Executive summary

The Working Group on Beam Trawl Surveys (WGBEAM) met on 10–13 April 2018 in IJmuiden, The Netherlands. The meeting was attended by 11 people representing seven countries and the ICES Data Centre, and was chaired by Holger Haslob, Germany. Data from eleven offshore and four inshore surveys were discussed (all surveys under WGBEAM coordination).

WGBEAM 2018 collated an overview of the 2017 results and the 2018 planning of all surveys under its coordination, and provided standard output under the form of updated abundance index time-series for sole and plaice in the offshore and inshore beam trawl surveys. The annual output on spatial sampling coverage of the offshore and inshore beam trawl surveys was updated.

In relation to the ICES Database on Trawl Surveys (DATRAS), actions leading to better data quality were formulated, and ongoing and future development issues were reported and/or discussed. WGBEAM reported back to the DATRAS governance group on which variables should be additionally included into the DATRAS format with regard to beam trawl surveys.

The finalization of the Offshore Beam Trawl Survey Manual was discussed and further actions taken. It was concluded that more information on the survey design should be implemented for each beam trawl survey and the draft manual should be restructured before submitting the final draft for external review.

During the meeting, WGBEAM collated information on marine spatial planning with specific attention to the construction of offshore wind farms and possible impacts on the existing surveys.

The working group discussed the progress of automating the index calculation procedure and the adoption of a modelling approach that combines several surveys into a single index based on DATRAS data (e.g. North Sea plaice and dab). However, WGBEAM indicated that the communication between survey and assessment groups is not fluent in many cases and the automation of procedures poses further risks to reducing the important communication between working groups. WGBEAM recommends that further consideration is needed by ACOM to ensure the quality of index information is maintained or improved, while it acknowledges the need for transparency, desire for consistency, and efficiency that the automation of survey indices provides. Based on this discussion WGBEAM aims to organize a two-day workshop bringing together expertise from survey and assessment groups in order to evaluate the use of the new combined indices.

WGBEAM – Working Group on Beam Trawl Surveys

2016/MA2/SSGIEOM11 The **Working Group on Beam Trawl Surveys** (WGBEAM), chaired by Holger Haslob, Germany, will work on ToRs and generate deliverables as listed in the Table below.

	MEETING DATES	VENUE	REPORTING DETAILS	COMMENTS (CHANGE IN CHAIR, ETC.)
Year 2017	4-7 April	Galway, Ireland	Interim report by 1 June 2017 to ACOM-SCICOM	New chair
Year 2018	10-13 April	IJmuiden, The Netherlands	Interim report by 25 May 2018 to ACOM-SCICOM	
Year 2019	1-5 April	ICES HQ, Copenhagen, Denmark	Final report by 17 May 2019 to ACOM-SCICOM	

ToR descriptors

TOR	DESCRIPTION	BACKGROUND	Science Plan codes	DURATION	EXPECTED DELIVERABLES
a	Tabulate, report and evaluate population abundance indices by age-group for sole, plaice and dab and other species if required in the North Sea, Division VIIa, Divisions VIId-g, Divisions VIIIab and the Adriatic taking into account the key issues involved in the index calculation.	a) Science Requirements Length-at-age analysis b) Advisory Requirements Required to support indices for assessments c) Requirements from other EGs Specific questions from other EGs possible	3.2	Annually	WG report chapter
b	Further coordinate and standardize offshore and coastal beam trawl surveys in the North Sea and Divisions VIIa, VIId-g, VIIId-b and the Adriatic, and update and publish the standard as a SISP protocol.	a) Science Requirements b) Advisory Requirements Required to ensure consistent approach within and between areas to meet EU directives.	3.1, 3.2	Annually	WG report chapter inshore manual offshore manual database (DATRAS)

c	Analyse the changes in mean length-at-age for sole in the North Sea, English Channel, Bristol Channel and Irish Sea. (continuation of WGBEAM work in 2014-2016)	<p>a) Science Requirements</p> <p>The large WGBEAM dataset has the potential to elucidate temporal and spatial changes in population parameters.</p> <p>b) Advisory Requirements</p> <p>Indices are being used by assessments working groups and any changes to age structure of species of interest need to be investigated.</p>	5.2	Expected output in 2017	WGBEAM 2017 update and ultimately ASC presentation
d	Provide index calculations based on DATRAS for dab in the North Sea, and plaice and sole in Divisions VIIa, VIId-g, VIIIa-b and the Adriatic.	Required to support indices for assessments	3.2	3 years	Provision of new index series to relevant WGs
e	Evaluate the results and outcomes of a workshop on index calculation methods based on DATRAS beam trawl data.	Currently, a modelled approach (delta GAM method) combining several surveys into a single index based on DATRAS data are used for several North Sea stocks (i.e. North Sea plaice, lemon sole, and dab). WGBEAM will organize a workshop on this issue. The aim of this workshop will be to evaluate and to contrast the deltaGAM method with the previously used index calculation methods with regard to the output of the stock assessment models used.	3.2, 3.3	1 year expected output in 2019	WG report chapter

Summary of the Work Plan

Year 1	Annual standard outputs for a,b. Continue analysis on ToR d, c. Started to analyse the macro epibenthos catches in species composition and quantity of at least IBTS Q3 and Beam Trawl Survey catches.
Year 2	Annual standard outputs for a,b. Continue analysis on ToR c,d.
Year 3	Annual standard outputs for a,b. Continue analysis on ToR c,d. Complete ToR e.

