

Norway lobster (Nephrops norvegicus) in Division 4.a, Functional Unit 10 (northern North Sea, Noup)

ICES advice on fishing opportunities

ICES advises that when the precautionary approach is applied, catches in each of the years 2021 and 2022 should not exceed 46 tonnes, assuming recent discard rates.

To ensure the stock in Functional Unit (FU) 10 is exploited sustainably, management should be implemented at the functional unit level.

Note: This advice sheet is abbreviated due to the COVID-19 disruption. The previous advice issued for 2019 and 2020 is attached as Annex 1.

Catch scenarios

The ICES framework for category 4 Norway lobster stocks was applied (ICES, 2012). In the absence of a full analytical assessment, ICES bases its advice for Norway lobster on the most recent advice. Maximum sustainable yield (MSY) harvest rates estimated for other FUs vary between 7.5% and 16%. ICES uses the lower boundary as an upper limit for advice for data-limited Norway lobster stocks. As long as the harvest rate is less than 7.5%, the default basis for advice is that catches can be increased gradually by applying the 20% uncertainty cap to the previous advice. The precautionary buffer has not been applied previously. Stock size in relation to reference points is unknown and has not increased significantly. Therefore, the precautionary buffer has been applied this year.

Norway lobster (Nephrops norvegicus) in Division 4.a, Functional Unit 10 (northern North Sea, Noup)

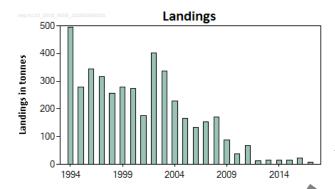

ICES advice on fishing opportunities

ICES advises that when the precautionary approach is applied, catches in each of the years 2019 an 2020 s, ould not exceed 48 tonnes.

To ensure the stock in Functional Unit (FU) 10 is exploited sustainably, management should be impresented at the functional unit level.

Stock development over time

Underwater TV (UWTV) surveys in Functional Unit (FU) 10 have been conducted sporadically any have indicated that the density is relatively low (0.13 *Nephrops* m⁻²). Landings are at a historical minimum.

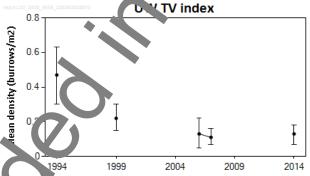

Figure 1 Norway lobster in Division 4.a, FU 10. Landing. and seems density. Error bars indicate 95% confidence intervals.

Stock and exploitation status

ICES cannot assess the stock and exploitation status elative to maximum sustainable yield (MSY) and precautionary approach (PA) reference points because the effect of points are undefined.

Table 1 Norway lobster in Division ...a, 11 10. State of the stock and fishery relative to reference points.

Catch scenar is

The ICL frame, rk for category 4 Norway lobster stocks (ICES, 2012) was applied for this stock. As the first step, the same adver as given in 2016 corresponds to a potential harvest rate of 3.0%, based on the 2014 density estimate of 0.13 Norway longter m⁻². As the stock appears to be very lightly exploited, the advice may be increased to a level corresponding to an acceptable harvest rate (HR), applying an uncertainty cap to restrict annual change to no more than 20%. The same advice as given in 2016 + 20% corresponds to a potential HR of 3.5%. This is well below the range of MSY harvest rates in the North Sea (between 7.5% and 16%), which is considered conservative. Assuming that discard rates do

ICES Advice 2018

not change from the rate of 11.9% (by number estimate for FU 9) and that the discard mortality rate is 100%, this implies catches of no more than 48 tonnes.

Table 2 Norway lobster in Division 4.a, FU 10. The basis for the catch scenarios.

	Maximum landings	520	494	26	38.5%	1200%

^{*} Wanted" and "unwanted" catch are used to described Norway lobste that would be landed and discarded, based on discard rates estimates for the average of (2015–2017).

Basis of the advice

Table 4 Norway lobster in Division 4.a, FU 10 The basis of the advice.

