# 1 Introduction

It might be argued that in the final years of the second Millennium, when the storage, analysis and exchange of information have been more or less taken over by electronic technology, there is no longer any need for a publication consisting almost entirely of tables. However, although the coordinators of the Stomach Sampling Project in the North Sea in 1991 acknowledge gratefully the essential role now played by computers in handling as a matter of routine large and complex data sets that would have been regarded as unmanageable two or three decades ago, we believe that paper records are still valuable. Our reasons are as follows:

- It is important that large-scale coordinated exercises like the one described here are officially documented, if only as a benchmark in ICES history. To this end, it is appropriate to publish a permanent record of the project, in which the background, execution, problems encountered and some of the principal results are described.
- The main "deliverable" of the Stomach Sampling Project in the North Sea in 1991 was a rather small set of numbers that was fed to the ICES computer and voided in a more or less unrecognisable form as output from Multispecies Virtual Population Analysis (MSVPA). This application uses only part of the information collected in 1991. The complete data set is far more extensive and provide further insight into the ecology of and interactions between North Sea fish. A printed document is an effective way of advertising the existence of information which is available in digital form to workers unfamiliar with the project. It also provides the opportunity to document the limitations and the possible pitfalls in using the basic data, which will not be immediately apparent from the computer records.

Furthermore:

- Printed documents are a convenient and "user-friendly" way of comparing large sets of data.
- Last, but by no means least, a formal publication is a tangible memorial to the heroic efforts of those many members of the ICES community who assisted in the collection and analysis of nearly 100,000 fish stomachs.

We have adhered to the general layout of the Data Base Report of the Stomach Sampling Project 1981 (Daan (ed.) 1989 - ICES Cooperative Research Report 164). The object of this constructive plagiarism is to make it relatively easy to compare the results of these two major stomach sampling projects. However, there are some significant differences between the data presented in the two reports:

- Table 8 includes additional categories of commercially exploited prey.
- The analytical programs used to generate Tables 10, 11, 12 and 13 have been modified. When the 1981 data were processed, the programs applied to the cod and haddock stomach contents did not take partially identified prey into account. Most of the commercial fish prey that had been identified only to family level is now distributed over individual species, for all predators. Also, some of the sandeel data may not have been included in the earlier analyses. This omission has been rectified.
- Table 10 has been completely redesigned. In the previous report the size composition of each MSVPA fish prey species in the stomach of each predator age class was given, for each sampling area. We believe that the revised version, which gives the size composition of each of the MSVPA fish prey species in the stomach of each predator size class, has more ecological significance. Also, information is given for a wider spectrum of commercially exploited non-MSVPA fish species and crustaceans.
- Table 13 (estimated mean weights of MSVPA prey at the time of ingestion) is also fundamentally different from its predecessor. The weights in this report have been estimated by multiplying the observed weights in the stomachs by 1.6. A multiplying factor of 2.0 was used in all earlier reports.

Very few comparisons between 1981 and 1991 are made in the body of this report, other than to highlight similarities and differences between sampling levels and processing methods. It is to be hoped that the results of detailed analyses will eventually be published elsewhere.

Although we believe that the tables presented in this report are valuable in their own right, we must reiterate that they are only examples of the many possible uses which can be made of the database. One of our aims is to encourage other workers to obtain copies of the exchange tapes from the ICES Secretariat so that they can themselves explore the basic data. However, we recommend that they should first read the text of this document, and some of the reports cited herein, to gain an understanding of the underlying strengths and weaknesses of our work.

# 2 Background and chronology

The North Sea Stomach Sampling Project in 1981 ("the Year of the Stomach") is an excellent example of the large-scale, international, cooperative programmes of applied biological research at which fisheries scientists excel. A full description is given in Daan (ed.) 1989. The prime purpose of the 1981 project was to provide a set of feeding data which could be used to test the relatively

new art of multispecies virtual population analysis (MSVPA) (Sparre, 1991; Magnusson, 1995). The outputs from the first MSVPA trials provided fresh insights into the nature and extent of the predatory interactions between the principal exploited fish species in the North Sea. MSVPA revealed that commercially exploited species were eating very large numbers of other commercially exploited species. In particular, it was found that the mortality inflicted by the five predator species included in the MSVPA on small, short-lived species such as Norway pout, sprat and sandeels and on the youngest age classes of the larger species was extremely high. Larger fish were shown to be much less vulnerable to predation by fish.

Prior to the trials of MSVPA, most of the "traditional" virtual population analysis (VPA) single-species assessments of North Sea fish stocks were based on the assumption that the instantaneous rate of natural mortality,  $M$ , did not vary with age. A value of  $M = 0.2$  was frequently assigned to each of the age cohorts included in the analysis. The initial trials with MSVPA indicated that it was unrealistic to assume that  $M$  is constant with age and demonstrated that  $M$  could be much larger than 0.2. Revised estimates of  $M$ , which take into account some of the findings of MSVPA, are now used in many of the single-species assessments.

Because the values of  $M$  used in routine stock assessments have in many cases been revised in the light of the results of MSVPA, the short-term predictions for many North Sea fish stocks given by VPA and MSVPA, respectively, are now in reasonably close agreement. However, there are discrepancies between the medium- and long-term forecasts, which have important implications for management strategies (Daan, 1987). Furthermore, multispecies considerations may even have an important bearing on short-term management advice in regions such as the Baltic, where the fish stocks are part of a relatively simple system, and changes can be rapid (Hilden, 1991).

Although additional information on the diet of cod, whiting and saithe was collected in the first and third quarters of 1985, 1986 and 1987 (ICES, 1988a), the MSVPAs carried out in the years 1983-1990 relied to a large extent on the feeding data collected in 1981. However, because it was already apparent in the mid-1980s that the relative abundance of some of the major exploited fish species had changed markedly with respect to 1981 the Multispecies Assessment Working Group recommended that a full-scale stomach sampling programme be repeated in 1991 in order to extend the basis for multispecies assessment (ICES, 1988b) and to test the hypothesis that prey suitabilities remain constant from year to year. This recommendation was endorsed during the 76th Statutory Meeting of the ICES, when it was resolved (C Res 1988/2:12) that a Planning Group would be established under the chairmanship of Dr N Daan to:

- a) define the requirements, priorities and logistics of a large-scale stomach sampling programme to be undertaken in 1991;
- b) to submit a detailed proposal to the Statutory Meeting in 1989.

The Planning Group met in Lowestoft in April 1989. It was agreed that the first aim of the new project should be to obtain a reliable new data set on the food composition of the five main predator species in the North Sea (cod, haddock, whiting, saithe and mackerel) for use in MSVPA, maintaining compatibility with the results from 1981. It was decided that sampling would be extended to include the 0-groups of these five priority species. This age class was incompletely sampled in 1981, but there is evidence that significant predatory interactions may take place both within and between species during the 0-group phase. In addition, the Planning Group recognised that a number of other predators might consume significant numbers of MSVPA species. They recommended accordingly that the stomachs of scad, *Trachurus trachurus*, grey gurnard, *Eutrigla gurnardus*, and all species of rays, *Rajidae*, should be sampled throughout 1991, on the grounds that these fish are known piscivores and their biomass in the North Sea is believed to be large. It was also agreed that herring and sandeels, which prey on the eggs and larvae of other MSVPA species, should be sampled in spring.