Supporting information

Priority	The current activities of this Group will lead ICES into issues related to the ecosystem affects of fisheries, especially with regard to the application of the Precautionary Approach. Several indices produced by WGBEAM are already included in Category 1 stock assessments (NS sole, NS plaice, Biscay sole, NS dab since 2016) and data collected on beam trawl surveys are increasingly used to produce indices for Category 3 stock assessments. Consequently, these activities are considered to have a very high priority.
Resource requirements	The research programmes which provide the main input to this group are already underway, and resources are already committed. The additional resource required to undertake additional activities in the framework of this group is negligible.
Participants	The Group is normally attended by some 10–15 members and guests.
Secretariat facilities	None.
Financial	No financial implications.
Linkages to ACOM and groups under ACOM	As WGBEAM directly calculates and discusses survey indices for stock assessments, and coordinates surveys from which data are used in other stock assessments, there is a clear linkage to ACOM and some of the stock assessment WGs under is coordination (WGNSSK, WGCSE, WGBBI, WGEF, WGINOSE, WGISUR).
Linkages to other committees or groups	There is a very close working relationship with all the groups of the EOSG. Joint sessions are sometimes organized (e.g. with WGCAN in 2014). It is also very relevant to the Working Group on Ecosystem Effects of Fisheries.
Linkages to other organizations	The work of this group is closely aligned with similar work in FAO.

3 Summary of work plan

Year 1	Annual standard outputs for a,b. ToR c in progress. Continue analysis on ToR d. ToR e: Started to analyse the macro epibenthos catches in species composition and quantity of at least IBTS Q3 and Beam Trawl Survey catches.
Year 2	Annual standard outputs for a,b. Continue analysis on ToR c,d.
Year 3	Annual standard outputs for a,b. Continue analysis on ToR c,d. Complete ToR e.

4 List of Outcomes and Achievements of the WG in this delivery period

In this delivery period, WGBEAM has worked on and achieved the following:

1. Update and interpretation of abundance index time-series for sole and plaice in offshore and inshore beam trawl surveys:
 - Update of offshore and inshore survey time-series for plaice and sole
 - Update of deltaGAM indices for North Sea plaice and North Sea dab
2. Increase standardization of the surveys:
 - Belgium staff participated in Dutch beam trawl survey.
3. Data quality and availability:
 - Revision of offshore beam trawl manual. Finalization of manual in progress.
 - Progress in incorporation of the Adriatic beam trawl survey into DATRAS
4. Other activities:
 - Analysis of the changes in mean length-at-age for sole and plaice in the North Sea, the English Channel, the Bristol Channel, and the Irish Sea (to be continued)
 - Analysis of benthic communities of BTS offshore surveys in relation to fish data from BTS and IBTSQ3.
 - Feedback to the DATRAS governance group on the need of variables to incorporate into DATRAS

5 Progress report on ToRs and workplan

5.1 Tabulate, report and evaluate population abundance indices by age-group for sole, plaice and dab and other species if required in the North Sea, Division VIIa, Divisions VIIId-g, Divisions VIIlab and the Adriatic taking into account the key issues involved in the index calculation (Tor a).

5.1.1 Abundance indices by age-group for plaice and sole for the offshore surveys

5.1.1.1 Sole

North Sea – Subarea 4

Time-series trends for sole in the North Sea, based on the Netherlands Isis offshore survey, are shown in Figure 5.1.1.1a in Annex 5.3. This survey indicates that recent year classes have been mainly poor with the 1 group below the long-term arithmetic mean for the last five years (2012 – 2017). The 1-group in 2017 was higher than in 2016, and similar to the 1-groups in 2014 and 2015. The poor 2011 year class (age group 1 in 2012) resulted in below average age groups up to age group 3 (2014). However, in 2015 this cohort is well above the long term average and that trend continued in 2016. In general, there has been an increase in older fish (4+ group), with values well above the long-term arithmetic mean for the last 4 years (2013-2017). The spatial coverage of the Netherlands Tridens survey makes it unsuitable for monitoring sole abundance.

Time-series trends for sole in the Southern North Sea, based on the UK offshore survey, are depicted in Figure 5.1.1.1b in Annex 5.3. Here, the number of one-year olds was below the long-term mean from 2012 - 2014. In 2015 the highest value for age 1 for the whole time-series was observed until a new record was set in 2017, but in 2016 the value for this age group was well below the average. Strong cohorts of 2 year old fish in 2016 and 3 year old fish in 2017 were observed, a result of the large numbers observed of 1 year old fish in 2015.

Western Waters - Subarea 7

The indices for sole from area 7 stocks are summarized in Figure 5.1.1.1c-f in Annex 5.3.

