317 |
| 0.34 | $1.4 * \mathbf{F}_{\mathrm{sq}}$ | 173 | 157.4 | 15.6 | 297 |
| 0.40 | $1.61^{*} \mathbf{F}_{\mathrm{sq}}\left(=\mathbf{F}_{\mathrm{pq}}\right)$ | 193 | 175.6 | 17.4 | 277 |
| 0.44 | $1.8 * \mathbf{F}_{\mathrm{sq}}$ | 211 | 192.0 | 19.0 | 261 |

Weights in ' 000 t .
Shaded scenarios considered inconsistent with the precautionary approach.
*Landings split according to average in 1993-1998.

Medium- and long-term projections: Results of the medium-term analysis indicate that under the status quo fishing mortality there is a low probability of falling below $\mathbf{B}_{\mathrm{pa}}$ in the medium-term.

## Comparison with previous assessment and advice:

 This assessment gives a new estimate of fishing mortality in 2000 which is $11 \%$ lower than the estimate from last year, and estimates of SSB in 2000 and 2001 which are respectively $6 \%$ lower and higher compared to the estimates from last year. The general tendency of this assessment to overestimate F and underestimate SSB appears to be reduced.Elaboration and special comment: Saithe in the North Sea are mainly taken in a direct trawl fishery in deep water near the Northern Shelf edge and the Norwegian deeps. Norwegian, French, and German trawlers take the majority of the catches. In the first half of the year the fishery is directed towards mature fish, while immature fish dominate in the catches the rest of the year. The main fishery was developed in the beginning of 1970s. In later years, the trawlers have also exploited deep-water fish.

The fishery in Subarea VI consists largely of a directed French, German, and Norwegian deep-water fishery operating on the shelf edge, and a Scottish fishery operating inshore.

The proportional contribution of saithe landings by area over different periods is as follows:

| Period | Area IIIa \& IV | Area VI |
| :---: | :---: | :---: |
| $1982-1998$ | $86 \%$ | $14 \%$ |
| $1988-1998$ | $87 \%$ | $13 \%$ |
| $1993-1998$ | $91 \%$ | $9 \%$ |

The assessment of saithe in the North Sea and area VIa was reviewed by the North Sea Commission Fisheries Partnership in August 2002. The review consisted of a scientific review by three independent scientific experts and a public review with the participation of fishermen organizations. The general conclusion of the review was that the assessment was carried out according to appropriate standards although there was concern about the reliance on commercial CPUE data for the calibration of the assessment. The fishermen broadly shared the perception on the development in the stock.

Analytical assessment is based on catch-at-age analysis using CPUE information from commercial fisheries. Lack of recruitment indices for recent and incoming year classes makes catch predictions imprecise.

Source of information: Report of the Working Group on the Assessment of Demersal Stocks in the North Sea and Skagerrak, 11 - 20 June 2002 (ICES CM 2003/ACFM: 02 ).

${ }^{*}$ GM mean

State of stock/exploitation: The stock is outside safe biological limits. SSB in 2002 is below $\mathbf{B}_{\mathrm{pa}}$ and fishing mortality in 2001 was above $\mathbf{F}_{\mathrm{pa}}$. Spawning stock biomass has declined from 1989 to 1997, where it reached its historical minimum, but has increased in recent years due to the strong 1996 year class. Fishing mortality increased from the 1960 s to the 1990s, reaching a record high in 1997 and has declined since then. Except for the 1996 year class, recruitment since 1993 has been below average. Surveys indicate that the 2001 year class is strong.

Management objectives: In 1999, the EU and Norway have "agreed to implement a long-term management plan for the plaice stock, which is consistent with the precautionary approach and is intended to constrain harvesting within safe biological limits and designed to provide for sustainable fisheries and greater potential yield. The plan shall consist of the following elements:

1. Every effort shall be made to maintain a minimum level of SSB greater than $210000 t\left(\boldsymbol{B}_{\text {lim }}\right)$.
2. For 2000 and subsequent years the Parties agreed to restrict their fishing on the basis of a TAC consistent with a fishing mortality of 0.3 for appropriate age groups as defined by ICES.
3. Should the SSB fall below a reference point of $300000 t\left(\boldsymbol{B}_{p a}\right)$, the fishing mortality referred to under paragraph 2 shall be adapted in the light of scientific estimates of the conditions then prevailing. Such adaptation shall ensure a safe and rapid recovery of SSB to a level in excess of $300000 t$.
4. In order to reduce discarding and to enhance the spawning biomass of plaice, the Parties agreed that the exploitation pattern shall, while recalling that other demersal species are harvested in these fisheries, be improved in the light of new scientific advice from, inter alia, ICES.

The Parties shall, as appropriate, review and revise these management measures and strategies on the basis of any new advice provided by ICES."

ICES considers that the agreed Precautionary Approach reference points in the management plan are consistent with the precautionary approach, provided they are used as upper bounds on F and lower bounds on SSB, and not as targets.

Precautionary approach reference points (unchanged since 1998):

| ICES considers that: | ICES proposes that: |
| :--- | :--- |
| $\mathbf{B}_{\text {lim }}$ is 210000 t , the lowest observed biomass. | $\mathbf{B}_{\mathrm{pa}}$ be set at 300000 t . This is the previously agreed <br> MBAL and affords a high probability of maintaining SSB <br> above $\mathbf{B}_{\text {lim }}$, taking into account the uncertainty of <br> assessments. |
| $\mathbf{F}_{\text {lim }}$ is 0.6. | $\mathbf{F}_{\mathrm{pa}}$ be set at 0.30. This F is considered to provide <br> approximately 95\% probability of avoiding $\mathbf{F}_{\text {lim }}$, taking <br> into account the uncertainty of the assessment. |

## Technical basis:

| $\mathbf{B}_{\text {lim }}=\mathbf{B}_{\text {loss }}=210000 \mathrm{t}$. | $\mathbf{B}_{\mathrm{pa}}$ Approximately $1.4 \mathbf{B}_{\text {lim }}$, previous MBAL. |
| :--- | :--- |
| $\mathbf{F}_{\text {lim }}=\mathbf{F}_{\text {loss }}=0.6$. | $\mathbf{F}_{\mathrm{pa}}=55^{\text {th }} \%$ of $\mathbf{F}_{\text {loss }}(0.6)$ is 0.36, which implies that $\mathbf{B}_{\text {eq }}<$ <br>  <br>  <br>  <br>  <br>  <br> $\mathbf{B}_{\mathrm{pa}}$. <br> $\mathbf{B}_{\text {eq }}>\mathbf{B}_{\mathrm{pa}}$ and a less than $10 \%$ probability that $\mathbf{S S B}_{\mathrm{MT}}<$ <br> $\mathbf{B}_{\mathrm{pa}}$. |

NB: As F increases above 0.3, $\mathrm{P}\left(\mathbf{S S B}_{\mathrm{MT}}<\mathbf{B}_{\mathrm{pa}}\right)$ increases rapidly.

Advice on management: ICES recommends that the fishing mortality be less than $\mathrm{F}=0.23$ in order to bring SSB above $B_{p a}$ in 2004. This corresponds to landings of less than $\mathbf{6 0 0 0 0} \mathbf{t}$ in 2003. This implies a reduction in fishing mortality of at least $40 \%$. Management of fisheries taking plaice must respect the stringent restrictions on the catch and discard rates advised for cod, with effective monitoring of compliance with those restrictions.

Relevant factors to be considered in management: Although there is some by-catch of cod in the plaice fisheries the impact of the agreed technical measures as outlined in EU regulations 850/98 and 2056/2001, and UK measures SSI 227/2000, SSI 250/2001 and SI 649/2001 that will be implemented from 2002 onwards are not likely to impact the plaice fishery and stock substantially.

The assessment is considered to be uncertain. One major source of uncertainty is the absence of discard data from the analysis when discarding is high and increasing. The surveys used for calibrating the assessment may only cover part of the stock. There are conflicting signals about the trends in the stock from the fishermen and from the assessment.

There is evidence from the surveys, sampling, and assessment that the strong 1996 year class suffered extensive discarding and a substantial portion of its potential contribution to yields and SSB was wasted. With the 2001 year class appearing strong at this time, extra measures to reduce captures prior to attaining marketable size would be appropriate and beneficial to development of fisheries and SSB in the next few years.

## Catch forecast for 2003:

Basis: $\mathrm{F}(2002)=\mathbf{F}_{\mathrm{sq}}=\mathrm{F}(99-01)$ scaled $=0.38$; Landings $(2002)=97 ; \operatorname{SSB}(2003)=269$.

| $\mathrm{F}(2003$ onwards | Basis | Landings <br> $(2003)$ | SSB (2004) |

| 0.34 | $0.9 * \mathbf{F}_{\mathrm{sq}}$ | 85.6 | 276 |
| 0.38 | $1.0 * \mathbf{F}_{\mathrm{sq}}$ | 93.4 | 269 |

Weights in '000 t.
Shaded scenarios considered inconsistent with the precautionary approach.

Comparison with previous assessments: Contrary to previous assessments the current retrospective analysis does not show a retrospective bias of consistent overestimation of SSB. The current assessment is generally consistent with last year's assessment, although the 2001 data on age compositions has introduced a revision in the perception of both fishing mortality and SSB.

