## Atlantic salmon (Salmo salar) in subdivisions 22-31 (Baltic Sea, excluding the Gulf of Finland)

## ICES stock advice

ICES advises that when the maximum sustainable yield (MSY) approach is applied, total commercial sea catch in 2018 should not exceed 116000 salmon. Applying the same catch proportions estimated from observations in the 2016 fishery, this catch would be split as follows: $9 \%$ unwanted catch (previously referred to as discards) and $91 \%$ wanted catch ( $68 \%$ reported, $7 \%$ unreported, and $16 \%$ misreported).

ICES advises that management of salmon fisheries should be based on the status of individual river stocks. Fisheries on mixed stocks that cannot target only river stocks with a healthy status, present particular threats to stocks that do not have a healthy status. Fisheries in open-sea areas or coastal waters are more likely to pose a threat to depleted stocks than fisheries in estuaries and rivers. Effort in these mixed-stock fisheries has been reduced to low levels and should not increase.

The salmon stocks of rivers Rickleån, Kågeälven, and Testeboån in the Gulf of Bothnia, Emån in southern Sweden, and several rivers in the southeastern Main Basin are especially weak. These stocks need longer-term, stock-specific rebuilding measures, including fisheries restrictions in estuaries and rivers, habitat restoration, and removal of physical barriers. In order to maximize the potential recovery of these stocks, exploitation should not increase along their feeding and spawning migration routes at sea. The offshore fishery in the Main Basin catches all weak salmon stocks on their feeding migration. The coastal fishery catches weak stocks from northern rivers when the salmon pass the Åland Sea and the Gulf of Bothnia on their spawning migration.

## Stock development over time

To evaluate the status of wild stocks, ICES uses smolt production relative to the potential smolt production capacity (PSPC) on a river-by-river basis. Time-series indicate that the status for most stocks has improved over the last five years. The number of rivers where smolt production has reached $50 \%$ and $75 \%$ of the PSPC with a probability of $>70 \%$ has increased (Table 9) compared to the last analytical assessment in 2015. Of the 29 rivers assessed in subdivisions 22-31:

- the probability that smolt production in 2016 reached $50 \%$ of the PSPC is above $70 \%$ for 18 rivers, between $30 \%$ and $70 \%$ for three rivers, and below $30 \%$ for eight rivers.
- the probability that smolt production reached $75 \%$ of PSPC in 2016 is above $70 \%$ for 14 rivers.

With a few exceptions, the rivers in the northern Baltic Sea area present a better status than the southern ones.
The 2017 assessment indicates that total wild smolt production has increased tenfold in assessment units (AUs) 1-2 since the Salmon Action Plan (ICES, 2008a) was adopted in 1997 (Figure 2a). Smolt production in AU 3, however, only shows a weak positive trend, while it has remained at around the same level in AU 4. Despite the overall increase in wild smolt production, the decline in post-smolt survival (Figure 3) from the late 1980s until the mid-2000s has impacted fishing opportunities. Post-smolt survival has improved slightly since 2005 and appears to have remained stable in recent years.

Smolt production estimates for AU 5 rivers are based on parr density data in combination with expert judgement about mortality rates. Smolt production in AU 5 has been low for many years (Figure 2a), but in 2015 and 2016 it increased in several rivers and, based on parr density data, may be expected to increase in the near future.

The harvest rate of salmon has decreased considerably since the beginning of the 1990s (Figure 2b). The overall trend in the status of the pre-fishery stock abundance is estimated to have remained largely unchanged over the last few years (Figure 2c).

Figure 1 Salmon in subdivisions 22-31 (Main Basin and Gulf of Bothnia). Total removals (dead catch) in numbers in the years 1987-2016: river catches (mainly recreational, but including also some commercial fishing) and removals at sea (split into commercial and recreational nominal landings, unreported and misreported landings, and dead discards). Commercial sea catch also includes recreational sea catch in 1987-2000.

Figure 2a
Salmon in subdivisions 22-31 (Main Basin and Gulf of Bothnia). Top and middle rows: Smolt production (time-series) and PSPC (horizontal solid line) for AUs 1-4 (median estimate for the entire unit and $90 \%$ probability intervals). Bottom: Smolt production relative to PSPC for AU 5 (median estimate across the wild rivers and $90 \%$ probability interval).

Figure 2b Salmon in subdivisions 22-31 (Main Basin and Gulf of Bothnia). Harvest rates in offshore (by fishing season; left) and coastal (by calendar year; right) fisheries.