Division 7d

After three years (2009–2011) during which the relative abundance of sole in the Eastern English Channel was either at or above the time-series averages across all age groups, this trend did not continue in 2012 and in 2013, when the numbers of one and two year olds were far below the long-term averages, with the number of one year olds in 2013 (the incoming year class 2012) being the second lowest of the time-series. In 2014 and 2015 the number of one year old sole was again far above the average and among the five highest values recorded. This trend did not continue in 2016, as the number of one year old sole was below the long term mean, while the numbers in 2017 were similar to the values in 2014 and 2015. The very low observed value for the 2013 year class was not observed at that low level for the 2015 group 2 or the 2016 group 3 which were above the average.

The relative abundances for the 1–3 age groups have been quite variable over time, what can often be attributed to strong 1 group recruitments that can be followed through from one year to the next.

Division 7f

The relative abundances of the age groups 1 sole in the Bristol Channel was below the time-series average for the years 2009-2014. In 2015-2017 age group 1 shows again above average value, and the value in 2017 is the highest since 2008. The low observed age group 1 in 2014 resulted in the lowest observed age group 2 value in 2015 and very low age group 3 value in 2016. The number of age group 4+ was fluctuating around the average for the last five years with values slightly above the average in 2015-2017.

Division 7a

Of all VII sole stocks, sole in the Irish Sea is clearly in the worst shape according to the beam trawl surveys carried out in this Division. Since 2005 the abundances have been below the time-series means for all age groups. In 2015 the numbers of age group 1 was observed for the first time since 2005 above the time-series average, but in 2016 and 2017 numbers below the average were observed again. The numbers of age group 3 were very high in 2017, and above the average for the first time since 2004, a result of the strong 2014 year class. However, the numbers for the 4+ group remain more or less stable at the low 2005–2017 level. As for most other sole stocks, peaks in the abundance of 1 groups can generally be tracked through to following years.

Division 8 a,b

The ORHAGO survey time-series of age group abundances of sole in the Bay of Biscay (Figure 5.1.1.1g) are marked by the arrival of two below average year classes in 2011 and 2012 at age 1. The yearly advance in age of these two year classes can be followed from age 1 to 3. Their abundance indices in successive years are consistent between them. The five following year classes are close to the mean at age 1 from 2013 onwards. Their abundance indices at age 2 are consistent with age 1 estimates. The 4+ age group abundance indices have decreased from 2013 to 2016. This trend is due to the cumulative effect of the increase in age of three year classes (2010, 2011 and 2012) which are below average at age 3. However, the 4+ age group abundance indices are above the long-term mean from 2012 onwards.

Northern Adriatic Sea

Figure 5.1.1.1h shows the time-series trends in sole for the northern Adriatic Sea, based on the SoleMon offshore beam trawl surveys. Although sole otoliths were collected since 2007, the ageing is still in progress and for some years, a survey age-length key is not yet available. So age slicing, based on von Bertalanffy parameters (L_{inf} : 39.6; k : 0.44, t_0 : -0.46), was carried out using LFDA 5.0.

This survey indicates that the 2017 0 age group of sole in the northern Adriatic has been lower than the level of the long-term arithmetic mean. Ages 1 in 2017 cruise were little higher than the long-term arithmetic mean. At age 2, 3 and 4+ the 2017 cruise yielded the highest index value of the time-series. Overall is possible to notice a good internal consistency of the cohorts, in particular the high recruitment observed in 2013 can be followed in the succeeding years.

5.1.1.2 Plaice

North Sea – Subarea 4

Figures 5.1.1.2a and 5.1.1.2b in Annex 5.4 show trends in the indices for North Sea plaice from the Netherlands Isis and Tridens surveys. The Isis survey covers mainly the southern North Sea, whereas the Tridens extends substantially further north and west.

The Isis survey indicates that recruitment has been below average in most years since the strong 2001 year class became apparent as one year olds in 2002. In 2014, as detected in 2009, 2011 and 2013, the observed number of one year olds was higher than the long-term mean. In 2015 and 2016 it was again below the average, while it was again above the long-term mean in 2017. The Tridens survey confirmed the strong 2001 year class, but also documented a series of seven consecutive incoming year classes that were above average from 2007 onwards, including 2014. This pattern is visible at all ages in this survey, and the cohorts can be tracked over time really well. The 2016 year class is the highest on record, evident by the high values of 1-group in 2017. The clear increasing trend in the age 4+ group is continuing in 2017 with the highest record of the time-series ever, and this increasing trend is clearly visible in all ages from 4-10. The combined Isis-Tridens index (Figure 5.1.1.2c in Annex 5.4) shows above average numbers for group 1 in 2017, for the first time since 2014. It also shows above average numbers-at-ages 2-4+ in 2017, with an increasing trend since the beginning of the 21st century for ages 4+. It is not clear where the larger numbers of four year olds in 2007–2009 come from in the Tridens and combined indices.

The population abundance series for plaice from the UK offshore survey (depicted in Figure 5.1.1.2d), tells a different story for the Southern North Sea. Here, the high incoming year classes 2010 and 2013 are apparent as the biggest since 2002. Differently from Dutch surveys the number of incoming recruits at age 1 (year class 2014) is clearly below the long-term average in 2015, and similar story can be said about year class 2015, which is well below the average in 2016. The increasing trend in numbers which can be seen from the combined Dutch survey index for age group 3 and 4+ is not that clearly visible in the UK offshore survey in this area, although for age group 3 a strong increase was recorded in 2016 and age group 4+ has been above the average for the last five years.