Elaboration and special comment: North Sea plaice is taken mainly in a mixed flatfish fishery by beam trawlers in the southern and southeastern North Sea. Directed fisheries are also carried out with seine and gillnet, and by beam trawlers in the central North Sea.

Since 1989, an area with high concentrations of small plaice ("Plaice Box") was closed to beam trawl fisheries with vessels $>300 \mathrm{hp}$ during the second and third quarter and, since 1994, during the fourth quarter as well. Since 1995, the plaice box has been closed for the whole year. Beam trawlers $<300 \mathrm{hp}$ are allowed to fish inside the box. Effort reductions have mainly been effective since 1994 when the fourth quarter was closed and when effort levels in the box decreased to around $10 \%$ of the pre-box level.

Due to the minimum mesh size ( 80 mm ) in the mixed beam trawl fishery, south of $55^{\circ} \mathrm{N}$, or $56^{\circ} \mathrm{N}$ east of $5^{\circ} \mathrm{E}$, large numbers of (undersized) plaice are discarded. The 80 mm mesh size is obviously not matched to the minimum landing size of plaice. Estimates of discards are not included in the assessment since time-series of
discards are not available. Ongoing sampling programmes indicate that discarding in recent years has increased from about $50 \%$ in numbers historically to 70 $80 \%$ in 2000 and 2001. The high estimates of discards in recent years may be caused by a reduction in growth, which extends the time the fish is undersized and subject to discarding. There is a need for continuous monitoring of discards and special attention should be given to reconstructing recent discard trends so as to improve the assessment of this stock.

The stock-recruitment plot suggests that in recent years recruitment has declined at lower SSB. However, recruitment surveys at age zero do not indicate such a reduction, and it is possible that the lower estimated recruitment in the assessment may be explained by an increase in discarding.

The North Sea Commission Fisheries Partnership reviewed the assessment for North Sea plaice in August 2002. The review consisted of a scientific review by three independent scientific experts and a public review with the participation of fishermen organizations. The general conclusion of the scientific review was that the assessment was carried out according to appropriate standards although it was acknowledged that the assessment was uncertain. The fishermen expressed a different perception on the development in the stock compared to the stock assessment.

Preliminary simulations have been carried out to evaluate the potential effects of the technical
interactions between fleets harvesting plaice and sole. Although the linkage between plaice and sole has not quantified, the results indicate that the required reduction in fishing mortality for plaice and sole based on single species considerations may be incompatible.

Multiannual TAC Arrangements and Recovery Plans: Section 3.5.17 reviewed a study on schemes for Multiannual advice on TACs for four plaice and two sole stocks. These studies indicated possible target fishing mortalities for specific TAC schemes. ICES considers that target values must be defined by management taking scientific studies into account. ICES has not received feed-back with specification of target reference points and therefore continues to provide advice based on the precautionary reference points consistent with previous practice.

Analytical assessment uses data from two research surveys for calibration. Forecasts use survey indices up to and including 2002. No discard datas are used in the assessment.

### 3.5.7 Sole in Subarea IV (North Sea)

State of stock/exploitation: The stock is outside safe biological limits. SSB in 2002 is below the proposed $\mathbf{B}_{\mathrm{pa}}$, and fishing mortality in 2001 remains above $\mathbf{F}_{\mathrm{pa}}$. The spawning stock reached an historic low in 1998 below $\mathbf{B}_{\text {lim }}$. It increased sharply following recruitment of the
strong 1996 year class. The 2001 year class is above average.

Management objectives: No explicit management objectives are set for this stock.

Precautionary Approach reference points (unchanged since 1999):

| ICES considers that: | ICES proposes that: |
| :--- | :--- |
| $\mathbf{B}_{\text {lim }}$ is $25000 t$, the lowest observed biomass. | $\mathbf{B}_{\text {pa }}$ be set at 35000 t . This affords a high probability of <br> maintaining SSB above $\mathbf{B}_{\text {lim }}$, taking into account the <br> uncertainty of assessments. |
| $\mathbf{F}_{\text {lim }}$ is undefined. | $\mathbf{F}_{\mathrm{pa}}$ be set at 0.4. This F is considered to provide a greater <br> than $95 \%$ probability of avoiding $\mathbf{B}_{\text {lim }}$, taking into <br> account the uncertainty of the assessment. |

Technical basis:

| $\mathbf{B}_{\text {lim }}=\mathbf{B}_{\text {loss }}=25000 \mathrm{t}$. | $\mathbf{B}_{\mathrm{pa}}=1.4 * \mathbf{B}_{\text {lim }}$. |
| :--- | :--- |
|  | $\mathbf{F}_{\mathrm{pa}}=5^{\text {th }}$ percentile $(0.49)$ of $\mathbf{F}_{\text {loss }}$ implies $\mathrm{B}_{\text {eq }}<\sim \mathbf{B}_{\mathrm{pa}}, \mathrm{F}=$ |
|  | 0.4 implies $\mathbf{B}_{\mathrm{eq}}>\mathbf{B}_{\mathrm{pa}}$ and $\mathrm{P}\left(\mathbf{S S B} \mathbf{B}_{\mathrm{MT}}<\mathbf{B}_{\mathrm{pa}}\right)<10 \%$. |

Advice on management: ICES recommends that the fishing mortality be less than $F_{p a}=0.4$, corresponding to landings of less than $14600 t$ in 2003. This implies a reduction in fishing mortality of at least $23 \%$. Management of fisheries taking sole must respect the stringent restrictions on the catch and discard rates advised for cod, with effective monitoring of compliance with those restrictions.

Relevant factors to be considered in management: The peaks in SSB of this stock are heavily dependent on the occasional occurrence of strong year classes. The SSB and landings in recent years have been dominated by the abundant 1996 year class. The stock is expected to decrease in 2003 just above $\mathbf{B}_{\text {lim }}$, but well below $\mathbf{B}_{\mathrm{pa}}$. However, because of a strong 2001 year class, the stock is expected to increase above $\mathbf{B}_{\mathrm{pa}}$ in 2004. TACs in recent years have been agreed above the recommended $\mathrm{F}_{\mathrm{pa}}$.

Sole is mainly caught in a mixed beam trawl fishery with plaice using 80 mm mesh in the southern North Sea. This means it is important to take into account the impact of management measures for plaice when considering sole. There is not a simple one-to-one link between the catch of sole and plaice when considering
effort reduction. The proposed reduction in fishing mortality for plaice is $40 \%$, while the advice given for sole implies a reduction of at least $23 \%$.

Management measures, which result in a reduction in the mortality on juvenile sole would benefit the stock. The continued use of 80 mm mesh together with the minimum landing size of 24 cm results in a high proportion of sole being landed which are immature.

The impact of the agreed technical measures that will be implemented from 2002 onwards are not likely to impact the sole stock. Technical measures introduced in January 2000 have extended the area where fishing with 80 mm is allowed from $55^{\circ} \mathrm{N}$ to $56^{\circ} \mathrm{N}$ east of $5^{\circ} \mathrm{E}$. ICES is not able to assess the impact of this measure, but it is considered unlikely to have a substantial impact on the sole stock as long as it represents the northern limit of the distribution of sole.

The by-catch and discard limits advised for cod and other management measures that may be implemented to promote the recovery of cod need to be respected in the prosecution of the mixed plaice-sole fisheries. By-catch or discards should be quantified.

Catch forecast for 2003:
Basis: $\mathrm{F}(2002)=\mathbf{F}_{\mathrm{sq}}=\mathrm{F}(1999-2001$, scaled $)=0.52$; Landings $(2002)=16.8 ; \mathrm{SSB}(2003)=25.7$.

Weights in ' 000 t .
Shaded scenarios considered inconsistent with the precautionary approach.

Medium- and long-term projections: Medium-term analyses (Figures 3.5.7.1 and 3.5.7.2) indicate that yield and SSB are expected to decrease at the current fishing mortality ( $\mathrm{F}=0.52$ ). SSB will fall below $\mathbf{B}_{\mathrm{pa}}$. Fishing at $\mathbf{F}_{\mathrm{pa}}$ is expected to give a high probability of SSB being above $\mathbf{B}_{\mathrm{pa}}$.

## Comparison with previous assessment and advice:

 The main change in the assessment compared with last year is a change in the calibration data used for the assessment and a revision of the catch data. The stock is now assessed to be outside safe biological limits.Elaboration and special comment: Sole is mainly taken by beam trawl fleets in a mixed fishery for sole and plaice in the southern part of the North Sea. The minimum mesh size permitted when fishing for sole is 80 mm . Beam trawl fleets started to develop in the mid1960s, and have expanded up to the 1990s. A relatively small part of the catch is taken in a directed fishery by gillnetters in coastal areas, mostly in the $2^{\text {nd }}$ quarter of the year. Since 1989, the distribution pattern of the beam trawl fleets $>300 \mathrm{HP}$ has changed due to the introduction of the 'Plaice Box' in the southeastern part of the North Sea.

A knife-edged maturity ogive is used for sole, implying maturity at age 3 . There is evidence from previous working documents that this may substantially overestimate the proportion of mature sole in some years.

Preliminary simulations have been carried out to evaluate the potential effects of the technical interactions between fleets harvesting plaice and sole. Although the linkage between plaice and sole has not quantified, the results indicate that the required
reduction in fishing mortality for plaice and sole based on single species considerations may be incompatible.