Figure 2c Salmon in subdivisions 22-31 (Main Basin and Gulf of Bothnia). Estimated pre-fishery abundance in the sea (PFA; wild and reared, 1SW and MSW fish in total) for scenario 1 (Table 1). The median estimate and $90 \%$ probability intervals are plotted, diamond symbols indicate projections from the model.

## Catch options

Five fishing scenarios were considered for 2018 (Table 1). Scenario 1 corresponds to the total commercial catch at sea advised by ICES for 2014-2017 (116 000 salmon per annum). Scenarios 2 and 3 represent a $20 \%$ increase and a $20 \%$ decrease in catch, respectively, compared with scenario 1. Scenario 4 follows the EU Commission's proposal for a multiannual plan for Baltic salmon (EC, 2011). Two options are presented under scenario 4: (a) $\mathrm{F}=0.1$ covers the commercial catch at sea; (b) $\mathrm{F}=0.1$ covers total (commercial and recreational) catch at sea. Both of these options, scenarios 4(a) and 4(b), are calculated based on estimates of pre-fishery abundance (PFA) at the beginning of 2018. Scenario 5 illustrates stock development under no fishing, neither at sea nor in rivers.

The outlook table for 2018 (Table 1) splits the total commercial catch at sea into similar components as in previous years, using the proportions estimated to have occurred in 2016: wanted catch reported (67.5\%), wanted catch unreported ( $7.0 \%$ ), wanted catch misreported ( $16.2 \%$ ), and unwanted catch ( $9.3 \%$; this is the catch that would be discarded if discarding was allowed). The $9.3 \%$ unwanted catch is the sum of $2.6 \%$ (undersized salmon) and $6.6 \%$ (seal-damaged salmon). Seal-damaged salmon are always dead, whereas some of the undersized salmon would survive if they were discarded. All scenarios assume additional recreational catches at sea that constitute $16.8 \%$ of the total (commercial + recreational) sea catch, based on the available data for 2016, and a constant harvest rate in rivers on returning salmon.

Table 1 Salmon in subdivisions 22-31 (Main Basin and Gulf of Bothnia). The catch options for 2018.

| Scenario | Commercial catch at sea in subdvisions 22-31 in 2018 |  |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  | Total commercial catch at sea | Wanted catch Reported | Unwanted catch (dead + alive) |  | Wanted catch Unreported | Wanted catch Misreported |
|  |  |  | Undersized | Seal damaged |  |  |
| 1 | 116.0 | 78.4 | 3.1 | 7.7 | 8.1 | 18.8 |
| 2 | 139.2 | 94.0 | 3.7 | 9.2 | 9.7 | 22.6 |
| 3 | 92.8 | 62.7 | 2.5 | 6.1 | 6.5 | 15.1 |
| 4(a) | 139.1 | 94.0 | 3.7 | 9.2 | 9.7 | 22.6 |
| 4(b) | 115.8 | 78.2 | 3.1 | 7.7 | 8.1 | 18.8 |
| 5 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 |
| Scenario | Recreational catch at sea 2018 | Total sea catch (comm. <br> + recr.) 2018 | River $201$ |  |  |  |
| 1 | 23.4 | 139.4 |  | 52.0 |  |  |
| 2 | 28.1 | 167.3 |  | 49.0 |  |  |
| 3 | 18.7 | 111.5 |  | 55.0 |  |  |
| 4(a) | 28.1 | 167.2 |  | 49.0 |  |  |
| 4(b) | 23.4 | 139.1 |  | 52.0 |  |  |
| 5 | 0.0 | 0.0 |  | 0.0 |  |  |

All values in the table are in thousands of fish.
Note: The figures in the table are rounded. Calculations were done with unrounded inputs and computed values may not match exactly when calculated using the rounded figures in the table.

## MSY approach

Figures 5a-b present the river-specific annual probabilities of meeting $75 \%$ of the PSPC under each scenario for the 16 wild rivers of AUs 1-4 included in the stock projections. Table 10 shows these probabilities for year 2023 (for stocks in AUs 1-3) or 2022 (for stocks in AU 4), which is approximately one full generation ahead from now. The results indicate relatively small differences between scenarios 1-4; only scenario 5 (zero fishing) is clearly different. There are, however, differences between rivers, with some of them having a much lower probability of reaching $75 \%$ of the PSPC. Rivers Emån (southern Sweden) and Simojoki and Rickleån (Gulf of Bothnia) have the lowest probabilities, though Rickleån shows positive trends under most scenarios.