Western Waters - Subarea 7

The indices for plaice from area 7 stocks are summarized in Figure 5.1.1.2e-h in Annex 5.4.

Division 7d

The abundance at age 1 after the drop observed in 2012, was again close to the long-term arithmetic mean (year class 2012) in 2013. In 2014 the abundance at age 1 was observed to be exceptional high and is by far the highest record of the time-series. However, in 2015 the number of age group 1 dropped again to the long term average and dropped even further in 2016 when the smallest number since 2005 was observed. It rebounded again in 2017 and was slightly above the long term mean. In 2014 the observed number of age group 2 was the highest ever observed so far in the time-series, but the value for 2015 was even higher than that. The numbers of age group 2 in 2016 and 2017 were lower than in 2014 and 2015, but still well above the long term average. As a result of the good year classes 2009-2011 the numbers of age 4+ were the highest ever observed in the time-series for the years 2013-2017. Cohorts can be generally well tracked into all or some of the following years in this survey.

Division 7f

The relative abundance at age 1 increased considerably for plaice in the Bristol Channel in 2013, reaching a value similar to what was observed in 2010 and 2011. This trend continued in 2014 and resulted in the highest record for age group one in the time-series observed so far. However, in 2015-2017 the lowest values ever were recorded. The strong year class 2010 can be tracked over the years, and produced time-series

peaks of 3 in 2013 and 4+ year olds in 2014. The numbers in the 4+ group were again the high in 2015 and 2016, and a record high value was observed in 2017. Since 2009 the numbers of this age group consistently increased. Earlier in the survey history, abundance peaks of age 1 fish could not always be tracked over the following years as well as in recent years.

Division 7a

The age 1 abundance of plaice in the Irish Sea in 2014 was above the level of the long-term average with the highest record of the time-series. Since 2002–2003 the abundance figures have remained relatively constant for all age groups (with a lower value for age 1 in 2005–2006 as the main exception), and noticeably above those recorded for the years prior to this date. In 2015 the observed number of age group 1 was well below the time-series mean and in 2016 and 2017, the smallest numbers of the series were observed. However, as opposed to sole in this area, plaice in VIIa seems to be characterized by a healthy stock status, with numbers for the 4+ group in 2013–2017 being the highest of the time-series and an increasing trend since the beginning of the time-series in 1995. Cohorts can be tracked relatively well over consecutive years in this survey.

5.1.2 Abundance indices by age-group for plaice and sole for the inshore surveys

The Belgian Demersal Young Fish Survey (DYFS), the German DYFS and the Dutch Demersal Fish Survey (DFS) together cover most of the coastal and estuarine waters along the continental coast from the French-Belgian border to Esbjerg in Denmark. All these surveys were initiated in the 1970s.

Previously, the three continental surveys and the UK Young Fish Survey (YFS) were combined into international inshore indices for 0 and 1 group plaice and sole. Due to termination of the UK YFS and the spring survey of the German DYFS, the combined 0 group indices are now calculated using Belgian, Dutch and German data, and the combined 1 group indices using Belgian and Dutch data only. The Dutch, and hence the combined indices, are calculated from 1990 onwards, mainly due to a change in the survey design of the Dutch DFS in 1990.

The Dutch Sole Net Survey (SNS) was initiated in 1970 and samples transects further offshore than the other inshore surveys. The SNS survey area overlaps with those of the Dutch DFS and BTS-Isis.

The Working Group on the Assessment of Demersal Stocks in the North Sea and Skagerrak (WGNSSK) uses the SNS indices and the combined inshore indices for recruitment estimates of the North Sea plaice and sole stocks. The SNS indices are also used as tuning fleet in the assessment models for plaice and sole. The combined inshore indices are considered to be suitable for 0 group plaice and sole, but less suitable for 1 group sole and even more so for 1 group plaice, because of the spatial coverage of the survey in relation to the spatial distribution of these age groups. The SNS is considered to be suitable for plaice and sole age groups 1 to 4.

The abundance indices are presented in Annex 6.1 for the D(Y)FS and Annex 6.2 for the SNS. The corresponding combined inshore indices and the SNS indices are plotted for 1990 to 2017 in Figures 5.1.2.1 and 5.1.2.2 respectively (Annexes 6.1 and 6.2).

5.1.2.1 Sole

The combined inshore indices for 0 and 1 group sole were below average in 2017. The 0 group index in 2017 was quite a bit higher than in 2016 (Figure 5.1.2.1 in Annex 6.1). In the SNS, age groups 1 and 2 have been below the average in 2016 and 2017. The

strong year class 2 of 2015 is now represented in this year's age group 4 which is now among the highest values estimated since 1990 (Figure 5.1.2.2 in Annex 6.2).