Analytical assessment (XSA) uses data from two research surveys and two commercial CPUE series for calibration. Forecasts use survey indices up to and including 2002. No discard data are used in the assessment.

Multiannual TAC Arrangements and Recovery Plans: Section 3.5.17 reviewed a study on schemes for Multiannual advice on TACs for four plaice and two sole stocks. These studies indicated possible target fishing mortalities for specific TAC schemes. ICES considers that target values must be defined by management taking scientific studies into account. ICES has not received feed-back with specification of target reference points and therefore continues to provide advice based on the precautionary reference points consistent with previous practice.

Source of information: Report of the Working Group on the Assessment of Demersal Stocks in the North Sea and Skagerrak, 11 - 20 June 2002 (ICES CM 2003/ACFM: 02 ).

Figure 3.5.7.1

Figure 3.5.7.2

State of stock/exploitation: The stock is inside safe biological limits. SSB in 2001 was estimated at 1.4 million t and is expected to increase to 1.7 million tons in 2002, which is above the $\mathbf{B}_{\mathrm{pa}}$ of 1.3 million t . SSB has increased gradually since the low stock size in the mid 1990s. This in response to reduced catches, strong recruitment and management measures that reduced exploitation both on juveniles and adults. In 1996 the fishing mortality for the adult part of the stock was reduced to 0.43 . It has further decreased in subsequent years, being 0.24 in 2001. For juveniles the fishing mortality remained below 0.1 since 1996. Both, the 1998 year class and the 2000 year class appear to be very strong in all the surveys.

Management objectives: According to the EU-Norway agreement (December 1997):

1. Every effort shall be made to maintain a level of Spawning Stock Biomass (SSB) greater than the Minimum Biological Acceptable level (MBAL) of 800.000 tonnes.
2. A medium-term management strategy, by which annual quotas shall be set for the directed fishery and for by-catches in other fisheries as defined by ICES, reflecting a fishing mortality rate of 0.25 for 2-ringers and older and 0.12 for $0-1$-ringers, shall be implemented.
3. Should the SSB fall below a reference point of 1.3 million tonnes, the fishing mortality rates referred to under paragraph 2, will be adapted in the light of scientific estimates of precise conditions then
4. prevailing, to ensure rapid recovery of SSB to levels in excess of 1.3 million tonnes.

The recovery plan referred to above may, inter alia, include additional limitations on effort in the form of special licensing of vessels, restrictions on fishing days, closing of areas and/or seasons, special reporting requirements or appropriate control measures.
5. By-catches of herring may only be landed in ports where adequate sampling schemes to effectively monitor the landings have been set up. All catches landed shall be deducted from the respective quotas set, and the fisheries shall be stopped immediately in the event that the quotas are exhausted.
6. The allocation of the TAC for the directed fishery for herring shall be $29 \%$ to Norway and $71 \%$ to the Community. The by-catch quota for herring shall be allocated to the Community.
7. The Parties shall, if appropriate, consult and adjust management measures and strategies on the basis of any new advice provided by ICES including that from the assessment of the abundance of the most recent year class.
8. A review of this agreement shall take place no later than 31 December 2001.
9. This agreement shall enter into force on 1 January 1998.

ICES considers the agreement to be consistent with the precautionary approach.

Precautionary Approach reference points (unchanged since 1999):

| ICES considers that: | ICES proposed that: |
| :--- | :--- |
| $\mathbf{B}_{\text {lim }}$ is 800000 t | $\mathbf{B}_{\mathrm{pa}}$ be set at 1.3 mill t |
| $\mathbf{F}_{\text {lim }}$ is not defined | $\mathbf{F}_{\mathrm{pa}}$ be set at $\mathbf{F}_{\text {ages 0-1 }}=0.12 ;$ at $\mathbf{F}_{\text {ages 2-6 }}=0.25$ |

## Technical basis:

| $\mathbf{B}_{\text {lim }}:$ below this value poor recruitment has been <br> experienced | $\mathbf{B}_{\mathrm{pa}}$ : part of a harvest control rule based on simulations |
| :--- | :--- |
| $\mathbf{F}_{\text {lim }}$ : Not defined | $\mathbf{F}_{\mathrm{pa}}:$ part of a harvest control rule based on simulations |

Advice on management: ICES advises that catches in 2003 should be within the constraints on fishing mortality agreed by EC and Norway, i.e. less than $\mathrm{F}_{2-6}$ $=0.25$ and $F_{0-1}=0.12$. Several such options are presented in the Management Option table. The fisheries on herring in Division IIIa should be managed in accordance with the management advice given on spring-spawning herring in Section 3.4.7.

Analyses of survey data suggest that the catches in 2003 in Divisions IVc and VIId (Downs herring) should not exceed the TAC for 2002.

Relevant factors to be considered in management: Catches on adult herring in recent years have consistently exceeded the agreed TAC, mainly due to misreporting
from other ICES areas into and out of the North Sea; this gives rise to overshooting of the TAC.

The 1998 year class is strong and comprises almost $45 \%$ of SSB in 2002. In the past large year classes have tended to have a lower maturation rate than the long-term average. So far these signals have not been detected for the 1998 yearclass, as the proportion, which mature, appears to be above average.

The ICES advice is based on the projected SSB in 2003 being above 1.3 million t . SSB in 2003 depends on the fisheries in 2002 and that part in 2003 that takes place before spawning. About $2 / 3$ of the total mortality is expected to be realised before spawning each year. The increase in SSB expected in 2003 depends strongly on the incoming 1998 and 2000 year classes. Observations from different surveys indicate that these year classes are strong. Although the 1998 year class and the 2000 year class appear to be very strong in all the surveys, they have not been well represented in the catches. The reason for this discrepancy is not clear at present. Generally, the surveys provide more reliable indications of year class strength than catches of juveniles do.

Catch Forecast for 2003: Catch options are given for 2003, for limits on the fishing mortality rate, which reflect both the ICES recommendation and the EUNorway agreement. Catch forecasts assume $\mathbf{F}$ status quo for all fleets for $2002\left(=\mathbf{F}_{2001}\right)$, because the alternative
assumption of a catch constraint produced an unrealistic decrease in F . This implies $\mathbf{F}$ on adults close to 0.25 , but a low fishing mortality on juveniles.

There are many possible permutations of catches by the four fleets that could result in the desired values of $\mathbf{F}_{0}$ ${ }_{1}$ and $\mathbf{F}_{2-6}$. Hence, there is some liberty within the framework set by the fishing mortalities for managers to decide the proportion of the total catch to be allocated to each of the fleets. The following options are provided:

Two options are included where the fishing mortality of the C and D fleets varies in proportion with the B fleet, maintaining the ratios between these fleets as in the status quo fishing mortalities. The examples have $\mathbf{F}_{2-6}$ close to 0.2 , but different fishing mortalities for the $0-1$ ringers.

In the remaining options, some combinations of fishing mortalities for the four fleets that give an $\mathbf{F}_{0-1}$ close to 0.12 and $\mathbf{F}_{2-6}$ close to 0.25 are shown. The combinations in addition satisfy constrains that the catch by the C fleet shall be close to either 30,50 or 70 thousand tonnes, and the catch of the D fleet close to either 10,20 or 30 thousand tonnes.

All scenarios indicate a rapid increase in spawning biomass and in yield. This is mainly caused by the 1998 year class, which is estimated to be strong, and the 2000 year class, which also appears strong in the surveys.

Catch Forecast for 2003

| Assuming $F$ status quo in 2002 |  |  |  |  |  |  |  |  |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| $\mathrm{F}_{2-6}$ | $\mathrm{F}_{0-1}$ | $\mathrm{F}_{0-1}$ | $\mathrm{F}_{0-1}$ | $\mathrm{F}_{0-1}$ | $\mathrm{F}_{2-6}$ | Yield 2002 |  |  |  |  |  | SSB |
| A | B | C | D |  |  | A | B | C | D | B-D | Total | 2002 |
| 0.226 | 0.01 | 0.017 | 0.014 | 0.043 | 0.243 | 403 | 16 | 52 | 12 | 80 | 483 | 1699 |

## Fleet definitions:

A: Directed herring fisheries with purse seiners and trawlers in the North Sea;

B: All other vessels, which take herring as bycatch in the North Sea;

C: Directed fisheries with purse seiners and trawlers in Division IIIa;

D: Vessels fishing in Division IIIa for herring and sprat and other vessels participating in fisheries where herring is taken as by-catch in Division IIIa.

The following bullet points apply for all options presented above:

- $\quad \mathbf{F}_{2-6}$ is the total F averaged over 2-6-ringers;
- $\quad \mathbf{F}_{0-1}$ is the total F averaged over 0-1-ringers;

Medium- and long-term projections: The mediumterm projections are heavily dependent on the stockrecruitment relationship. The currently estimated parameters for the Beverton and Holt stock-recruitment tend to give very optimistic trends in SSB at the current levels of SSB. Medium-term projections are available in the HAWG report, but because of the above concerns are not regarded as useful for management consideration. Medium-term forecasts indicate that a fishing mortality of 0.25 on adult herring, and 0.12 on juvenile herring, will give a high probability of SSB being above $\mathbf{B}_{\mathrm{pa}}$.