The logistics of sampling were discussed at some length. It was agreed that the priority predators could be adequately sampled by deploying a minimum of three vessels in each quarter. The first and third quarters of 1991 would be covered by ongoing or planned surveys, but it was recognised that additional bottom trawl cruises in the second and fourth quarters would be needed, as well as special cruises dedicated to sampling the pelagic 0-group phase of the primary predators. It was noted that there was no coordination of the various national bottom trawl surveys of the North Sea, except for the International Young Fish Survey (IYFS), which takes place in the first quarter of each year. The Group decided that ICES should be asked to establish a North Sea Bottom Trawl Survey Working Group to take the place of the existing "IYFS Working Group".

It was agreed that the Stomach Sampling Project should be managed by an overall Project Coordinator and a group of species coordinators. Dr J R G Hislop (UK Scotland) was chosen to coordinate the project and species coordinators were appointed as follows:

- H J L Heessen (The Netherlands) - cod  
A P Robb (UK Scotland) - whiting  
D Skagen (Norway) - mackerel  
H Gislason (Denmark) - saithe  
P J Bromley (UK England) - 0-group gadoids  
H Sparholt (Denmark) - rays  
N Daan (The Netherlands) - gurnards, scad, other species

No coordinator for haddock was appointed during the meeting, but A Temming (Germany) subsequently volunteered to be responsible for this species.

The report of the Planning Group included the following recommendations (ICES, 1989):

- a) A stomach sampling programme comparable to that in 1981 be conducted in 1991 and that Dr J. R. G. Hislop acts as the project coordinator.
- b) Countries are strongly urged to make available i) extra ship time in order to achieve a quarterly coverage of the total North Sea; and ii) manpower to allow the analysis of the samples within a reasonable time span.
- c) The ICES gives consideration to the formation of an International Bottom Trawl Surveys Working Group to co-ordinate effort and standardise gears and methods of bottom trawl surveys within the North Sea, Skagerrak and Kattegat.
- d) The ICES Working Group is requested to consider the redeployment of some effort from the 1991 survey to the second and/or fourth quarter of that year to provide improved coverage to the Stomach Sampling Project.
- e) The species coordinators meet in Aberdeen at the end of 1990 or early in 1991 to prepare a revised version of the Manual for the North Sea Stomach Sampling Project.

These recommendations were endorsed during the 77th Statutory Meeting in 1989 (C Res 1989/4:9, C Res 1989/2:12, C Res 1989/2:13).

One outcome of C Res 1989/2:13 proved to be of great significance to the success of the stomach sampling project. During the first meeting (in Feb/March 1990) of the newly established International North Sea, Skagerrak and Kattegat Bottom Trawl Survey Working Group (the successor to the "IYFS Working Group", later renamed the International Bottom Trawl Survey Working Group (IBTS WG), it was proposed that four quarterly coordinated bottom trawl surveys should take place in the North Sea, Skagerrak and Kattegat for a period of five years, starting in 1991 (ICES, 1990). ICES adopted this proposal in 1990 and requested national laboratories to make available ship time for these surveys (C. Res. 1990/4:3). The quarterly surveys were the source of most of the stomachs sampled in 1991.

The Manual for the ICES North Sea Stomach Project in 1991 (ICES, 1991) was prepared by the species coordinators in Aberdeen in January 1991, just in time to be distributed to most of the participants in the International Young Fish Survey (IYFS). This document gives detailed instructions on sampling levels, size classes of predators and prey, the classification of stomachs,

sample documentation etc. It also includes the original specifications of a stomach data exchange tape (although these specifications were subsequently revised - see below). The Manual contains the following Recommendations:

The Planning Group should meet in IJmuiden during the period 23-28 April 1992, under the Chairmanship of Dr J. R. G. Hislop in order to:

- a) Prepare a progress report on the 1991 Stomach Sampling Project.
- b) Resolve logistical problems that may have emerged during the sampling, analysis and computerisation of the data.
- c) Compile the auxiliary information on age length keys, survey data etc needed for preparing the stomach data for the MSVPA model.

This Recommendation was adopted during the 79th Statutory Meeting at La Rochelle (C Res 1991/2:13).

In their Progress Report (ICES, 1992a), the Planning Group presented preliminary information on the numbers of stomachs that had been sampled in 1991, the numbers analysed to date and the whereabouts of samples that had not yet reached their final destination. The meeting provided the opportunity to discuss problems that had arisen during the collection of samples and in the analysis of stomach contents. These are documented in the Progress Report. The Progress Report also contains the definitive specifications of the data exchange tape (Appendix I), which were agreed during the meeting of the Study Group on the Analysis of Feeding Data in March 1992 (ICES, 1992b). The Report recommended that the species coordinators of the 1991 Stomach Sampling Project should meet again in IJmuiden in September 1993 to prepare the input data for MSVPA. This Recommendation was adopted by the ICES during the 80th Statutory Meeting (C Res 1992/2:14).

During their meeting in IJmuiden the species coordinators prepared most of the input data for MSVPA within the allotted time. The remaining loose ends were tidied up after the meeting and the MSVPA input data were sent to Copenhagen in October 1993. The species coordinators did not submit a formal report on their meeting to ICES, but they prepared a substantial working paper. That paper was tabled at the subsequent meeting of the Multispecies Assessment Working Group, which took place in Copenhagen (23 November-2 December 1993) under the chairmanship of Dr J. Rice. Parts of the working paper were included in the report of the MSVPA WG (ICES, 1994) and other parts have been incorporated into the present document.

Early in 1995, during the preparation of the present report, it was discovered that some of the data supplied to the MSVPA Working Group in 1993 were incorrect.

Extensive checks were made in IJmuiden, and an error was detected in the software used to generate the inputs to MSVPA. After some of the files and programs had been modified, new data were sent to Copenhagen in March 1995 and used during the meeting of the MSVPA WG in June, 1995 (ICES, 1996a). Further changes to the programs were made in 1996 (ICES, 1996b). These are described in Section 6.6.

### 3 Sampling methods

Only a brief description of the sampling methods will be given here. The Project Manual (ICES, 1991) should be consulted for a comprehensive account of the agreed protocol.

The primary purpose of the exercise was to determine the weights and numbers of each age class of each MSVPA species eaten by an average predator of each age over the course of the year. Because both the rate of food intake and the composition of the diet are likely to vary with respect to time of year, and the diet is likely to show spatial variation, samples were stratified by season (three-monthly period) and by area (ICES statistical rectangle, Figure 1). Furthermore, because it is not practicable to age large numbers of individual fish at sea, samples were stratified by predator size class, rather than by age class. The size strata used in 1981 were relatively coarse (most class intervals were 5 cm or more). In consequence, the transformations from size-stratified data to age-stratified data were rather crude. Several of the original size classes were sub-divided in 1985 and further refinements were made in 1991 (Table 4).