A year effect can be observed for sole in 2012, where the total for all age groups was the lowest in the entire time-series since 1990 (Figure 5.1.2.2 in Annex 6.2). This was the year where the SNS was carried out on the RV Tridens instead of the RV Isis (ICES WGBEAM 2013) and the observed year effect may indicate that the change in vessel has caused a bias in the SNS indices. The internal consistency is relatively good until age 3 but becomes weaker for age group 4, especially in the most recent years.

5.1.2.2 Plaice

The combined inshore indices for 0 and 1 group plaice were below average in 2017 (Figure 5.1.2.1 in Annex 6.1). In the SNS, the group 1, 2 and 3 indices are below average while the 4 group indices are above the average (Figure 5.1.2.2 in Annex 6.2).

Although a year effect in 2012 in the SNS is far less evident for plaice than for sole (Figure 5.1.2.2 in Annex 6.2), this year should also be treated with caution for plaice. The use of a different vessel in this year may also have affected the catchability of plaice in 2012 (see above). The internal consistency is rather poor for plaice in the most recent survey years.

5.1.3 New combined offshore beam trawl survey indices for plaice and dab

During the recent benchmark workshops for dab (ICES, 2016) and plaice (ICES, 2017) it was agreed to use combined survey indices for each of the stocks using data from different beam trawl surveys. In both cases a GAM model approach (Berg et al., 2014) was applied to construct age based survey indices making use of the DATRAS database.

5.1.3.1 Plaice

The combined beam trawl survey index for the North Sea plaice stock (ple.27.420) includes data from different beam trawl surveys (1996-2016, ages 1-9) which are available in DATRAS. For details see the report of the Benchmark Workshop on North Sea Stocks WKNSEA 2017 (ICES, 2017). The index was updated during the WGBEAM 2018 meeting and by the stock coordinator of plaice (Annex 7; Figure 1).

Table 5.1.3.1. Overview of data included in the North Sea plaice index calculation

ENG	END	BT4A	2008-2017	

5.1.3.2 Dab

The combined beam trawl survey index for the North Sea dab stock (dab.27.3a4) includes data from different beam trawl surveys (2003-2016, ages 1-6) which are available in DATRAS. For details see the report of the Benchmark Workshop on North Sea Stocks WKNSEA 2016 (ICES, 2016). The index was updated during the WGBEAM 2018 meeting (Annex 7; Figure 2).

Table 5.1.3.2. Overview of data included in the North Sea dab index calculation

Country	Vessel	Gear	Years	Ages
GFR	SOL	BT7	2003	1-6
GFR	SOL2	BT7	2004-2005, 2007-2017	
NED	ISI	BT8	2003-2016	
NED	TRI2	BT8	2003-2017	

5.2 Trawl surveys in the North Sea and Division 7a, 7d-g, 8a-b and the Adriatic (ToR a).

5.2.1 Results of 2017 surveys

5.2.1.1 Offshore beam trawl surveys

5.2.1.1.1 Participation and coverage of the area

Eleven surveys were carried out, covering the North Sea, 5a, 7d, 7e, 7fg, 7a, 8a, 8b and the Northern Adriatic Sea. The participating vessels and time of the surveys are listed in Table 5.2.1.1. Further details (areas covered, technical specifications) by country are given in Annex 4.1.

Table 5.2.1.1. Overview of offshore beam trawl surveys during 2017.

Country	Vessel	Area	Dates	Gear
Belgium	Belgica	southern North Sea	28 Aug – 08 Sep 2017	4m beam
England	Endeavour	7d, 4c	19 Jul – 01 Aug 2017	4m beam
England	Endeavour	7a, 7f	06 – 26 Sep 2017	4m beam
England	Endeavour	7e, Celtic Sea	07 Mar – 05 Apr 2017	4m beam
France	Côtes de la Manche	8a, 8b	02 – 21 Nov 2017	4m beam
Germany	Solea	German Bight	18 Aug – 04 Sep 2017	7m beam
Iceland	Bjarni Sæmundsson RE-30	Entire coast of Iceland	24. Aug – 07 Sep 2017	4m beam
Ireland	Celtic Explorer	western Celtic sea	07 – 16 Mar 2017	4m beam
Italy/Slovenia	G. Dallaporta	northern Adriatic Sea	10 Nov – 09 Dec 2017	3.5m beam
Netherlands	Tridens	central North Sea	21 Aug – 15 Sep 2017	8m beam + flip-up rope
Netherlands	Tridens	southern North Sea	31 Jul – 18 Aug 2017	8m beam

5.2.1.1.2 Survey results

A summary of each of the offshore surveys is to be found in Annex 8.

5.2.1.1.3 Staff exchanges (ToR b)

In the context of staff exchange and standardization of survey methods a member of ILVO (Institute for Agricultural, Fisheries and Food Research, Belgium) participated in the Dutch offshore Beam Trawl Survey 2017 organized by WMR (Wageningen Marine Research, Netherlands) in ICES division 4. The observations on differences and similarities by the staff involved in this exchange should help the involved parties and WGBEAM to better understand and coordinate the surveys from an international perspective. See Annex 9 for a detailed report.