Advice basis	ICES precautionary ap roach
Management plan	The EU MAP for the No. th Sea is currently being finalized and is not yet adopted. For this stock it is not possible to estimate F _{MSY} ranges, therefore ICES continues to give advice based on the ICES precautionary approach

Quality of the assessment

The time-series of UWTV survey is to is incomplete, and the last survey was conducted in 2014. There are no reliable effort data for this FU and there for an resulting landings per unit of effort (LPUE).

There is no recent discard information for this fishery. Discard percentages and mean weights have been taken from the closest inshore functional init (1 U 9). The catch options are based on a calculation of potential landing options and harvest rates, given the kill will surface area of Norway lobster habitat and observed densities of the functional unit.

Issues relevant for the dvice

MSY harvest letes estimated for other FUs vary between 7.5% and 16%. Because this is a data-limited stock, ICES uses the lower bound and fithat range as an upper limit for advice.

The Norval lobster fishery at the Noup is fished by only a few vessels that visit the ground occasionally, and landings constituted less than 1% of the North Sea total. In recent years most Norway lobster landings from Noup were made by TR1 vessels targeting whitefish.

There is no discard information for this fishery. The advice is based on an assumed discard rate borrowed from FU 9.

^{**} Calculated for dead removals and applied to total catch.

^{***} Total catch 2019 & 2020 relative to advice value for 201 & 20. 3 (40

Mixed-fisheries considerations

Results from a North Sea mixed-fisheries analysis are presented in the ICES mixed-fisheries advice (ICES, 2018a). The analysis has been updated, taking into account latest changes made to the assessments and forecasts for stocks with reopened advice.

After years of positive development, North Sea cod is again estimated to be the most limiting stock in the Grea er North Sea mixed-fisheries model. For 2019, assuming a strictly implemented discard ban (correspond to the Minimum" scenario), cod is estimated to constrain 24 out of 40 fleet segments. Whiting is the second most limiting stock, constraining twelve fleet segments. Conversely, in the "Maximum" scenario, saithe and both plant stocks (North Sea and eastern English Channel) plaice would be the least limiting for 17, 9, and 3 fleet segments, it spective v. Finally, if Norway lobster were managed by separate TACs, Norway lobster in FU 7 would be the least limiting for seven fleet segments (ICES, 2018b). Norway lobster in FU 10 is not limiting in mixed-fisheries scenarios (ICES 2018).

For those demersal fish stocks for which the F_{MSY} range is available, a "range" scenario is p cented that minimizes the potential for TAC mismatches in 2019 within the F_{MSY} range. Currently, these range scenarios do not take into account Norway lobster stocks.

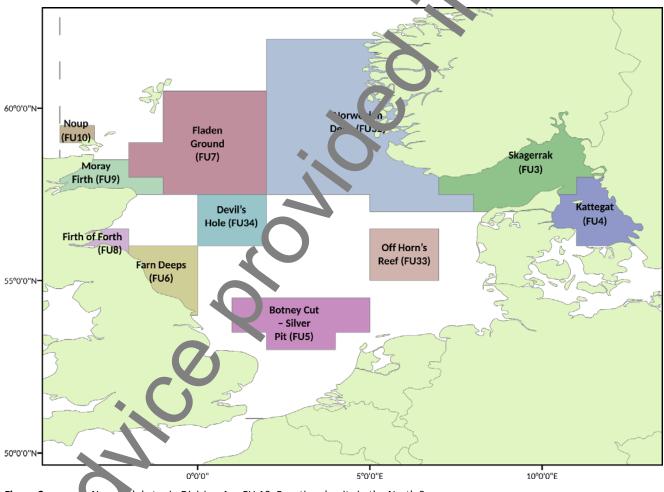

Figure 3 Norw y lobster in Division 4.a, FU 10. Functional units in the North Sea.

Refere ce p ..

No reference points are defined for this stock.