Very few predators measuring less than 10 cm were sampled prior to 1991. This was a deliberate decision, because it was thought unlikely that these small individuals would prey on fish to any great extent. However, the results of the earlier exercises indicated that even small fish may be piscivorous. It was therefore agreed that fish measuring 5 cm and above should be sampled in 1991. This provided full coverage of the size ranges occupied by the 1-group predators throughout the year and of the demersal phase of the 0-groups in the latter part of the year.

The overwhelming majority of the stomachs were collected during the quarterly International Bottom Trawl Surveys of the North Sea (IBTS), which involved nine research ships belonging to seven nations (ICES, 1992c). Participants were requested to sample stomachs from at least one haul in each statistical rectangle in each quarter. The sampling targets are given in Appendix II. The IBTS contributed very substantially to the success of the Stomach Sampling Project. Not only did they provide good spatial coverage of the North Sea in each quarterly period, but also the fact that there was a considerable degree of standardisation of gear and fishing methods meant that the auxiliary data derived from the surveys,

which are used to process the basic data (see Section 5) were reasonably homogeneous. Some stomachs were also collected during other research vessel surveys and on commercial vessels.

The weight and composition of the stomach contents of a typical member of the predator population is estimated by multiplying the average stomach contents of those fish that were still digesting a meal when captured (feeding fish) by a factor that accounts for the fact that not all members of the population are actively feeding at any one time (Section 5). It is therefore necessary to record how many of the sampled fish had empty stomachs (ie non-feeding fish).

However, in practice it is difficult to distinguish between feeding and non-feeding fish because some feeding fish may have regurgitated all or part of their stomach contents by the time they are examined. It is not always immediately obvious that regurgitation has occurred, and the classification of stomachs tends to be rather subjective. However, the presence of food remains in the mouth and gullet is direct evidence of regurgitation and aquarium experiments (Robb, 1992) have shown that the size and the colour of the gall bladder are a useful guide to the recent feeding history of whiting.

The usual sampling procedure was to select from the catch the numbers of fish to be sampled in each size class (Appendix II), rejecting any fish with everted stomachs. The fish were then opened and classified as either F (feeding, valid), R (feeding, regurgitated), SR (stomachs containing only indigestible skeletal remains, such as fish otoliths, molluscan opercula, polychaete chaetae etc) or E (empty). The sample kept for examination in the laboratory consisted of stomachs classed as F, SR or E. Regurgitated stomachs (R) were not retained, on the grounds that their contents, if any, were not fully representative of feeding fish. Whenever possible, stomachs in this category were replaced in the sample with an equivalent number of "valid" stomachs (F). If there were not enough F stomachs in the catch to permit this substitution, the number of regurgitated stomachs was recorded to ensure that the proportion of feeding fish in the sample was evaluated correctly.

It would have been highly desirable to store and analyse each stomach separately, so that the variance in the stomach contents could be calculated. However, the Planning Group realised that space and time were likely to be limiting factors. Although the species coordinators were encouraged to process individual stomachs, it was agreed that all stomachs within a size stratum could be stored in the same container and it would be acceptable to work them up as a pooled sample. In practice, many of the stomachs were worked up individually. Further information can be obtained from the species coordinators.

All the stomachs collected in 1981 were preserved in formaldehyde solution or (rarely) in alcohol. Since that

time there has been a growing recognition that exposure to formaldehyde may be a health risk and the use of this preservative has been either prohibited or strictly controlled in several national institutes. It was therefore necessary to use other means to preserve some of the stomachs sampled in 1991. For example, all the stomachs sampled aboard Norwegian vessels were preserved by freezing. Prey weights and lengths were not corrected for the effects of preservation.

## 4 Analysis of stomach contents

Every effort was made to identify commercially exploited fish and crustaceans to species level, and to record the numbers and weight within each prey size class. Although the main purpose of the exercise was to provide a new set of input data for MSVPA, the contents of fish stomachs can provide valuable ecological information on the geographical distribution of individual prey species and a detailed analysis is therefore highly desirable. However, the Planning Group recognised that if the material was to be worked up within a reasonably short period of time, some short cuts, such as identifying many of the invertebrate prey only to major taxonomic groups, might be necessary. The level to which these "other" food items were identified was left to the discretion of the species coordinators.

Prey names were coded using the ten-digit system devised in the USA by the National Oceanographic Data Center (NODC). A list of scientific names and their associated NODC codes was available at the start of the project (see ICES, 1991 for a list of the most important codes). When prey which had not been coded previously were identified during the analysis of the 1991 stomachs, their scientific names were forwarded to IJmuiden, where they were given provisional codes and added to a central data base. The names of these "new" items will be forwarded to the NODC where they will be assigned official codes. Although assigning temporary codes to "new" prey is necessary to ensure that data can be processed rapidly, it can lead to problems. In 1981 many species of fish and invertebrates that are common in the North Sea had not yet been included in the NODC list. Provisional codes, assigned on an *ad hoc* basis, were used to process the data. However, this pragmatic approach had some pitfalls; when an updated list was received from the NODC, it was discovered that the provisional 10-digit codes given to whiting, *Merlangius merlangus*, and poor cod, *Trisopterus minutus*, were now transposed. The stomach contents database was subsequently recoded to conform with the NODC classification.

## 5 Data processing

### 5.1 Basic Data Processing

There is no unequivocally "correct" way to transform the basic stomach contents data into the form required as input to MSVPA. In 1981 the species coordinators were left to their own devices and there were some fundamental differences between the methods employed to attain the required end product. Only cod and haddock were worked up in an identical manner. There was much more conformity in 1991. The individual species coordinators were free to use any method they chose to file the raw stomach contents data, but it was agreed that the data would have to be made available in a standard format on magnetic tape (Appendix B). These exchange tapes, which contain the basic data in a fully disaggregated state, were used to generate the files required as input to a suite of analytical software (the ISR programs) developed at RIVO-DLO by Niels Daan. These programs combine stomach contents with data on catch rates and age/size distributions to produce a number of standard summary tables, as well as generating the arrays of numbers and weights of prey of each age in the stomachs of predators of each age required as input to MSVPA. Most of the tables presented here are standard outputs from the ISR programs.

The first stage in the analysis is to calculate the average composition of the stomach contents of each predator species/size class combination on a haul (sample) basis. This was done by pooling the data from the individual stomachs and applying the following relationship:

$$W_s = \frac{W_{TOT}}{N} \cdot \frac{(N_F + N_{SR} + N_R)}{N} \quad (1)$$

where	$W_s$	= average weight of stomach contents in a haul (sample)
	$W_{TOT}$	= weight of prey in all stomachs sampled
	N	= number of stomachs sampled (= sample size)
	$N_F$	= number of feeding (valid) stomachs
	$N_{SR}$	= number containing only skeletal remains
	$N_R$	= number of feeding (regurgitated) stomachs

When a statistical rectangle was sampled more than once, the rectangle value was calculated as the weighted mean of the haul (sample) values, the weighting factors being the numbers of stomachs from each haul that had been sampled. (NB: In the previous North Sea stomach sampling projects the rectangle value was obtained by applying Equation 1 to the pooled haul data (Daan, (ed.),

1989). However, the two methods give virtually identical results.).

The next step is to calculate the average composition of the stomach contents of a predator of a given size within a specified geographical area. The ISR programs permit four options:

- i) The statistical rectangle values are averaged, disregarding the numbers of stomachs sampled within each rectangle.
- ii) The statistical rectangle values are weighted by the sample size (number of stomachs examined within the rectangle).