No staff exchanges are planned for 2018

5.2.1.2. Inshore beam trawl surveys

5.2.1.2.1 Participation and coverage of the area

The inshore surveys in the North Sea are carried out by Belgium (Demersal Young Fish Survey-DYFS), Germany (DYFS) and the Netherlands (Demersal Fish Survey-DFS). UK (Young Fish Survey-YFS) ceased the survey due financial constraints in 2012.

The Sole Net Survey (SNS), which is carried out by the Netherlands in the North Sea, is classified as an inshore survey, but ‘nearshore’ may be more appropriate because the area covered is further offshore than the other inshore surveys.

The participating vessels and time of the cruises are listed in Table 5.2.1.2. Further details (areas covered, technical specifications) by country are given in Annex 4.2.

Table 5.2.1.2. Overview of surveys during 2017.

Country	Vessel	Area	Dates	Gear
Belgium	Simon Stevin	Belgian coastal zone	11 Sep – 20 Sep	6 m shrimp trawl
Germany	Chartered vessel & Clupea	German Bight and German Wadden Sea	25 Aug – 29 Sept	3 m shrimp trawl
Netherlands (SNS)	Isis	Dutch coastal zone	15 Sept – 28 Sept	6 m beam trawl
Netherlands	Luctor	Scheldt estuary	4 Sep – 21 Sep	3 m shrimp trawl
Netherlands	Stern	Dutch Wadden Sea	28 Aug – 29 Sep	3 m shrimp trawl
Netherlands	Isis	Dutch coastal zone and German Bight	04 Oct – 09 Nov (5 weeks in the period)	6 m shrimp trawl

A summary of each of the surveys is to be found in in annex 8.

5.2.1.2.2. Staff exchanges (ToR b)

No staff exchanges planned for 2018.

5.3 Analyse the changes in mean length-at-age for sole and plaice in the North Sea, English Channel, Bristol Channel, and Irish Sea (ToR c)

Trends in mean length-at-age were examined for two flatfish species: plaice and sole. Comparison of trends across areas and species can help us evaluate hypotheses on causal factors underlying growth changes. Multidecadal datasets from beam trawl surveys in the North Sea, English Channel, Bristol Channel, Irish Sea and Bay of Biscay are currently available through DATRAS or otherwise available to WGBEAM. These data allow a large-scale comparison using the same methodology for different areas and species. Weighted mean length-at-age was calculated, for males and females separately, by combining catch data and biological sampling data. The preliminary results generally indicate declining growth rates across the stocks examined, but they also indicate different timings and rates of decline between species, areas and age groups.

These changes appear to be more complex than a response to changes in temperature as frequently proposed. It appears there may be other factors relevant in explaining these changes.

Progress in 2018 and planning of the completion of this ToR c

The datasets included in the analyses have been elaborated:

- updated for the years 2016 and 2017
- German BTS data in DATRAS elaborated for the years 1995-2001
- Belgian BTS data now available in DATRAS for the years 2010-2017
- Full time-series of UK data for the western English Channel (1989-2013) available through WGBEAM

The work-up of the data were scrutinised. Most important change was the distinction of ALK (age-length-key) areas within the individual UK surveys. Up till now, different ALK areas within one survey had only been applied for the Dutch surveys.

Two approaches for analysing changes in mean length-at-age were examined. The results of the two approaches were in line with each other; they both clearly show trends in length-at-age that differ between species, stocks and age-groups. Crude comparison of these trends with stock assessment information suggests a correlation with population size.

This work will be completed, in the form of a draft manuscript submitted to a peer-reviewed journal, prior to the next WGBEAM meeting in 2019.

5.4 Other activities

5.4.1 Feedback for DATRAS governance group

5.4.1.1 DATRAS governance group

In January 2018, the DATRAS governance group was installed. It is a group under the responsibility of the ICES Data and Information Group.

The main goals of the group are:

1. Elaborate the framework on the governance of DATRAS
2. Oversee and advise on the interpretation and prioritization of recommendations from expert groups addressed to DATRAS
3. Align DATRAS over the different surveys
4. Provide a platform for end-user feedback to the DATRAS system

A full overview of tasks of the DATRAS governance group can be found in the [DIG 2017 report, Annex 9](#).

The governance group will consist of a DIG representative who will chair the group, (Ingeborg de Boois), representatives from ICES Data Centre (Anna Osypchuk, Vaishav Soni), and data-submitters from different surveys in DATRAS, representing all ICES survey planning groups delivering data to DATRAS: WGBIFS (Henrik Degel), IBTSWG (Finlay Burns), WGBEAM (Wim Allegaert).

The group had its first meeting in February 2018, and decided to collect feedback on variables that currently cannot be stored in DATRAS, or are not available in the current reporting format for the specific surveys.

5.4.1.2 WGBEAM feedback to governance group

DATRAS reporting format

WGBEAM took the inshore reporting format as a starting point, and first of all, would like to adopt that also for the offshore beam trawl surveys.

Add additional variables (to the current inshore format):

- HH: Check if tide direction can be put into DATRAS, in bottom current speed?
- HH: BycSpecreccode -add to vocab if litter has been collected during the survey
- CA: stratification by length class/weight/sex
- CA: How many otoliths were planned by length class in the design (AreaType, stratification by) –should be variable on a species level and even on length class.