## Comparison with previous assessment and advice:

 As noted above, assessments of this stock show a tendency to overestimate stock size and underestimate fishing mortality. Compared with the 2001 assessment, the 2002 assessment increased the influence of the more precise surveys on results and decreased the influence of juvenile catch. The result of these revised assessment methods is a $22 \%$ greater estimate of the 2000 stock size and a lower estimate of the fishing mortality than in the 2001 assessment. Nevertheless, both methods have internal inconsistencies that tend to overestimate stock size.Elaboration and special comment: Stock depletion in the 1970s resulted in a four-year closure of the directed fishery. The stock recovered during the 1980s. Following the re-opening of the fishery, the fishing mortality rate steadily increased. By the 1990s this rate was no longer sustainable and the SSB fell below the MBAL of 800000 t . Emergency regulations were introduced to reduce TACs which reduced the fishing mortality rate substantially.

The directed fisheries (fleet A in the North Sea and fleet C in the Skagerrak/Kattegat area) have been managed by TACs since the re-opening of the North Sea herring fisheries in 1981. Fleet D, landing herring as by-catch, has also previously been managed by TAC for mixed clupeoids. It has been managed by a by-catch ceiling since 1996. The catch of fleet A has been higher than the agreed TAC and in 2001 was about $16 \%$ above the agreed TAC of 265000 t . The by-catch of herring in the small mesh fishery has been low since 1997.

The total catch of North Sea autumn-spawners, taken in all areas in 2001, comprises around $60 \%$ immature fish (in numbers), which is more than in recent years, but significantly lower than the $80 \%$ in 1995 and earlier years.

The harvest control rule, which forms the basis for advice, separates the mortality for adults and juveniles. Fleet A catches adults, fleets B and D catch juveniles, and fleet C catches both. Therefore, the harvest control rule does not determine the catches uniquely, but offers some flexibility to the share of the catch between the fleets.

To obtain catch forecasts, projections by fleet are performed for the whole area. The area split that was used in previous years was shown to add little to the predictive power of the process.

This stock complex also includes Downs herring (herring in Divisions IVc and VIId), which has shown independent trends in exploitation rate and recruitment, but cannot be assessed separately. Abundance indices from larvae and trawl surveys indicate that since 1995 the SSB of the Downs herring has increased. The Downs fishery is concentrated on the spawning aggregations in a restricted area, which makes this stock component particularly vulnerable to excessive fishing pressure. EU splits its share of the total TAC (Subarea IV and Division VIId) into TACs for Divisions $\mathrm{IVa}+\mathrm{IVb}$ and for Divisions IVc+VIId. In response to ICES advice in May 1996 the IVc+VIId TAC was reduced by $50 \%$ in line with reductions for the whole North Sea. The TAC for Downs herring was reduced from 50000 t to 25000 t and has remained there until 2001. TACs for this component have been significantly exceeded in all years. The TAC for this component was increased in 2002 (to $42,000 \mathrm{t}$ ) following the advice of ICES in 2001. However, the strong increase in SSB in the North Sea stock in 2001 is not mirrored in the Downs component, and therefore the TAC for Downs herring should not increase.

Catches for recent years from Divisions IVc and VIId are found in Table 3.5.8.5.

Age-based assessment is based on landings of North Sea Autumn Spawning herring in Subarea IV, Divisions VIId and IIIa and surveys. Incomplete discard data are available.

Source of information: Report of the Herring Assessment Working Group for the Area South of $62^{\circ} \mathrm{N}$, March 2002 (ICES CM 2002/ACFM:12).

${ }^{1}$ Includes catches in directed fishery and catches of 1ringers in small mesh fishery up to 1992.
${ }^{2}$ IVa,b and EC zone of IIa.
${ }^{3}$ Provided by Working Group members.
${ }^{4}$ One country only.
${ }^{5}$ Includes spring spawners not included in assessment.
${ }^{6}$ Revised during 1991.
${ }^{7}$ Based on $\mathbf{F}=0.3$ in directed fishery only; TAC advised for IVc, VIId subtracted.
${ }^{8}$ Estimated.
${ }^{9}$ 130-180 for spring spawners in all areas.
${ }^{10}$ Based on sum-of-products (number x mean weight at age).
${ }^{11}$ Status quo $\mathbf{F}$ catch for fleet A.
${ }^{12}$ The catch should not exceed recent catch levels.
${ }^{13}$ During the middle of 1996 revised to $50 \%$ of its original agreed TAC.
${ }^{14}$ Included in IVa, b.
${ }^{15}$ Managed in accordance with autumn spawners.
${ }^{16}$ Figure altered in 2000.
${ }^{17}$ Figure altered in 2001.
${ }^{18}$ Data for 1995 show some inconsistencies and need to be revised intersessionally
${ }^{19}$ Fleet D and E are merged from 1999 onwards.

### 3.5.9 Sprat in the North Sea (Subarea IV)

State of stock/exploitation: The sprat stock shows signs of being in good condition, as the biomass seems to be stable and relatively high. There is an indication from the IBTS (February) 2002 survey of a good 2001 year class recruiting to the 2002 fishery (the age-1 index in 2002 was among the highest observed).

Management objectives: There are no explicit management objectives for this stock.

Advice on management: For this stock only in-year advice is available. Based on the historic relationship between survey and catch, the 2002 survey value indicates that a catch of 160000 t in 2002 would allow SSB to remain stable or increase.

Relevant factors to be considered in management: Sprat has a short life span, and most of the production of the stock is therefore likely to be due to recruitment and the growth of recruits rather than the growth of postrecruits. The use of the IBTS (February) as an index of abundance may introduce some underestimation of the stock biomass, because the surveys cannot cover the most shallow parts of the North Sea where sprat also occur.

The proportion of herring by-catch in the sprat fishery has been around $8 \%$ for the last four years. In 2002, high by-catch of 0 - and 1 -ringer herring is expected to occur during the third and the fourth quarter as the incoming year classes of herring are estimated to be strong.

Therefore, the sprat fishery in 2002 may be restricted by the existing limit placed on the allowable by-catch of herring, rather than by the actual sprat TAC.

Catch forecast for 2003: Because the fishery in a given year is very dependent on that year's incoming year class of sprat, ICES is not able to predict catches for 2003.

Comparison with previous assessment and advice: The assessment method and input data were similar to last year. The decrease in the advised TAC (160 000 t compared to 225000 t advised last year) reflects changes in the stock.

Elaboration and special comment: The present assessment and TAC-setting regime requires a two-year forecast. This means that the estimated TAC for 2003 has to be calculated in 2002 based on data collected in 2001. This may not be a realistic approach for a stock consisting of only a few year classes, with a predominance of 1 -year-old fish in the catches. Instead, a two-step management process is suggested consisting of a provisional TAC for January-March 2003 that could be revised in April, taking into account the most recent survey data. Although this would require a change in the actual process of setting TACs for sprat, it would result in a better utilisation of this stock.

Source of information: Report of the Herring Assessment Working Group for the Area South of $62^{\circ} \mathrm{N}$, March 2002 (ICES CM 2002/ACFM:12).

IBTS Index and Catch

Figure 3.5.9.1 IBTS Sprat Index (February) and catch of the entire year.

### 3.5.10 Mackerel in Subarea IV (North Sea component)

For information on this mackerel component see mackerel (combined Southern, Western and North Sea spawning components) section 3.12.3.

### 3.5.11 North Sea horse mackerel (Trachurus trachurus) (Division IIIa (eastern part), Divisions IVb,c, VIId)

State of stock/exploitation: The state of the stock is not known. There is no recent quantitative information on stock size. Catches have been increasing in recent years.

Management objectives: No explicit management objectives have been established for this stock.

Precautionary Approach Reference points: No precautionary reference points have been proposed for this stock.

Advice on management: ICES recommends that catches in 2003 be no more than the 1982-1997 average of 18000 t , in order to avoid an expansion of the fishery until there is more information about the structure of horse mackerel stocks, and sufficient information to facilitate an adequate assessment.

Relevant factors to be considered in management: Advice in 1999 was to constrain expansion of the fishery until there was a scientific basis for advice because high catch rates can be maintained in pelagic fisheries even when the stock is in decline. Despite this advice catches increased by one third, from about 37000 t in 1999 to 48000 t in 2000 and 46000 t in 2001. ICES maintains this advice reflecting its concern over the potential impact of the recent expansion of the fishery.

These fish migrate out of the North Sea to areas where they mix with the western horse mackerel stock. The present agreed TAC is for the North Sea and Division IIa and this area does not correspond to the distribution area of the stock. The TAC should apply to all those areas where the North Sea horse mackerel are fished, i.e. Divisions IIIa, IVb,c and VIId.

In recent years there has been a change in the age composition of the landings with a higher proportion of
younger age groups. In 1998 about 55\%, in 1999 40\%, and in $200174 \%$ of the catch in numbers were fish 1-4 years old. The 1998 year class appears to be abundant in the landings in recent years and may be a relatively strong year class.

Catch forecast for 2003: Not available.

Medium- and long-term projections: Not available.

Elaboration and special comment: The stock cannot be assessed unless adequate data become available. Egg surveys from 1989 to 1991 indicated a spawning stock biomass of about 240000 t . The age composition of the relatively small catches until 1997 and the past biomass estimates suggest that the exploitation rate may have been low in the early 1990s. However, the catch increased from a long-term level of 18000 t to the historic high in 2000 of 48000 t , and was close to that level in 2001. The exploitation in recent years may therefore have been increasing.