Neither of these options takes predator abundance into account. The remaining options use the trawl survey catch rates as indicators of within-rectangle predator abundance:

- iii) The statistical rectangle values are weighted by the catch rates (mean number caught per hour fishing) within the rectangle.
- iv) The statistical rectangle values are weighted by the square root of the catch rates; this reduces the influence of occasional very large catches.

Any one of these area values can then be converted into arrays based on predator age, as indicated in Section 5.2.

The cod, haddock, whiting and mackerel data were processed using option iv. However, because the saithe samples were patchily distributed and the trawl catch rates were very variable, the data were weighted by sample size (option ii). This was the only difference between the methods used to process the five primary predators.

## 5.2 Age/length transformations

In order to provide the required input to MSVPA it was necessary to transform the original stomach contents data, which are based on the size classes of the predators and their prey, into age-based data. The basic information used to effect this transformation is given in Tables 3A-I. Most of the age/length data were collected during the quarterly research vessel surveys, using the ICES roundfish sampling areas (Figure 1) as otolith sampling strata. For saithe and sandeels, additional material was collected from the commercial fishery.

The average stomach content of a predator of a given age is estimated by calculating the weighted average of the stomach contents of all size classes occupied by that age class. The weighting factors, which are the proportional contributions of each size class to the total size distribution of the predator age class, are obtained by referring to the columns in Tables 3A-E. However, most

of the predator species also feature as prey. In this case it is necessary to determine the proportion of prey in each length class that must be assigned to each age class. These proportions can be calculated by referring to the rows in Tables 3A-E.

The conventional age/length keys of those species that featured only as prey (Norway pout, herring, sprat and sandeel) are given in Tables 3F-I. For Norway pout, herring and sprat, adequate keys for most area/quarter combinations are available. It should be noted that the ages of herring only go up to 5+, c.f. 6+ for the other prey species. This is because the computer programs developed at IJmuiden treat age groups of herring in exactly the same way as roundfish, assuming a "birthday" on 1 January. Under this convention, fish born in August 1989 (ie 1989 year class) become 1+ on 1 January 1990. North Sea herring biologist use a different convention, which does not classify these fish one-year-olds ("one-ringers") until 1 January 1991. When the data were translated into the ICES IYFS data base in IJmuiden, via an exchange tape, one age group was lost and the 6+ herring became 5+.

The age/length keys available for sandeels in 1991 are rather sparse, as in the previous North Sea stomach sampling programmes. This is regrettable. Not only are sandeels an important prey of many species of fish, as well as being the object of the largest single-species fishery in the North Sea, but also their growth rate exhibits considerable geographical variation within the North Sea. This means that a comprehensive analysis of the sandeel data requires regional and seasonal age-length keys. Unfortunately, sandeels are almost never caught in trawls during the winter, when the fish are reputed to spend most of their time buried in the sand, and even in the summer months, when the fish are feeding actively, they are seldom caught in representative numbers during routine bottom trawl surveys because they are able to pass through the meshes of most standard survey gears. However, sandeel otoliths were collected from Danish and Norwegian commercial landings in 1991, as well as on some dedicated research vessel cruises in the northwestern North Sea. Most of this material was collected in the second and third quarters. Only three roundfish areas were sampled in the first quarter, and none was sampled in the fourth quarter. Because many of the area ALKs obtained from the commercial landings were based on a large number of otoliths covering a small number of size classes and many of the research vessel ALKs consisted of a small number of otoliths distributed over a wide size range, it was decided to combine them over bigger areas. Otoliths from areas 1, 2, 3 and 7 were used to construct a "northern North Sea" key and those from areas 4, 5 and 6 contributed to a "southern North Sea" key. These keys were made by calculating the percentage age composition within each size class within each roundfish sampling area and averaging the percentages. This procedure gives equal weight to each sampled area. Fourth quarter data were processed using third quarter keys and keys for the second quarter were

used to calculate percentage age compositions of the larger size classes of sandeels in the first quarter.

The sandeel ALKs are for Raitt's sandeel (*Ammodytes marinus*), which makes up the great majority of the commercial fishery in the North Sea. Although it is likely that most of the sandeels in the stomachs of the predators were *A. marinus*, two other species (*Hyperoplus lanceolatus* and *Gymnammodytes semisquamatus*) were identified on a few occasions and the two other species of sandeel known to occur in the North Sea (*H. immaculatus* and *A. tobianus*) may have been present.

The weight of the stomach contents of an individual predator of given age, averaged over the whole North Sea, was calculated by weighting the average stomach contents in each roundfish sampling area (Figure 1) by:

- i) an estimator of predator abundance (area catch rate, Tables 1A-E), and
- ii) a factor representing the size of the area (the approximate number of statistical rectangles within the 200 m depth contour, Table 2).

## 6 Results

### 6.1 Sampling intensity

#### 6.1.1 Primary species

##### Demersal Phase

The numbers of stomachs sampled in 1981 and 1991 are compared in Table 5. More haddock, whiting, mackerel and saithe stomachs were sampled than in 1981, but slightly fewer cod. The overall increases can be attributed mainly to the introduction of additional size classes of small and medium-sized fish in 1991; considerably fewer "large" predators were sampled than in 1981 (Table 5). The numbers of stomachs in each size class sampled in each roundfish sampling area in each quarter of 1991 are given in Tables 6A-E.

The numbers of cod, haddock, whiting, mackerel and saithe stomachs sampled in each rectangle in each quarter of 1991 are given in Figures 2-6. The spatial distribution of the samples of cod, haddock and whiting was satisfactory in each quarter, thanks mainly to the participants in the International Bottom Trawl Surveys. The more patchy distribution of saithe and mackerel in the North Sea (as revealed by demersal trawling) is reflected in the distributions of the stomach samples. The younger saithe age classes (0+, 1+, 2+) are known to occur close inshore, mainly along the east coast of Britain and the Norwegian coast. Very few saithe stomachs were obtained from these inshore grounds and only saithe aged 3+ and older are included in the MSVPA.

##### Pelagic 0-Group Phase

Samples of pelagic 0-group cod, haddock, whiting, saithe and, for comparison, Norway pout were obtained from the northern North Sea in June and July and from the southeastern North Sea in June. The results given in this report (Section 6.3.2, Figs 7 and 8) relate to fish sampled east of the Shetland Islands (60°00'N 00°00'W) in June 1991.

#### 6.1.2 Other predators

The numbers of stomachs of "other" predators sampled in each quarter of 1991 are given in Table 6-F. With the exception of grey gurnard and the rays (*Raja spp.*), which have been worked up, these numbers are based on check lists sent to the Coordinator at the end of each cruise and must be regarded as preliminary estimates. Considerably more species were sampled than had been requested in the Manual. This undoubtedly reflects the enthusiasm of the sea-going participants in the project!

## 6.2 Empty stomachs

The percentages of empty stomachs in each predator size class in each quarter in each roundfish area are given in Tables 7A-E. For each of the five primary predators, the proportion of empty stomachs was highest in the first quarter of the year. In the second, third and fourth quarters, the percentages of empty stomachs were similar to, or lower than, the comparable values in 1981. However, in the first quarter the percentage of empty stomachs was higher than in 1981, for all five predators. The increase was small in the case of cod, but large for haddock, whiting, mackerel and saithe.