New vocabulary:

- CA: Survey stratification; survey stratum: on what (spatial) stratification have the otoliths been collected? After discussion it was decided that all countries should check if the appropriate AreaType is available in the ICES vocabulary (vocab.ices.dk) and apply the correct vocabulary to the data. For the following surveys additional vocabulary for the offshore beam trawl surveys is needed (if possible, also provide shapefiles):
 - IBTS roundfish areas (NED); shapefile can be taken from IBTS AreaType roundfish areas
 - BTS NED index areas (NED); shapefile to be delivered
 - ENG Q1 (ENG)

Descriptions:

For some variables in the reporting format the descriptions are not clear, e.g. CatCatchIdentifier. It would help when the variable descriptions are being reviewed and updated.

Other issues

- Export: also add scientific names to Exchange data. Currently in the download of Exchange data only valid ApiaID is presented. WGBEAM would like to also see scientific species names in the Exchange file (based on the valid AphiaID);
- The upload facility does not accept Specval=1 and specval=4 for the same haul, species and sex. This should be made possible, as it quite often occurs that e.g. edible crab is measured in a haul and a smashed crab is only counted, as it could be measured.
- If specval=4 then LengthClassCode, MinLengthClass and HLNoAtLength = -9; if validity code is 4 then LengthClassCode, MinLengthClass and HLNoAtLength = -9 (DATRAS screening facility). It is highly favourable to be able to add the number counted per species in DATRAS, and so, also submit the actual subsampling factor.

- There is a wish to be able to link up the data in the stomach database with DATRAS data

Action WGBEAM:

Check if areatype has been filled in correctly for offshore and inshore data

5.4.2 Analysis of epibenthic community data from the Dutch offshore beam trawl surveys

Details on this analysis is given in Annex 10 (WD1)

Background:

WKPIMP 2016 requested that WGBEAM 'Compare the macro-epibenthos catches in species composition and quantity of at least IBTS Q3 and Beam Trawl Survey catches'. WGBEAM was unable to fully complete the request as the IBTS Q3 data on epibenthos is not available on DATRAS. Instead WGBEAM evaluated the epibenthic community structure from the Dutch BTS surveys carried out on Tridens and ISIS with those of the fish communities of both the beam trawl and GOV (IBTS Q1 and Q3 combined). Haul locations and number of hauls differ between these surveys, so for the purposes of this analysis the data were aggregated by ICES-rectangle and year combinations to enable comparisons. The analysis was limited to the rectangle-year combinations where all three data types were available on DATRAS.

WGBEAM concluded:

General community structure is highly consistent between epibenthic communities and fish communities as sampled simultaneously by the beam trawl and independently in the GOV.

For the three communities examined patterns are spatio-temporally very consistent and at the very least do not suggest large changes over time. Spatial differences are much more important than changes over time suggesting that without considering spatial effects comparisons between years is unlikely to detect changes of the magnitude contained in the time-series.

Observed differences in the spatial extent of different clusters are largely artefacts of the clustering method chosen. Ordination analysis suggest that spatial changes are gradual and clustering responds differently to these changes. Correlation between the correspondence analysis eigenvectors is highly significant across the different communities with beam trawl and GOV fish communities having an $r^2=0.934$ on the first axes, and both fish communities correlating with epibenthic communities (r^2 0.88 and 0.87 for GOV and beam trawls respectively).

Spatial scales of community variability are significantly larger than the inter station distances, and correlation between communities sampled by different surveys (not the same location) suggest that habitats are either homogenous or a highly consistent mosaic of different communities at spatial scales much smaller than those of the trawls. In any case possible scales of marine spatial management are significantly larger than the scales of sampling.

The working group concludes that epibenthic sampling from gears designed for fishing can be indicative of epibenthic species at scales relevant to management and that combining epibenthic catches from the North Sea beam trawl surveys for integrated analysis with fish catches should be possible at least at the general level. Further analysis is necessary to investigate the utility for more specific purposes.

6 Revision to the work plan and justification

No revision was made during the meeting.

7 Next meeting

The next meeting for WGBEAM is scheduled to be 18 – 22 March 2019, at ICES Headquarters in Copenhagen.

Annex 2: Recommendations

Recommendation	Adressed to
1. During the WGBEAM 2018 survey summary sheets were revised and put in a new table format. This table now contains relevant information for the assessment working groups and all other potential data users. WGBEAM recommends that ACOM takes the responsibility to delegate update of the assessment used information to the relevant assessment working groups.	ACOM
2. WGBEAM recommends to ICES data centre to develop R-based and git hub-based swept-area CPUE calculation procedure.	ICES Data centre
3. WGBEAM recommends ACOM to consider whether it is necessary for French inshore beam trawl survey data, as used in the assessment of sole in subarea 7d, to be included in the survey coordination by WGBEAM.	ACOM
4. WGBEAM recommends to WGECO and WGINOSE to investigate whether the data used in the analyses on benthic communities can be used as indices or indicators.	WGECO, WGINOSE