In earlier years the majority of the catch was taken as by-catch in the small-mesh industrial fishery. In recent years most of the catch has come from a directed fishery for human consumption, mainly in Division VIId.

The allocation of catches to the different horse mackerel stocks is based on the temporal and spatial distribution of the fishery. It is therefore important that the fishing nations report their catches by ICES rectangle and by quarter.

Source of information: Report of the Working Group on the Assessment of Mackerel, Horse Mackerel, Sardine and Anchovy, 10 - 19 September 2002 (ICES CM 2003/ACFM:07).

### 3.5.12 Norway pout in ICES Subarea IV and Division IIIa

State of stock/exploitation: The stock is within safe biological limits. Recruitment is highly variable and influences stock size rapidly due to the short life span of the species. Fishing mortality has generally been lower than the natural mortality and fishing mortality has generally decreased in recent years to well below the long-term average.

Management objectives: There is no management objective set for this stock. With present fishing mortality levels the state of the stock is more determined by natural processes and less by the fishery. However, there is a need to ensure that the stock remains high enough to provide food for a variety of predator species.

Precautionary Approach reference points (Unchanged since 1997):

| ICES considers that: | ICES proposes that: |
| :--- | :--- |
| $\mathbf{B}_{\text {lim }}$ is 90000 t , the lowest observed biomass. | $\mathbf{B}_{\mathrm{pa}}$ be established at 150000 t. This affords a high <br> probability of maintaining SSB above $\mathbf{B}_{\text {lim }}$, taking into <br> account the uncertainty of assessments. Below this <br> value the probability of below-average recruitment <br> increases. |

Note: With present fishing mortality levels the status of the stock is more determined by natural processes and less by the fishery. It may be more appropriate to formulate reference points based on total mortality, recruitment, and stock biomass for use within management procedures using surveys (and real-time monitoring of catches). However, it is a question whether the 0 -group is fully recruited to the $3^{\text {rd }}$ quarter surveys in relation to forecast based on surveys alone. Forecast of the 0 -group is relevant as the fishery starts on the 0 -group already in $3^{\text {rd }}$ and $4^{\text {th }}$ quarter of the year.

Technical basis:

| $\mathbf{B}_{\text {lim }}=\mathbf{B}_{\text {loss }}=90000 \mathrm{t}$. | $\mathbf{B}_{\mathrm{pa}}$ Below-average recruitment below: 150000 t. |
| :--- | :--- |
| $\mathbf{F}_{\text {lim }}$ None advised. | $\mathbf{F}_{\mathrm{pa}}$ None advised. |

## Advice on management: The stock can sustain current fishing mortality.

## Relevant factors to be considered in management:

 The stock can on average sustain current fishing mortality. The fishery targets both Norway pout and blue whiting. In managing this fishery, by-catches of haddock, whiting, and blue whiting should be taken into account and existing measures to protect these by-catch species should be maintained.This stock is an important food source for other species The fishing mortality is lower than the natural mortality, and multispecies analyses have indicated that when F is below $M$ for these types of species, the fisheries are not causing problems for their predators on the scale of the stock. Locally concentrated harvesting may cause local and temporary depletions of food for predators and, therefore, harvesting should be spread widely across the stock area. The population dynamics of Norway pout in the North Sea and Skagerrak are very dependent on changes caused by recruitment variation and predation mortality (or other natural mortality causes) and less by the fishery.

Deterministic catch forecasts are not feasible because: (a) the potential catches are largely dependent on the size of a few year classes, (b) large dependence on the strength of the recruiting 0 -group year classes that is unknown for

2002, and (c) added uncertainty arising from variations in natural mortality.

Comparison with previous assessment and advice: The assessment and advice is largely consistent with those from previous years. SSB in 2001 has been revised upwards by $5 \%$ and fishing mortality in 2000 was revised downwards by $13 \%$.

Catch forecast for 2003: Deterministic catch forecasts are not feasible for this stock.

Medium- and long-term projections: No medium-term predictions are carried out for this stock.

Elaboration and special comment: The fishery is mainly by Danish and Norwegian vessels using small mesh trawls in the northern North Sea at Fladen Ground and along the edge of the Norwegian Trench. Main fishing seasons are $1^{\text {st }}, 3^{\text {rd }}$, and $4^{\text {th }}$ quarters of the year. The fishery targets both Norway pout and blue whiting. The assessment is analytical using catch-at-age analysis based on quarterly catch and CPUE data. The assessment is considered appropriate to indicate trends in the stock and immediate changes in the stock because of the seasonal assessment taking into account the seasonality in fishery.

The linkage between blue whiting and the Norway pout fisheries has been evaluated. Blue whiting is caught by different gears and mesh sizes and can be grouped in two types of fisheries. The first is a directed fishery for blue whiting where by-catches of other species are insignificant. These landings are used for human consumption or for meal and oil production. Secondly, there is a mixed industrial fishery for Norway pout where varying proportions of juvenile blue whiting are caught as a by-catch. The majority of these landings are for meal and oil production.

The by-catch of blue whiting in the Norway pout fishery in 2001 in Subarea IV was 52000 t and in Division IIIa 13700 t . An additional 6700 t was caught as a by-catch by the Faroese, but ACFM has not been able to verify that this was taken in a Norway pout fishery. The total blue whiting by-catch in the Norway
pout and other fisheries in Subarea IV and Division IIIa combined was 79100 t , which is $4 \%$ of the total international blue whiting landings in 2001 (1780 000 t).

Source of information: Report of the Working Group on the Assessment of Demersal Stocks in the North Sea and Skagerrak, June 2002 (ICES CM 2003/ACFM:02).

Yield and spawning biomass per Recruit F-reference points:

### 3.5.13

### 3.5.13.a Sandeel in Subarea IV

Catches for the total North Sea are given by country in Table 3.5.13.1 and by the Subareas shown in Figure 3.5.13.1 and Table 3.5.13.2.

State of stock/exploitation: The stock is within safe biological limits. SSB in 2002 is estimated to be just above $\mathbf{B}_{\mathrm{pa}}$. No fishing mortality reference points have been set for this stock. The 2001 year class is estimated to be the strongest in the time-series.

Management objectives: There are no management objectives set for this stock. There is a need to develop management objectives that ensure that the stock remains high enough to provide food for a variety of predator species.

Precautionary Approach reference points (unchanged since 1999):

| ICES considers that: | ICES proposes that: |
| :--- | :--- |
| $\mathbf{B}_{\mathrm{lim}}$ is 430000 t | $\mathbf{B}_{\mathrm{pa}}$ is 600000 t |

## Technical basis:

| $\mathbf{B}_{\mathrm{lim}}$ is 430000 t , the lowest observed biomass | $\mathbf{B}_{\mathrm{pa}}$ is set to 1.4* $\mathbf{B}_{\mathrm{lim}}$ |
| :--- | :--- |
| $\mathbf{F}_{\mathrm{lim}}$ None advised | $\mathbf{F}_{\mathrm{pa}}$ None proposed |

Advice on management: ICES recommends that fishing mortality should not be allowed to increase because the consequences of removing a larger fraction of the food-biomass for other biota are unknown. Local depletion of sandeel aggregations by fisheries should be prevented, particularly in areas where predators congregate.

Relevant factors to be considered in management: The stock can sustain current fishing mortality.

Sandeels are important prey species for many marine predators. The fishing mortality is lower than the natural mortality and multispecies analyses have indicated that when $F$ is below $M$ for these types of species the fisheries are not causing problems for their predators on the scale of the stock. Locally concentrated harvesting may cause local and temporary depletions of food for predators and, therefore, harvesting should be spread widely across the stock area.

In the light of studies linking low sandeel availability to poor breeding success of kittiwake, ICES advised for 2000 a closure of the sandeel fisheries east of Scotland (Figure 3.5.13.1). All commercial fishing was excluded, except for a maximum of 10 boat days in each of May and June for stock monitoring purposes. The closed area will be maintained for three years with an evaluation every year.

Catch forecast for 2003: The few year classes in the fishery make the stock size and catch opportunities largely dependent on the size of the incoming year classes. Traditional deterministic forecasts are therefore
not feasible. Initial estimates of the 2001 year class indicate that it is very strong.

Medium- and long-term projections: No mediumterm analysis is carried out for this stock.

Comparison with previous assessment and advice: The assessment method used for sandeel has changed since the last assessment. In general, the present method gives a slightly lower F and a higher SSB compared to the previous method. However, there are substantial discrepancies between the current assessment and previous assessments due to the addition of the 2001 data. SSB in 2001 is now estimated to be $25 \%$ lower and fishing mortality in 2000 is estimated to be $56 \%$ higher.

Elaboration and special comment: Sandeel is taken by trawlers using small mesh gear. The fishery is seasonal, taking place mostly in the spring and summer. Most of the catch consists of Ammodytes marinus and there is a low percentage by-catch by weight of TAC species.

Sandeels are largely stationary after settlement and the North Sea sandeel must be considered as a complex of local populations. Recruitment to local areas may not only be related to the local stock, as interchange between areas seems to take place during the early phases of life before settlement. The Shetland sandeel stock is assessed as a separate unit.

Source of information: Report of the Working Group on the Assessment of Demersal Stocks in the North Sea and Skagerrak, 11 - 20 June 2002 (ICES CM 2003/ACFM:
02).