These results must be treated with caution. It seems highly likely that in 1991, as in the previous stomach sampling projects, difficulties were experienced in distinguishing between empty and regurgitated stomachs. There were marked between-ship differences in the proportions of grey gurnard stomachs classified as empty (de Gee and Kikkert, 1993). These differences cannot be attributed to environmental factors such as the depth and temperature of the water from which the samples were collected. It appears that different workers may have applied different criteria when classifying the stomachs. This is indeed disturbing. It is important that empty stomachs are identified correctly because the proportion of non-feeding fish in the sample has a direct bearing on the estimated mean stomach contents (Eqn 1).

## 6.3 Composition of the stomach contents

#### 6.3.1 Primary predators

##### Demersal Phase

Information on the general composition of the diet of each age class in each quarter of 1991, on a total North

Sea basis, is given in Tables 8A-E. It should be noted that the data for 0-group fish given in the main tables in this report refer only to fish caught in demersal trawls. The pelagic 0-group samples were treated separately. The tables give the percentage contribution, by weight, of each major prey taxon to the stomach contents of each predator. Species of commercial importance, including the crustaceans *Crangon crangon*, *Nephrops norvegicus* and *Pandalus* spp. are shown separately.

Most of the food of cod, whiting, mackerel and saithe of all ages consisted of crustacea and fish and the greater part of the fish eaten by these predators were species of commercial importance. The diet of haddock was more varied, and included a larger proportion of echinoderms, annelids and molluscs.

#### Pelagic 0-Group Phase

It proved difficult to describe in detail the diet of the pelagic 0-group gadoids because the stomachs were very small and much of the food was in an advanced stage of digestion. Many of the fish prey could not be identified to species level and were categorised simply as "gadoid", "flatfish" or "sandeel". Often it was only possible to class the remains as "fish" and guess the number present. The results of the analyses are summarised in Figures 7-9.

Whereas a large part of the diet of Norway pout consisted of crustacea, the other species ate considerable quantities of fish (Figure 7). Indeed, more than 70% (by weight) of the food of cod and whiting consisted of fish. Haddock and saithe contained less fish than cod and whiting, but more than Norway pout. Most of the fish that could be identified were whiting and sandeels. Cannibalism was recorded; cod were found in the stomachs of cod and it was estimated that as much as 5% of the food in the whiting stomachs was whiting. Fish were an important component in the diet of even very small fish (Figure 8). The body lengths of some of the prey eaten by cod and whiting were surprisingly large (Figure 9).

#### 6.3.2 Other predators

The only "other" predators that had been worked up completely by the end of 1996 are grey gurnard (de Gee and Kikkert, 1993) and four species of ray (Daan *et al.*, 1993). Summaries of the food of grey gurnard and starry ray *Raja radiata* (the only ray that was sampled in large numbers) are given in Tables 8F-G. These data, which are based on predator size classes, are copied directly from, (*R. radiata*) or adapted from, (*E. gurnardus*) the published reports cited above.

The diet of grey gurnard consists mainly of crustaceans and fish, fish generally predominating in medium-sized and large gurnards (> 200 mm). A large proportion of the fish prey was commercially exploited species.

The starry ray is also a fish eater. Because rays chew their food, prey items were often difficult or impossible to identify to species level. However, commercially important species were found in the stomachs.

#### 6.4 Size distribution of prey

The size distributions (percentages by number) of the prey of each size class of each predator in each quarter are given in Tables 9A-E. Fish prey and crustacean prey are presented separately. It is clear that bigger fish tend to eat bigger prey.

#### 6.5 Size composition of exploited fish prey species

The size compositions of each commercially exploited prey in the stomachs of each predator size class in each roundfish sampling area in each quarter are given in Tables 10A-E.

#### 6.6 Weights, numbers and estimated weight at ingestion of the exploited fish prey species

Tables 11-13A-E contain the main "end product" of the project, ie the feeding data used as input to MSVPA. It is important to note that these tables were prepared after modifications to the ISR software in 1995 and 1996. They differ from those supplied to the MSVPA WG in 1993 and they are not compatible with the equivalent tables for 1981 given in Daan (ed.) 1991. The major changes are described below.

Tables 11 and 12 include, respectively, the estimated weights and numbers of MSVPA prey species per thousand predator stomachs. Prior to their modification in 1996, the ISR programs extracted from the stomach contents data only those records in which the prey had been identified to species level. However, during the analysis of the stomach contents some prey were identified only to family level (eg Clupeidae, Gadidae). Records of this type were ignored by the programs. To obtain a better estimate of the contributions to the predators' diet by the MSVPA species and four commercially important species of flatfish, fish prey identified as Gadidae, Clupeidae, Pleuronectidae and Soleidae were redistributed within their family as follows:

Gadidae → Cod; haddock; Norway pout; saithe; whiting; non-commercial Gadidae

Clupeidae → Herring; sprat; non-commercial Clupeidae

Pleuronectidae → Plaice; common dab; lemon sole; non-commercial Pleuronectidae

Soleidae → Sole; non-commercial Soleidae (usually only solenette)

If the prey item (eg Clupeidae) had been assigned to a particular size class (I), the redistribution was made over

all family members in this size class (eg herring [I], sprat [I]), for weights and numbers separately:

$$\text{Her[i]} = \text{Her[i]} + \{\text{Clu[i]} * (\text{Her[i]} / (\text{Her[i]} + \text{Spr[i]}))\}$$

If the prey item was well digested and the size classified as unknown (u), it was distributed over all recorded size classes of the species in the family:

$$\text{for } I = 1 \text{ to } n: \text{Her[i]} = \text{Her[i]} + \\ \{\text{Clu[u]} * (\text{Her[i..n]} / (\text{Her[i..n]} + \text{Spr[i..n]}))\}$$

The redistribution was done for predator size classes. Prey were redistributed first at the statistical rectangle. The algorithm was then deployed at roundfish sampling level to distribute prey which could not be "matched" at rectangle level.

It should be noted that no attempt was made to redistribute prey in the category "unidentified fish". In consequence, the proportional contribution to the predators' diet by some or all of the MSVPA species will have been under-estimated to some degree.

Another modification to the programs was made in 1996 with respect to the treatment of Ammodytidae (sandeels). There are 10 NODC codes which can be applied to sandeels found in the stomachs of North Sea predators, depending on whether the prey item has been identified to the level of family, genus or species. Previous versions of the ISR programs did not search the stomach contents data sets for all of these possible records and in consequence the importance of sandeels in the diet has been underestimated in the past. The new programs extract all records of sandeels, but it should be noted that the data for Ammodytidae now include three genera (*Ammodytes*, *Hyperoplus*, *Gymnammodytes*) and at least four species. The modified programs will be used to reprocess all the pre-1991 stomach data before the next meeting of the MSVPA WG (August 1997).