Figure $6 \mathrm{a}-\mathrm{b}$ displays estimated smolt production in the past and projected future smolt production under scenario 1. For all rivers except Emån and Mörrumsån, smolt production in 2022-2023 is expected to remain around current levels or to increase.

The status of the stock, based on the PFA abundance, is estimated to have remained largely unchanged, and the commercial catch at sea advised last year (scenario 1 in the catch options) is considered to provide the upper limit for exploitation under the MSY approach. This would imply a total commercial sea catch not exceeding 116000 salmon in 2018.

Stock projections have not been conducted for Testeboån (AU 3) and for stocks in AU 5. Although a few rivers in AU 5 have shown signs of recovery in 2015 and 2016, the majority of these stocks are still regarded as weak. Mixed-stock fisheries pose a special problem in the fisheries management for these stocks. Effort in the fisheries has been reduced to low levels in recent years and should not increase. The reasons for the low productivity of southern stocks is not entirely clear but may, at least partly, be caused by conditions in the freshwater environment (ICES, 2014, 2015). Special actions (not only fishery-related) for these stocks are required in addition to the TAC.

## Management plan

According to the management plan proposed by the EC "the annual TAC for salmon stocks at sea shall not exceed the level corresponding to a fishing mortality rate of 0.1 ". It is further stated that "the TAC will only cover marine fisheries but will include masters of non-fishing vessels offering services for recreational fisheries" (EC, 2011). The plan does not specify exactly how to interpret $\mathrm{F}=0.1$, or whether this value covers the total catch at sea or only the commercial part of this catch. Different fisheries occur at different points in time and space, and many fisheries catch only maturing salmon.

Hence, any catch calculation based on $F=0.1$ is only approximate. ICES calculated the 2018 catch option by calculating the abundance at sea on September 1st for 1-sea-winter (1SW) fish and on July 1st for multi-sea-winter (MSW) fish, accounting for natural mortality from the start of the year, and then applying the exploitation rate.

If $F=0.1$ covers only the commercial catch at sea (scenario 4(a)), this corresponds to a total commercial catch at sea not exceeding 139128 salmon in 2018.

If, however, $F=0.1$ covers the total catch at sea (scenario $4(b)$ ), this corresponds to a total commercial catch at sea not exceeding 115754 salmon in 2018.

ICES has not evaluated the proposed EC management plan for consistency with the precautionary approach and MSY.

## Basis of the advice

Table 2 Salmon in subdivisions 22-31 (Main Basin and Gulf of Bothnia). The basis of the advice.

| Advice basis | MSY approach |
| :--- | :--- |
| Management plan | EC proposal (EC, 2011), not formally adopted. |

## Quality of the assessment

The assessment model could not be run with the addition of the 2016 data. The reasons remain unexplained, and ICES is currently exploring modelling options. The present assessment was therefore made using the same assessment model as previously, with data up to and including 2015. However, the predictions for 2016 from the model and the available observations for 2016 were in agreement with the assessment (ICES, 2017a). Because the most recent data (2016) could not be included in the model, the evaluation of the current status of the stocks and the stock projections are considered to be more uncertain.

The assessment produced somewhat higher estimates of pre-fishery abundance (PFA) in the sea than in the previous assessment (2015), particularly for future predictions, but with high uncertainty (Figure 7).

A benchmark process (WKBaltSalmon; ICES, 2017b) was held in 2016-2017 to evaluate available data and develop the assessment methods for Baltic salmon. Needs for improvement regarding data and methods identified during WKBaltSalmon have not yet been taken into consideration in the assessment.

The status assessment for a few river stocks (Piteälven, Öreälven, Lögdeälven, Emån, and Mörrumsån) should be regarded as uncertain, as basic input data for these rivers (river production area, potential smolt production capacity and/or smolt production priors) that were updated during WKBaltSalmon have not been included in the present assessment (ICES, 2017a, 2017b).

There are indications of currently increasing M74 mortality, as well as reported deaths of spawners due to disease problems, which may affect the projection. This extra mortality could reduce smolt production and PFA beyond the advice year, though the likely impacts are uncertain. The present advice has not taken into account a potential further increase in M74 mortality.

New data indicate that the recreational trolling catch estimates are underestimated (ICES, 2017a). Work is ongoing to refine these estimates, though the new estimates have not yet been included in the assessment.