Yield and spawning biomass per Recruit F-reference points:

|  | Fish Mort <br> Ages 1-2 | Yield/R | SSB/R |
| :--- | :---: | :---: | :---: |

Figure 3.5.13.1 North Sea sandeel. Sampling areas and assessments area used by ICES.

State of stock/exploitation: Safe biological limits have not been defined for this stock. It is believed that fishing mortality is well below natural mortality. This means that natural processes largely drive stock variations. Landings in 2001 were 1264 t , substantially lower than in 2000 and below the TAC of 7000 t .

Management objectives: The Shetland sandeel fishery re-opened in 1995 subject to a multi-annual management regime. This was revised for the 1998 fishing season onwards. The new regime consists of an annual TAC of 7000 t and a closure during the months of June and July. The seasonal closure is to avoid any possibility of direct competition between the fishery and seabirds during the chick-rearing season. There is also a limit on vessel size to boats of 20 m or less. These arrangements were renewed in 2001 for another three years.

## Advice on management: None.

Relevant factors to be considered in management: ICES suggested in October 2001 that the management plan be evaluated before the agreed end date. The evaluation has been carried out and all interest groups have agreed to the continuation of the current measures.

Fishing grounds are close inshore and often adjacent to large colonies of seabirds for which the sandeel population is an important food supply, especially during the breeding season. For some seabird species the availability of 0 -group sandeel as prey is very important.

In some years most of the recruitment comes from spawning areas away from Shetland. The availability of 0 -group sandeel is, therefore, not closely linked to the local spawning population. The sandeel population is also an important food source for other predator species in the Shetland area.

An assessment based on survey data alone suggests that the SSB in 2000 is close to its lowest observed value and that recent recruitment has been weak.

Elaboration and special comment: The previous assessment was undertaken in 2001 and was based on survey data only. Because fishing mortality appears to be very low compared with natural mortality, the assessment used a model, which only attempted to estimate total mortality. The assessment was consistent with the previous assessment (1997), but was subject to high uncertainty. It indicated that SSB has declined recently and that recent recruitment has been poor. If these indications are correct then the SSB is likely to decline further in the short term.

The sandeel population at Shetland is not a separate stock, but forms part of a larger complex of subpopulations. Estimates of the consumption of sandeel by seabirds and other predators greatly exceed the quantities taken by the fishery in recent years.

[^25]Sandeel in the Shetland Area

### 3.5.14.a Pandalus borealis in Division IVa (Fladen Ground)

State of the stock/exploitation: The current state of the stock is unknown. During the last 10 years total landings fluctuated between a low of around 500 t to a high of about 6000 t . Total effort has been relatively low in 1999, 2000, and 2001.

Relevant factors to be considered in management: The fishery is highly dependent on year class strength. Only age groups 2 and 3 at the beginning of the year and age groups 1 and 2 at the end of the year are caught. There is no basis for defining biological reference points for this stock.

Sorting grids or other means of facilitating the escape of fish should be implemented in this fishery.

Elaboration and special comment: No assessment was conducted in 2002.

A main characteristic of the Fladen stock of Pandalus is that the catches consist of mainly 2 age groups. During the first two quarters of the year age groups 2 and 3 normally dominate the catches. During quarter 4, age group 3 usually disappears from the catches, while age group 1 adds to the catches. Because of the few age groups constituting this stock predictions for the Fladen fishery are possible only if very reliable information on recruitment is available.

The Fladen stock is mainly exploited by Danish and UK trawlers normally using $35-40 \mathrm{~mm}$ cod-end mesh size. It is a targeted fishery on Pandalus with low by-catches of other species. In recent years the by-catch in the Danish fishery of other species was estimated to be $11 \%$ of the total landings.

Source of information: Report of the Pandalus Assessment Working Group, Charlottenlund, Denmark, August 2002 (ICES CM 2003/ACFM:05).

### 3.5.15

Anglerfish in Subarea IV (North Sea)

Anglerfish in this area is assessed as part of the complex covering Division IIIa (Skagerrak and Kattegat), Subarea IV (North Sea) and Division VIa (West of Scotland), see section 3.7.7.

## Answer to Request from EC concerning the Status of Sea Bass in European Waters

ICES has been asked by the European Commission (DG Fisheries) to provide information on bass (Dicentrarchus labrax) in response to the following questions:

1) The stock identity of bass in Community waters and, if necessary, adjacent waters in the Northeast Atlantic. How many bass stocks are there; what is their geographical extent? (Not in the Mediterranean or NW Atlantic).
2) The historical and current state of these stocks of bass. Are the stocks under-exploited, overexploited? Can ICES provide the usual time-series of biomass, fishing mortality rate, recruits, landings, yield-per-recruit plots, etc.? If possible, provide catch-at-age composition, F-at-age, and effort data by métier as a possible precursor to economic analyses to be conducted outside ICES.
3) Current problems in the exploitation of bass and provide advice on possibilities for overcoming these problems. Is exploitation in the Channel and/or Celtic Sea a problem? If so, how can it be solved?

The SGBASS Terms of Reference agreed by ACFM were to work by correspondence in 2001 and to meet in Brest from March 11-15, 2002, to:
a) compile information on European fisheries in which sea bass are taken;
b) compile information pertinent for the assessment of sea bass, including information that can be used to identify unit stocks of sea bass;
c) where possible, present assessments of sea bass stocks in European waters and identify their stock conservation requirements.

## Q1. Stock identity:

The results of tagging studies and the seasonal distribution of the fisheries taking bass in Subareas IV, VII, and VIII suggest that it may be possible to identify four sub-units for management/assessment purposes: fish which move between the Channel and the southern North Sea; fish which migrate along the west coast of Britain and into Cornish waters; fish which move between Biscay and the western Channel; and fish which remain largely within Irish waters (Figure 3.5.16.1). It should be noted that adult fish from the first three of these "stocks" are exploited to some extent by the same offshore pair-trawl fishery in winter.

## Basis for advice:

The 2001 SGBASS report (ICES CM 2001/ACFM:25) presented information which can be used to identify
stocks of bass in Community and adjacent waters in the Northeast Atlantic, and provided an interpretation in relation to potential stock assessment areas. Sea bass, D. labrax, are distributed in Northeast Atlantic shelf waters from southern Norway, through the North Sea, the Irish Sea, the Bay of Biscay, the Mediterranean, and the Black Sea to Northwest Africa, and the species is at the northern limits of its range around the British Isles and southern Scandinavia.

Sea bass spawn in the Channel and Celtic Sea from February to May and occasionally off the Isle of Man in the Irish Sea and in the southern North Sea during April - June. In the Bay of Biscay, bass spawn in two areas; in the south of Division VIIIa and close by in the north of Division VIIIb in January-March. Other spawning grounds may exist in areas that have not been sampled by pelagic trawling or by plankton surveys. Bass larvae resulting from offshore spawning move steadily inshore towards the coast as they grow and, when they reach a specific developmental stage at around $11-15 \mathrm{~mm}$ in length (at $30-50$ days old), it is thought that they respond to an environmental cue and actively swim into estuarine nursery habitats. From June onwards, 0-group bass in excess of 15 mm long are found in creeks, estuaries, and shallow bays all along the southeast, south, and west coasts of England and Wales, where they remain through their first and second years, after which they migrate to over-wintering areas in deeper water, returning to the larger estuaries in summer. Several studies indicate the existence of similar bass nursery areas in bays and estuaries on the French coasts of the Channel and Bay of Biscay.

After 4-7 years, or at approximate lengths of 35 cm for males and 42 cm for females, bass attain maturity and adopt the migratory movements of the adult fish. In general, adult bass move north and east following spawning (peak February-May), and appear to return to the same inshore feeding area each summer. The reciprocal movement of maturing fish to pre-spawning areas occurs as the water temperature decreases during October-December. The spatial and temporal distributions of recaptures of adult bass tagged in the Channel offshore fishery in winter 2000 and in the summer inshore fisheries in 2000 and 2001 suggest that the patterns of movement are similar to those previously reported from tagging around England and Wales in the 1970s and early 1980s. A higher proportion of recaptures of adult bass in the recent study, however, were recaptured late in the year in "summer" feeding areas, and also inshore in the northeastern Irish Sea, eastern Channel, and southern North Sea in February and March. This suggests that not all adult bass may partake in offshore spawning. These results show that the bass taken by pair-trawls offshore in winter prespawning and spawning areas in the western Channel are also exploited in a wide range of areas extending
from the northeastern Irish Sea to the southern North Sea.

Recaptures of bass tagged as juveniles in nursery areas around England and Wales indicate dispersal at the age of 4-6 years (around 36 cm ), often moving well outside the 'home' range and not necessarily recruiting to their parent spawning stock. This mixing of recruiting bass between regions is borne out by genetic studies. Analyses of samples of 0-group bass from Divisions IVc, VIIe, VIIf, and VIIg provide little, if any, sign of population structuring. Similarly, analysis of adult seabass captured at spawning grounds in VIIe, VIIf, and VIIIa,b indicated very limited genetic differentiation between spawning grounds. This suggests that mixing between generations is sufficient to homogenise the genetic make-up of the bass population in Northwest Europe.

The lack of genetic differentiation, and the wide dispersion of bass as they move from nursery areas to join spawning populations, provide little evidence for the existence of biological stocks within the bass population occupying the region between the Bay of Biscay, the Irish Sea, and the North Sea. However, tagging studies suggest there is little, if any, interchange of bass between Ireland and the UK.