The estimated mean weights at ingestion of the MSVPA fish prey (Table 13) are not directly comparable with the corresponding data for 1981 given in Daan (ed) 1989. In the first place, the 1991 data now include previously unallocated prey, as described above. In the second place, the estimation procedure has been revised. In the past, mean weights at ingestion were estimated by dividing the average weights of prey (Table 11) by the average numbers (Table 12) to calculate the mean weight of each prey in the stomach. The mean weights were then multiplied by a factor of two, on the assumption that items in the stomach were, on average, 50% digested. However, an analysis of the stomach contents data sets undertaken in 1996, in which the weights of "pristine" food items were compared with partially digested items, led to the conclusion that a multiplying factor of 1.6 should be used (ICES, 1996b). The values given in Table 13 were calculated using the new multiplying factor. It should be noted that the application of a constant multiplying factor to "raw" stomach contents data can

produce some unlikely estimates of mean weights at ingestion, particularly in cases when only a few prey items were found in the stomachs and these happened to be either virtually intact, or almost completely digested.

## 7 Summary and discussion

In many respects the 1991 stomach sampling project was an extremely successful exercise. In particular:

- Most of the sampling targets set by the Planning Group were attained or exceeded. Although fewer of the largest size classes of the predators were sampled than in 1981, this was largely a reflection of the fact that the size compositions of the predator populations had changed. Large fish were scarcer in the North Sea in 1991.
- For cod, haddock and whiting, good spatial coverage of the North Sea was achieved in each quarterly period. The less complete coverage of saithe and mackerel reflects the patchy distribution of the species.
- The analyses of the stomach contents were completed by the agreed deadline and the results were made available to the 1993 meeting of the MSVPA Working Group, as scheduled. By contrast, the results of the 1981 project were not available until 1984.
- The application of standard methods of data storage and analysis to all five primary predators ensured that the results were internally consistent.
- The sampling of additional predators in 1991 has revealed that at least two species (starry ray and grey gurnard) may be important predators of exploited species in the North Sea. Indeed, a preliminary estimate by de Gee and Kikkert (1993) indicates that grey gurnard may be consuming quantities of 0-group MSVPA species equal to or greater than those eaten by some of the primary predators included in the MSVPA.
- Examination of the stomach contents of the pelagic 0-group gadoids sampled in 1991 indicated that significant predation of MSVPA species, including cannibalism, occurs during this phase of the life history.

However, not everything went according to plan. In the first place, although the results were processed and made available to the MSVPA WG more quickly than in 1981, adherence to this rather tight schedule may be at least partly responsible for the fact that the data passed to the MSVPA WG in October 1993 contained errors.

In the second place, not all the difficulties encountered during the previous North Sea stomach sampling projects have been overcome. There are several problems that should be addressed before another large-scale stomach sampling exercise is undertaken:

- The targets set for 1991 were intended to maintain sampling at a level similar to that achieved in 1981. However, the numbers of cod, haddock and whiting stomachs sampled in 1981 considerably exceeded the numbers envisaged when the 1981 project was first discussed (a minimum of 6,000 stomachs per species). It must therefore be accepted that the targets set for 1991 were somewhat arbitrary. Although it seems inherently unlikely that too few stomachs were sampled (with the possible exception of the largest size classes) there is the very real possibility that far more stomachs were sampled than was necessary to describe adequately the diets of the predators and to satisfy the requirements of MSVPA. The planning of any future large-scale stomach sampling project should include a statistical analysis of the existing data sets with a view to devising a more rational sampling scheme.
- In spite of the guidance given in the Project Manual (ICES, 1991), it seems that it was still difficult to discriminate at sea between empty and regurgitated stomachs. There is circumstantial evidence that different sampling teams may have used different criteria.
- There are still problems in deciding what to do when "pristine" (ie completely undigested) prey are found in a stomach. This is not a trivial matter. Fresh fish prey items can be large and heavy. A single prey item of this type may have a considerable effect on the estimated stomach contents weight of a predator size class, even when the data are averaged over the total North Sea. Furthermore, because of the way in which the data are transformed from size classes to age classes, an aberrant value within one size class may effect several predator and prey age classes. The exclusion of all such prey items will result in the average stomach contents being underestimated, because some predators will have been captured almost immediately after they had taken a meal. However, some prey may have been eaten while the predators were swimming in the net (Bromley and Last, 1990). If these food items are included, the mean weight of the stomach contents will be overestimated.
- The age/size class keys for most of the prey species were of a higher quality than those available in 1981. However, the sandeel keys were still rather unsatisfactory. The reasons for this deficiency are fairly straightforward. Sandeels are rarely caught in any quantity during routine trawling surveys, because they pass through the meshes of standard trawls. In consequence, samples of sandeel otoliths have to be obtained either from the commercial fishery, which is highly seasonal and takes place on a relatively small number of fishing grounds, or from dedicated surveys, using small-meshed trawls. This problem was anticipated in the 1991 project Manual, which reminded species coordinators of the possibility of constructing age/length keys using otoliths taken from prey that were in good condition. In the event, few sandeel otoliths were collected from predator stomachs and no attempt was made to use the limited information that was available.
- No satisfactory way of estimating the mean weights of each age class of each MSVPA prey at the time of their ingestion has yet been found. It is obviously unsafe to assume that each age group of each predator can exploit the entire size range of each prey age class. Although the largest predators may be able to handle all size classes of all age classes of some prey species, the smaller, younger predators may only be able to handle the smallest individuals of some prey age classes. Therefore the mean weight at age of prey in the sea cannot be used as a proxy for the mean weight of prey eaten by the predators. As indicated in Section 6.6, the mean weights at ingestion in 1991 were calculated by multiplying the mean weights of prey in the stomachs by a constant factor (1.6). Some of these weights are unrealistic (Tables 13A-E). Another way of addressing the problem would be to calculate the mean length of each prey age class in the stomach of each predator age class and to estimate the mean weight by means of a length/weight relationship.
- During the 1989 meeting of the Planning Group it was agreed that improved models of food consumption should be developed in parallel with the 1991 stomach sampling project (ICES, 1989). However, no real progress has been made and there is still considerable uncertainty as to the daily/quarterly/annual rations consumed by individual predators.

## 8 Acknowledgements

The 1991 stomach project could not have succeeded without the cooperation and enthusiasm of the many scientists from national institutes who collected stomachs at sea. Stomach sampling was usually an additional burden imposed on a heavy existing workload and the coordinators are extremely grateful to all those who contributed their time and effort. In addition, many people participated in the analysis of the stomach contents and the computerisation of the raw data. It is not possible to acknowledge them all by name but special thanks are owed to Margaret Bell, Mette Bertelsen, Ton de Gee, Tomas Grohsler, Eilert Hermansen, Barbara Johnsson, Arjen Kikkert, Julie McMillan, Majbritt Salhaug, Mumtaz Tirasin and Bas Vingerhoed. The valuable

assistance of Henny Welleman, who in 1996 took on the job of modifying the ISR programs, also deserves special recognition. Finally, it is a pleasure to acknowledge the encouragement and support given to the project by the two most recent Chairmen of the Multispecies Assessment Working Group (Steve Murawski and Jake Rice).