There is considerable uncertainty about the amount of salmon discarded, and even greater uncertainty about the proportion that survives when discarded. Seal-damaged salmon are all dead, but there is also uncertainty on the amount of seal-damaged salmon. The values used in this advice represent the current available knowledge and are based on data from a variety of sources (such as logbooks, interviews with fishers, agreed sampling schemes with skippers, or Data Collection Framework (DCF) sampling data), but these data are generally sparse. Expert judgement has been applied when no data are available, or to supplement the sparse data. Because of this uncertainty, current estimates of discards should be considered only as an order of magnitude and not as precise estimates.

## Issues relevant for the advice

Salmon harvest rates are lower than experienced in the past and as such fishing mortality, as a proportion of total mortality, is lower now than in the past (Figure 2 b ). This implies that natural processes, mainly post-smolt and adult natural mortalities, currently have a higher relative impact than fishing mortality on the chances of reaching the management objective.

Fisheries on mixed stocks that cannot exclusively target river stocks with a healthy status, present particular threats to stocks that do not have a healthy status. Fisheries in open-sea areas or coastal waters are more likely to pose a threat to depleted stocks than fisheries in estuaries and rivers.

Exploitation in the Main Basin offshore fisheries affects possibilities for recovery of the Gulf of Finland salmon stocks as Gulf of Finland salmon is partly caught in the Main Basin.

A range of problems in the freshwater environment play a significant role in explaining the poor status of stocks in the southern Baltic rivers (ICES, 2012a, 2014).

Recent efforts to re-establish self-sustaining salmon stocks in "potential" rivers, where salmon stocks have been extirpated in the past, present exceptional challenges to management. The numbers of spawners in the "potential" rivers are likely to be particularly low following initial reintroductions, and productivity is likely to be lower than average. The considerations presented in this advice for the existing weak salmon stocks (e.g. habitat restorations, fishery restrictions, etc.) also apply to re-established stocks.

## Reference points

To evaluate the state of the stock, ICES uses the smolt production relative to $50 \%$ and $75 \%$ of the natural production capacity (potential smolt production capacity; PSPC) on a river-by-river basis. $75 \%$ of the PSPC reference is based on the MSY approach (ICES, 2008a, 2008b), whereas $50 \%$ of the PSPC has no formal status as a reference point in ICES but is widely considered an interim objective for weak stocks. The $50 \%$ objective is therefore also included as part of the stock status evaluation.

## Basis of the assessment

ICES uses five assessment units for salmon in the Baltic Main Basin and the Gulf of Bothnia (Figure 8). The division of stocks into units is based on biological and genetic characteristics. Stocks of a particular unit are assumed to exhibit similar migration patterns. It can therefore be assumed that they are subject to the same fisheries, experience the same exploitation rates, and could be managed in the same way (e.g. using coastal management measures might improve the status of all stocks in a specific assessment unit). Even though stocks of AUs $1-3$ have the highest current smolt productions and, therefore, have an important role in sustaining economically viable fisheries, the stocks in AUs 4 and 5 contain a relatively high proportion of the overall genetic variability of Baltic salmon stocks.

Table 3 Salmon in subdivisions 22-31 (Main Basin and Gulf of Bothnia). Assessment areas.

| Assessment unit | Name | Salmon rivers included |
| :---: | :--- | :--- |
| 1 | Northeastern Bothnian Bay stocks | On the Finnish-Swedish coast from Perhonjoki northward to the <br> river Råneälven, including River Tornionjoki. |
| 2 | Western Bothnian Bay stocks | On the Swedish coast between Lögdeälven and Luleälven. |
| 3 | Bothnian Sea stocks | On the Swedish coast from Dalälven northward to Gideälven and on <br> the Finnish coast from Paimionjoki northwards to Kyrönjoki. |
| 4 | Western Main Basin stocks | Rivers on the Swedish coast in ICES subdivisions 25-29. |
| 5 | Eastern Main Basin stocks | Estonian, Latvian, Lithuanian, and Polish rivers. |

Table 4 Salmon in subdivisions 22-31 (Main Basin and Gulf of Bothnia). The basis of the assessment.