## Q2. The historical and current state of these stocks of bass:

Exploitation of bass stocks in Northwest Europe has a long history, both in capture fisheries and extensive aquaculture using wild-caught fry. Prior to the 1980s, however, sea bass were mainly the target of small-scale inshore fisheries using lines and seine nets, and especially by recreational anglers around the British Isles. These fisheries continue today, but bass have now become an important by-catch for demersal trawlers and have been increasingly targeted by French and UK pairtrawlers fishing offshore in the winter on pre-spawning and spawning aggregations. Nominal landings by country and ICES division since 1984 are given in Tables 6.1.1.1-6.1.1.7 in the SGBASS report for 2002.

Analyses carried out by ICES using catch-at-age data indicated that fishing mortality has remained relatively stable at around $0.2-0.3$ for the years 1985, 1990, and 1995 in the southern North Sea and Subarea VII, but these results are considered preliminary and give no indication whether these levels are sustainable. CPUE time-series, which show a declining trend from 1985 to 1992 followed by a strong increase to a peak in 1994, and then generally high but fluctuating catch rates until 2000, suggest that the abundance of bass in north European fisheries has remained higher in the mid-late 1990s than in the late 1980s.

Data on year-class strength are available for Subareas IV and VII, though these are more likely to reflect the influence of environmental conditions on survival of
eggs, larvae, and juveniles than the abundance of spawning adults on the local spawning grounds. The data suggest that the pattern of above and belowaverage year classes varies throughout the range of bass, though strong year classes such as 1976 and 1989 tend to occur in all areas. The very strong 1989 year class has been followed by several year's good recruitment in the North Sea and Subarea VII.

Technical measures (MLS, EU 1990; gillnet mesh size UK 1990 and EU 1998; and closed nursery areas, UK 1990) introduced to protect juvenile bass have resulted in an exploitation pattern that shows peak recruitment at around age 6 in 1990 and 1995. Bass of this age are leaving nursery areas to join the adult stock, and are targeted by inshore fisheries whilst they are most accessible. As a consequence, much of this fishery is recruit-driven, and above-average year classes may be heavily exploited for one or two years. A yield-perrecruit analysis, using the output from an equilibrium age-based VPA, suggests that the resource is not overexploited in growth terms, and the recent occurrence of above-average year classes indicates that it is not subject to recruit over-fishing. Further evidence that the current level and pattern of exploitation could be sustainable is provided by the observation that considerable numbers of fish in the $15+$ group were recorded in UK and French landings from VIIe, h in 1995, and length distributions for 2000 show no overall reduction in large fish through the 1990s. It has not yet been possible to determine biological reference points for sea bass.

Whilst ICES is confident that the information presented in the SGBASS report (ICES CM2002/ACFM:11 Ref. G) is a fair representation of what is happening in the bass fisheries of those sea areas for which data are currently available, i.e. the North Sea, Channel, west coast of Britain, and Biscay, it recognises that more robust analyses are required to provide advice on the management requirements of fisheries that take bass. Time-series of landings by country and sea area are already available, and catch-at-age data are being brought up to date. Whilst all UK metiers taking bass (including the recreational boat sector) are sampled for catch (discards are negligible given the package of technical measures and high value of small bass) and effort, further work is planned to improve our knowledge of French small-boat fisheries (including the recreational sector), and it is likely that data will be available in 2003 to enable an evaluation of technical interactions and economic factors.

## Q3. Management considerations:

The above analysis indicates that there are no problems with the exploitation of bass in relation to overall yield-per-recruit or recruitment over-fishing in the North Sea, Channel, west coast of Britain and Biscay, though the population structure has certainly changed since data were first collected in the 1970s. In all areas, the high abundance of fish $>20$ years old associated with a
virtually unexploited population has now declined, though strong cohorts are still recognisable at age 15+, and the incidence of above-average year classes has increased in the 1990s. This is particularly noticeable in the North Sea and Channel (where climate warming may be more apparent), and there appears to be an eastwest decline in bass production as the species extends its range through the North Sea.

In Irish waters, the decline in large bass through the 1970s and 1980s led to a policy banning its commercial exploitation in favour of recreational fishing and tourism. These are also important in the UK and France, where recreational anglers co-exist with inshore artisanal fishermen who regard bass as a valuable seasonal source of income. There is some conflict between these fisheries, but the main problem is that inshore fishermen are most affected by the technical measures protecting bass under 36 cm (for which there is a strong market) and they perceive that the benefits of their conservation accrue to the offshore pair trawl fishery taking adult bass.

ICES is aware that there is an incidental by-catch of small cetaceans in the bass pair trawl fishery, and also that trials with separator panels are planned to ameliorate this problem. ICES has advised that "harbour porpoise populations are threatened by by-catch in
[some] fisheries" (ACE 2001), and expressed concern about the sustainability of by-catch rates for other small cetaceans on several occasions through the 1990s. Although sea bass fisheries are not a primary source of by-catch mortality, ICES strongly encourages the testing and, where they are shown to be effective, adoption of technical measures to reduce cetacean bycatch in fisheries for sea bass.

Although bass stocks in Divisions IVb,c and VIIa,d,e,f,g,h, appear to be fished with an exploitation pattern that avoids growth over-fishing and at a fishing mortality level which is sustainable, given the uncertainties in the assessments and the possibility that an unfavourable change in environmental conditions may negatively influence recruitment, ICES considers that fishing mortality should not be allowed to increase. Bass is currently a non-TAC species, and management by quota is not seen as an appropriate tool for the small boat fisheries that account for the major part of landings and in which monitoring and enforcement of catch controls would be impractical. With the exception of Ireland, there is no management objective for this fishery, but it would be prudent to limit the effort of the vessels with the largest catching capacity. Ring-fencing the current participants in the pair-trawl fleets (which are subject to a weekly landings quota of 5 t per vessel) by licensing would be one option.

Figure 3.5.16.1 The sea areas in which four tentative stocks of bass are found, A) North Sea - Channel; B) Biscay; C) UK west coast, and D) Ireland. Arrows indicate the known migrations of adult bass between summer feeding areas and spawning areas to the south and west.

### 3.5.17 Advice on Multiannual TAC Arrangements and Recovery Plans

## 1) Technical Review

ICES is requested to review the scientific, statistical, biological, and technical basis for the results described in the report "Analysis of possibilities of limiting the annual fluctuations in TACs"; Reference FISH-2000-02-01. If such basis is found to be satisfactory, ICES is requested to consider, with reference to that report and any other relevant information, the following questions on targets and limits and on recovery plants. For the purposes of addressing these requests, the Commission has requested Dr L. Kell (CEFAS Lowestoft) to provide detailed access to the database of simulation results corresponding to the report.

## 2) Targets and limits

The EC is seeking to establish target fishing mortalities and corresponding limits on the amounts by which TACs may vary between years.

ICES is requested to consider, for flatfish stocks, the following target fishing mortalities and associated limitations on interannual TAC variability (in brackets):

## Plaice in the Skagerrak: 0.4 (10\%)

Plaice in the North Sea: 0.3 (10\%)
Plaice in the Irish Sea: 0.3 (10\%)
Plaice in the Eastern English Channel: 0.4 (10\%)
Sole in the North Sea: 0.25 (20\%)
Sole in the Eastern English Channel: 0.25 (20\%)

For these values, ICES should consider:
a) Conformity with criteria of sustainability, precautionary management, catch stability, and high yield.
b) The robustness of appropriate values to alternative biological hypotheses.

ICES should propose any alternative values for fishing mortality and limits on TAC changes that it considers conform better to the aforementioned criteria than the values tabulated above.

## 3) Recovery Plans

The abovementioned targets and limits would apply once the spawning stock biomasses exceed precautionary levels ( $\boldsymbol{B}_{p a}$ ). The European Commission wishes to be informed of the consequences of alternative programmes for altering fishing mortality from present levels to those proposed above. To that end, ICES should illustrate in detail the consequences of applying alternative TAC-setting rules (as set out in Table 3.3.1.2 of the report in question):
a) A 10\% annual change in fishing mortality;
b) A $50 \%$ annual change in fishing mortality;
c) A linear reduction in fishing mortality, proportionate to the amount by which spawning biomass is less than $\boldsymbol{B}_{p a}$;
d) Applying a maximum catch corresponding to historic catch;
e) Any other programmed approach for altering fishing mortality considered suitable by ICES.

For these cases, ICES is asked to illustrate the likely development of yield, fishing mortality, and stock biomass, using stochastic methods where appropriate.

## 1) Technical Review

It was not possible for ICES to check all details of the software used for this work, so the review focussed only on the approach and the results presented. These represented a substantial volume of work, which was nonetheless well presented. With regard to the operating model used, many sources of natural variation and error were simulated, but some important components of uncertainty and bias were not considered. Some elements of process error (e.g., variation in natural mortality and maturity) were not simulated. The inaccuracy of assuming no discards in assessments is not included in estimation errors. Bias in projections (including retrospective bias in the assessment as well as inaccurate assumptions in projections) was not explicitly simulated. However, many flatfish forecasts tend to overestimate SSB. In addition, the modelling assumed that the TACs were taken, i.e. no error was assumed in the implementation in the advice. However, the catches often do not correspond to the TAC. ICES understands that most of these constraints were specified by the client, so comments about the absence of these effects are not intended as a criticism of the work that has been done. Inclusion of all of these components of variation would be difficult to reliably simulate, but ignoring such variation considerably underestimates the uncertainty involved in implementing the various management scenarios.