## PREY OF 0-GROUP GADOIDS IN THE NORTHERN NORTH SEA IN JUNE 1991

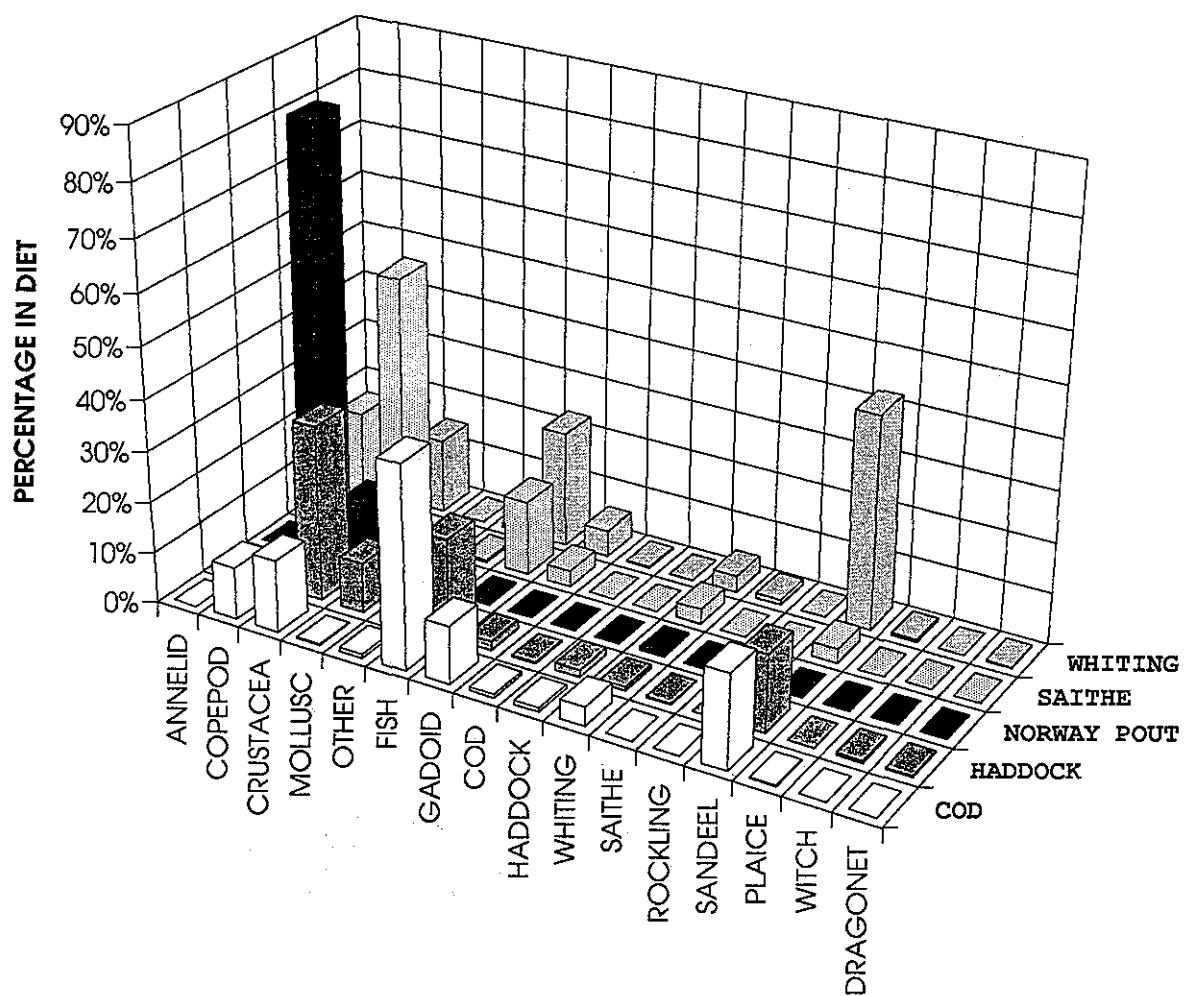

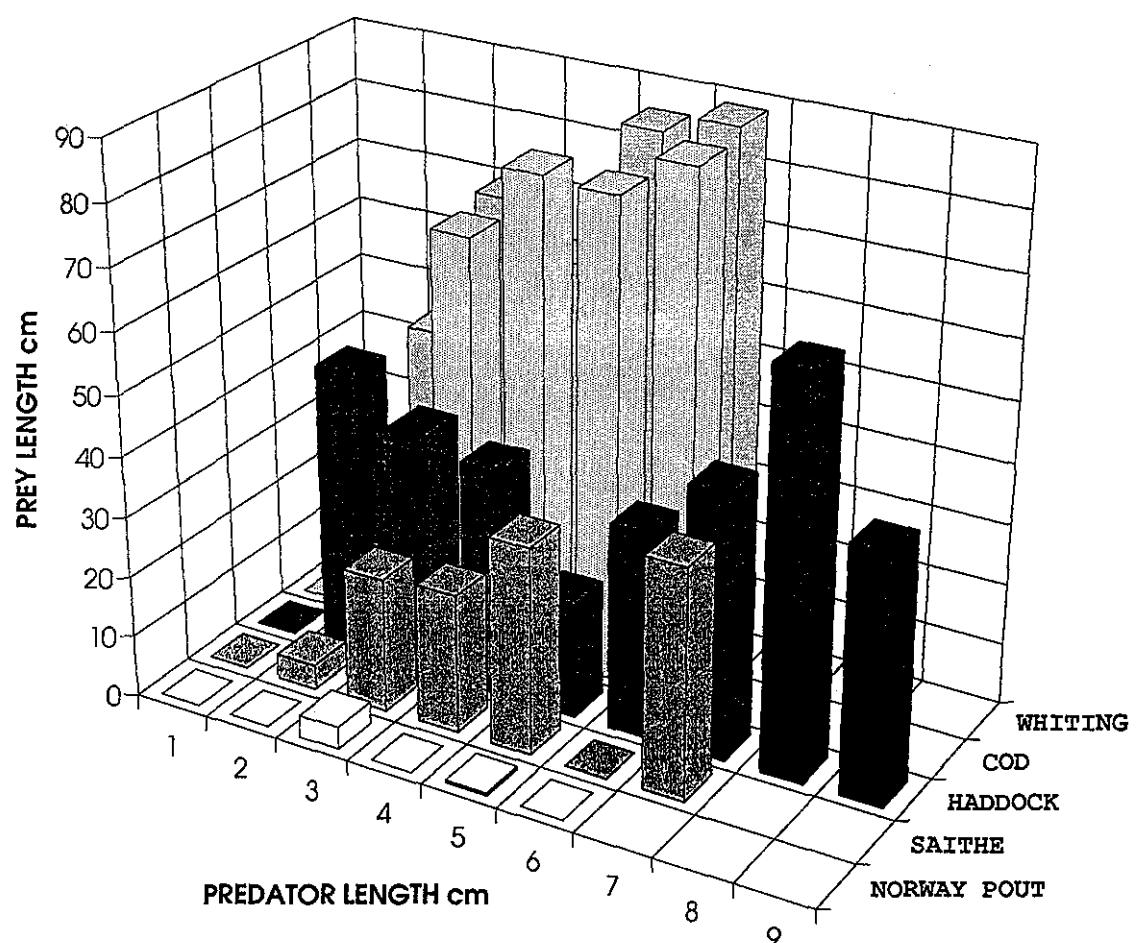

FIGURE 7      Stomach contents (percentage by weight) of 0-group gadoids in the northern North Sea in June 1991.