| ICES stock data category | 1 (ICES, 2016) |
| :--- | :--- |
| Assessment type | Bayesian state-space model for a majority of rivers in AUs 1-4; assessment by expert <br> judgement for AU 5. Uncertainties about estimated quantities from the Bayesian model are <br> expressed as probability distributions. |
| Input data | Commercial removals (international landings and effort by fishery (1987-2015), wild and reared <br> proportions, tag returns); recreational catch; estimated unreported and misreported catch; <br> spawner counts in some rivers, parr densities from all rivers, smolt counts in some rivers. |
| Discards and bycatch | Included in the assessment (estimates based partly on data and partly on expert evaluation). |
| Indicators | None |
| Other information | The assessment is based on the benchmark in 2012 (IBP Salmon; ICES, 2012b). The data and <br> model options were re-examined in 2017 (WKBaltSalmon; ICES, 2017b), but more work is <br> required to update the assessment approach. |
| Working group | Assessment Working Group on Baltic Salmon and Trout (WGBAST) |

The PSPC is estimated based on a combination of expert knowledge and spawner/smolt estimates (based on river-specific stock-recruit relationships) which are derived by fitting the assessment model to the data. The assessment model updates the estimates of smolt production historically and the PSPC for each river.

## Information from stakeholders

There is no available information.

## History of the advice, catch, and management

Table 5 Salmon in subdivisions 22-31 (Main Basin and Gulf of Bothnia). ICES advice for salmon, landings, total catches, and agreed TACs; all numbers in thousands of fish. Landings and total catch figures for 2016 are preliminary.

| Year | ICES advice | Predicted catch corresponding to advice | TAC | Landings at sea^ | Catch at sea^^ | River catch |

*For comparison with TAC (includes only commercial catches, except for the years 1993-2000 when also recreational catches at sea are included).
**Preliminary.

Table 8 Salmon in subdivisions 22-31 (Main Basin and Gulf of Bothnia). The table shows total catches (from sea, coast, and river) of salmon, in numbers, in the whole Baltic (subdivisions 22-32), split into: nominal catches by country, discards (including seal-damaged salmon), and unreported catches (PI = probability interval = 90\% since $2001=$ $95 \%$ before then). Discards and unreported catches for the years 2001-2016 are estimated by a different method than for the years 1993-2000. Catch figures for 2016 are preliminary.

The data for 1993-1994 include subdivisions 24-32; the catches in subdivisions 22-23 are normally less than one tonnes. From 1995 data include subdivisions 22-32.
Catches from the recreational fishery are included in reported catches for Finland, Sweden (all years), and Denmark (only since 1998). Other countries have no, or very low recreational catches.

* In 1993 the Faroe Islands caught 3200 individuals, which is included in the total Danish catches.
** Corresponds only to Polish catch.
*** Including also the estimated misreported catch.

## Summary of the assessment

Table 9 Salmon in subdivisions 22-31 (Main Basin and Gulf of Bothnia). Overview of the status of the Gulf of Bothnia and Main Basin stocks in terms of their probability of having reached $50 \%$ and $75 \%$ of the potential smolt production capacity in 2016. The probability values are classified in four groups: Above 90\% (V.likely), between 70\% and 90\% (Likely), between $30 \%$ and $70 \%$ (Uncert.), and below $30 \%$ (Unlikely). For stocks in AUs 1-4 (except Testeboån) the results are based on the assessment conducted in 2017. Results for Testeboån and AU 5 stocks are based on expert judgement and no precise probabilities can be presented for these stocks.

MSW wild \& reared, scen 1

Figure 4 Salmon in subdivisions 22-31 (Main Basin and Gulf of Bothnia). Top panels: Annual abundances of 1-sea-winter salmon (1SW) available to the fisheries. Four months of adult natural mortality are taken into account (from 1 May until 1 September) to cover natural mortality during the fishing season after the post-smolt mortality phase. Bottom panels: Annual abundances of multi-sea-winter salmon (MSW) available to the fisheries. Six months of adult natural mortality are taken into account (from 1 January until 1 July) to cover natural mortality during the fishing season. The left panels are for wild salmon and the right panels for wild and reared salmon together. The predicted development in abundance following projection scenario 1 is also indicated.

Figure 7 Salmon in subdivisions 22-31 (Main Basin and Gulf of Bothnia). Estimated pre-fishery abundance in the sea (PFA; wild and reared, 1SW and MSW fish in total) for scenario 1 in the current (2017, data up to 2015; black) and previous (2015, data up to 2014; green) assessment, respectively. The median estimate and $90 \%$ probability intervals are plotted, hollow points with dashed tick marks indicate projections from the model.

Figure 8
Salmon in subdivisions 22-31 (Main Basin and Gulf of Bothnia). Grouping of salmon stocks in six assessment units in the Baltic Sea. The genetic variability between stocks of an assessment unit is smaller than the genetic variability between stocks of different units. In addition, the stocks of a particular unit exhibit similar migration patterns.