A second limitation of the methods is the unknown Effect of statistical assumptions on the results. Unfortunately, there is little guidance on the nature of variability in process error and different assumed distributions can have different systematic affects on simulations. For example, the stochastic simulations often converge on different equilibria than indicated by deterministic calculations.

ACFM finds that the scientific basis of the operating model is sound, and results are reliable for providing management advice with some provisions. Because not all sources of bias and uncertainty were simulated and risk and bias may be under-estimated, ACFM concludes
that the results reported in "Analysis of possibilities of limiting the annual fluctuations in TACs" (Reference FISH-2000-02-01) should be interpreted with care and conclusions should be based on comparative patterns rather than on absolute estimates of probability or risk.

## 2) Targets and limits

The basic management scenarios that were investigated consisted of a target F and a constraint on the annual percentage changes in TAC, which would be permitted. The results from these scenarios were presented in terms of mean yield and the risk of the SSB being below $\mathbf{B}_{\mathrm{pa}}$.

In general, ACFM observed a non-linear relationship between risk of SSB being reduced to less than $\mathbf{B}_{\mathrm{pa}}$ and the magnitude of TAC constraints. In most short- and medium-term simulations, a TAC constraint of $10 \%$ (i.e., restricting annual changes in TAC to $10 \%$ or less) had substantially greater risk than a $20 \%$ constraint, but the difference in risk of from $20 \%$ to $40 \%$ constraints was much less. It was also clear that the current state of the stock also had an important effect on the results. For stocks below $\mathbf{B}_{\mathrm{p}}$, imposing a restrictive constraint on the TAC delayed recovery and thus led to an increased risk to the stock. Conversely, for stocks above $\mathbf{B}_{\mathrm{pa}}$, such a TAC constraint served to reduce the risk to the stock. For several stocks, the projections indicated a clear optimum target F for minimising risk and maximizing yield in the medium or long term.

Results from the individual stocks are summarized below, together with the current perception of the state of each stock.

> Plaice in the Skagerrak ( $2001 \mathrm{SSB}=\mathbf{1 3 0} \% \mathrm{~B}_{\mathrm{pa}}, 2001$ $\mathrm{~F}=112 \% \mathrm{~F}_{\mathrm{pa}}, \mathrm{F}_{\mathrm{pa}}=\mathbf{0 . 7 3}$ ):

A $10 \%$ TAC constraint has substantially greater risk than looser constraints, and risk is similar at various levels of F. For example, in the short-term, a target F of 0.4 with a $20 \%$ TAC constraint produces approximately one-third of the risk produced with a $10 \%$ TAC constraint and also produces some gains in yield. Although simulation results are sensitive to the assumed stock-recruit model, this pattern is similar for all assumed models. In the medium term, a $10 \%$ constraint also produces greater risk, and F has slightly more effect on risk, but only affects yield at very low Fs. In the long-term, the TAC constraint has less effect, and risk is much more a function of F , because the stock is fluctuating less and is nearly in equilibrium. The target $F$ that produced the greatest yield and least risk in the long term was 0.275 . In conclusion, the $10 \%$ TAC constraint appears to be too restrictive, because it does not allow a quick response to strong recruitment or poor conditions. Furthermore, target F should be less than $\mathrm{F}_{\mathrm{pa}}$.

Plaice in the North Sea ( 2001 SSB= $96 \%$ B $_{\text {pa }} 2001$ $\mathrm{F}=143 \% \mathrm{~F}_{\mathrm{pa}}, \mathrm{F}_{\mathrm{pa}}=\mathbf{0 . 3 0}$ ):

In the short-term, risk is more affected by the target F than the level of TAC constraint, because simulations are starting with SSB levels that are less than $\mathbf{B}_{\mathrm{pa}}$. Alternative stock-recruit models produced similar results. In the medium-term, yield is similar among all scenarios, but risk is greatly increased at greater target Fs. In the long term, target Fs greater than 0.35 produce less yield and great risk, with TAC constraints also producing less yield. There was no clear optimum target F for minimizing risk and maximizing yield in the long term. In conclusion, there is substantial risk of SSB being below $\mathbf{B}_{\mathrm{pa}}$ in the short, medium and long term when the target is $\mathbf{F}_{\mathrm{p}}$, regardless of TAC constraints.

Plaice in the Irish Sea ( $2001 \mathrm{SSB}=179 \% \mathrm{~B}_{\mathrm{pa}} 2001$
$\left.\mathrm{~F}=69 \% \mathrm{~F}_{\mathrm{pa}}, \mathrm{F}_{\mathrm{pa}}=\mathbf{0 . 4 5}\right)$ :

In the short term, the more restrictive TAC constraints have less risk than looser constraints, because simulations are starting with SSB levels that are much greater than $\mathbf{B}_{\mathrm{pa}}$ and low Fs, and constraints do not allow F to quickly increase to the target. Risk is lower at low target Fs, but there is substantial loss in yield. A target F of 0.363 produces much less risk than $\mathbf{F}_{\mathrm{pa}}$ with no loss of yield for much reduced risk. Yield is much less at target Fs of less than 0.275. In the long-term the $10 \%$ TAC constraint produced relatively high risk and low yield. There is substantial risk of equilibrium SSB produced by a target of $\mathbf{F}_{\mathrm{pa}}$ being less than $\mathbf{B}_{\mathrm{pa}}$. The target F that produced the greatest yield and least risk in the long term was 0.275 . In conclusion, the $10 \%$ TAC constraint appears to be too restrictive. Furthermore, target F should be less than $\mathbf{F}_{\mathrm{pa}}$.

## Plaice in the Eastern English Channel (2001

 $\mathrm{SSB}=119 \% \mathrm{~B}_{\mathrm{pa}} 2001 \mathrm{~F}=\mathbf{1 1 6} \%_{\mathrm{pa}}, \mathrm{F}_{\mathrm{pa}}=\mathbf{0 . 4 5}$ ):In the short term, the more restrictive TAC constraints have less risk than no constraints, because simulations are starting with SSB levels that are much greater than $\mathbf{B}_{\mathrm{pa}}$. In the medium term, $\mathbf{F}_{\mathrm{pa}}$ produces the most yield at low risk. In the long term target Fs greater than $\mathbf{F}_{\mathrm{pa}}$ produce much less yield and have much greater risk. The $10 \%$ TAC constraint substantially increases risk, particularly at higher target Fs. Simulations at lower Fs produce SSBs that are much greater than the observed maximum. In conclusion, the $10 \% \mathrm{TAC}$ constraint appears to be too restrictive, but $\mathbf{F}_{\mathrm{pa}}$ appears to produce low risk and high yield.

Sole in the North Sea ( 2001 SSB=113\%B ba $_{\text {pa }} 2001$ $\mathrm{F}=\mathbf{1 1 5 \%} \mathrm{F}_{\mathrm{pa}}, \mathrm{F}_{\mathrm{pa}}=\mathbf{0 . 4 0}$ ):

In the short term, target $F$ and to a lesser extent TAC constraints affect on risk. Target Fs greater than 0.5 produce a very high risk, with or without TAC constraints. At lower target Fs, TAC constraints have more affect on risk. The $10 \%$ TAC constraint produces substantially greater risk than looser constraints, irrespective of target Fs, probably resulting from highly variable recruitment. The $10 \%$ TAC constraint is also much riskier in the medium term. In the long term, risk is more a function of $\operatorname{target} \mathrm{F}$, with losses in yield at Fs greater than 0.4 . There was no clear optimum target F for minimizing risk and maximizing yield in the long term. In conclusion, the $10 \%$ TAC constraint appears to be too risky, but a $20 \%$ TAC constraint with a target F of $\mathbf{F}_{\mathrm{pa}}$ or less has substantially less risk.

Sole in the Eastern English Channel (2001 $\mathrm{SSB}=\mathbf{1 5 8} \% \mathrm{~B}_{\mathrm{pa}} 2001 \mathrm{~F}=\mathbf{8 5} \% \mathrm{~F}_{\mathrm{pa}}, \mathrm{F}_{\mathrm{pa}}=\mathbf{0 . 4 0}$ ):

In the short term, there is a distinct tradeoff between risk and yield in which target Fs greater than $\mathbf{F}_{\mathrm{pa}}$ have substantially greater risk, but also produce greater yield.

The $10 \%$ TAC constraint also has greater risk for the lower target Fs. The target F that produced the greatest yield and least risk in the medium term was 0.3 , but the $10 \%$ TAC constraint had greater risk at all target Fs. The target F that produced the greatest yield and least risk in the long term was $0.2-0.3$, and the $10 \%$ TAC constraint was more risky. In conclusion, the $10 \%$ TAC constraint appears to be too risky, but a $20 \%$ constraint with a target $F$ of between 0.2 and 0.3 has relatively low risk and produces relatively high yields.

## 3) Recovery Plans

This request could not be completely addressed with the information that was provided, because the proposed rebuilding strategies were not directly simulated. Although ACFM cannot respond to the specific request, the general simulation results show that TAC constraints should be not be applied during rebuilding and TACs should be as responsive as possible to the perceived stock conditions. One technical aspect of a rapid response is that some assessment methods that assume stable F may not perform well for monitoring rebuilding.