**PERCENTAGE OF FISH PREY IN THE DIET OF 0-GROUP GADOIDS IN THE NORTHERN NORTH SEA IN JUNE 1991**

**FIGURE 8** Percentage by weight of fish prey in the diet of 0-group gadoids in the northern North Sea in June 1991.

### LENGTH OF FISH PREY IN RELATION TO LENGTH OF PREDATOR

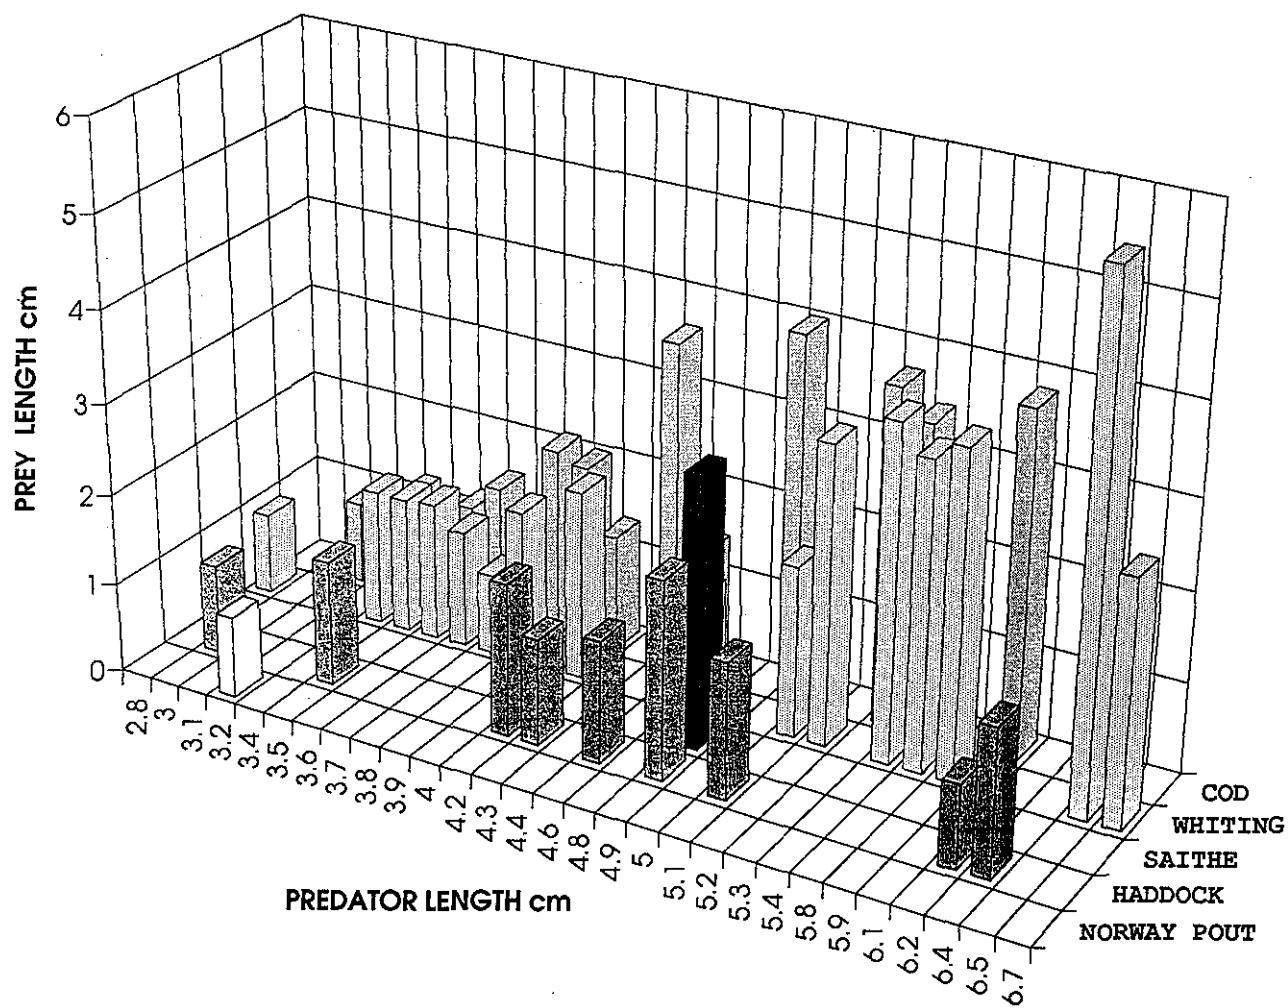

FIGURE 9 Length of fish prey in the stomachs of 0-group gadoids of each size sampled in the northern North Sea in June 1991.

## Appendix A

Numbers of non-regurgitated stomachs that were to be collected per size class per haul in each quarter of 1991

Size class (cm)	Species									
	Primary predators					Secondary predators				
	Cod	Whiting	Saithe	Mackerel	Haddock	Sead	Gurnards*	Rays*	LR dab	Other*
5-5.9	5	5	5	5	5					
6-6.9	5	5	5	5	5					
7-7.9	5	5	5	5	5					
8-9.9	5	5	5	5	5					
10-11.9	5	5	5	5	5					
12-14.9	5	5	5	5	5					
15-19.9	10	10	25	25	5	10	10	10		
20-24.9	10	10	25	25	5	10	10	10	10	
25-29.9	10	10	25	25	5	10	10	10	10	
30-34.9	10	10	25	25	5	10	10	10	10	
35-39.9	10	10	25	25	5	10	10	10		
40-49.9	10	10	25	25	5	10	10	10		
50-59.9	10	10	25		5			10		
60-69.9	25	10	25		5			10		
70-79.9	25		25		5			10		
80-99.9	25		25					10		
100-119.9	25		25					10		
>120	25		25					10		

\*Each species of gurnard and ray was sampled separately

\*The following demersal species normally occur infrequently but were sampled whenever possible (up to five stomachs per size class):

Tope	<i>Galeorhinus galeus</i>
Spurdog	<i>Squalus acanthias</i>
Spotted dogfish	<i>Scyliorhinus caniculus</i>
Conger	<i>Conger conger</i>
Pollack	<i>Pollachius pollachius</i>
Ling	<i>Molva molva</i>
Torsk	<i>Brosme brosme</i>
Hake	<i>Merluccius merluccius</i>
Angler fish	<i>Lophius piscatorius</i>
Turbot	<i>Scophthalmus maximus</i>
Brill	<i>S. rhombus</i>
Megrim	<i>Lepidorhombus whiffiagonis</i>
Halibut	<i>Hippoglossus hippoglossus</i>

In the case of pelagic 0-group gadoids and greater sandeel (*Hyperoplus*) a random sample of 50-100 individuals per haul was required.

## Appendix B

Format for North Sea stomach data exchange tape.

Position	Name	Type <sup>a</sup>	Range of values	Comment
1-2	Ecosystem name	2N	1-8	Footnote <sup>b</sup> for coding scheme