Actions

- Restructure information of the Offshore manual in order to increase consistency and clarity particularly of the survey design elements, include Q1SWECOS and resubmit to EOSG chair (Ingeborg de Boois, Kay Panten, Loes Vandecasteele, Sven Kupschus).
- Continue work on inshore BTS manual and send to EOSG-chair for review in the process towards publication in the SISP-series. This is addressed to Loes Vandecasteele, Ingeborg de Boois, Gary Burt, Holger Haslob, Loes Bolle.
- IFREMER to give priority to the upload of beam trawl survey data to DATRAS. This is addressed to ACOM (France). In Progress.
- WGBEAM member countries to continue the upload of: - inshore beam trawl survey data to DATRAS; - offshore beam trawl survey including all taxa. This is addressed to Ingeborg de Boois, Loes Vandecasteele, Gary Burt, Kay Panten. BEL: inshore in progress; offshore done (2010-2016), in progress for earlier years. GER: inshore in progress; offshore (1998 – 2016) NED: inshore DYFS 2010-2016 submitted; offshore done UK: inshore in progress; Western Channel to be completed, all others done.
- Sort out submission of SNS data to DATRAS. This is addressed to ICES Data Centre (Vaishav Soni, Anna Osypchuk), Ingeborg de Boois. Dialogue between ICES Data Centre and NED, see WGBEAM 2017 report chapter 5.4.2.2. for progress.
- Continue the work on DATRAS checking procedures to be made available in an R-script so national data can be screened prior to the DATRAS screening, making the process more efficient. This is addressed to ICES Data Centre (Vaishav Soni, Anna Osypchuk). Long-term aim in progress.
- If time and weather allows: - overlapping hauls are carried out by countries operating in the same area; - the ICES Rectangles are visited that just miss out in the survey selection criteria for use in MSFD GES assessment (based on list of M. Moriarty); - NED and GFR continue to carry out side-by-side or overlapping hauls during their Q3 inshore beam trawl surveys in the context of gear comparisons, mainly to investigate differences in catchability for brown shrimp. This is addressed to all. No overlapping tows done in 2017.
- CPUE per length per Hour and Swept-area for Inshore surveys (currently DYFS). A request form has been sent in to accessions@ices.dk. This is addressed to Ingeborg de Boois, Vaishav Soni. In progress.
- Restrict access to previous versions of data uploaded into DATRAS to data submitters. Previous versions of uploaded data should be available upon request only for all other users. This is addressed to ICES data center.

Annex 3: Terms of Reference

WGBEAM – Working Group on Beam Trawl Surveys

2016/MA2/SSGIEOM11 The **Working Group on Beam Trawl Surveys** (WGBEAM), chaired by Holger Haslob, Germany, will work on ToRs and generate deliverables as listed in the Table below.

	MEETING DATES	VENUE	REPORTING DETAILS	COMMENTS (CHANGE IN CHAIR, ETC.)
Year 2017	4-7 April	Galway, Ireland	Interim report by 1 June 2017 to ACOM-SCICOM	New chair
Year 2018	10-13 April	IJmuiden, The Netherlands	Interim report by 25 May 2018 to ACOM-SCICOM	
Year 2019	1-5 April	ICES HQ, Copenhagen, Denmark	Final report by 17 May 2019 to ACOM-SCICOM	

ToR descriptors

TO R	DESCRIPTION	BACKGROUND	Science Plan codes	DURATION	EXPECTED DELIVERABLES
a	Tabulate report and evaluate population abundance indices by age-group for sole, plaice and dab and other species if required in the North Sea, Division VIIa, Divisions VIIId-g, Divisions VIIIab and the Adriatic taking into account the key issues involved in the index calculation.	a) Science Requirements Length-at-age analysis b) Advisory Requirements Required to support indices for assessments c) Requirements from other EGs Specific questions from other EGs possible	3.2	Annually	WG report chapter
b	Further coordinate and standardize offshore and coastal beam trawl surveys in the North Sea and Divisions VIIa, VIIId-g, VIIIa-b and the Adriatic, and update and publish the standard as a SISP protocol.	a) Science Requirements b) Advisory Requirements Required to ensure consistent approach within and between areas to meet EU directives.	3.1, 3.2	Annually	WG report chapter inshore manual offshore manual database (DATRAS)

c	Analyse the changes in mean length-at-age for sole in the North Sea, English Channel, Bristol Channel and Irish Sea. (continuation of WGBEAM work in 2014-2016)	a) Science Requirements The large WGBEAM dataset has the potential to elucidate temporal and spatial changes in population parameters. b) Advisory Requirements Indices are being used by assessments working groups and any changes to age structure of species of interest need to be investigated.	5.2	Expected output in 2017	WGBEAM 2017 update and ultimately ASC presentation
d	Provide index calculations based on DATRAS for dab in the North Sea, and plaice and sole in Divisions VIIa, VIId-g, VIIIa-b and the Adriatic.	Required to support indices for assessments	3.2	3 years	Provision of new index series to relevant WGs
e	Evaluate the results and outcomes of a workshop on index calculation methods based on DATRAS beam trawl data.	Currently, a modelled approach (delta GAM method) combining several surveys into a single index based on DATRAS data are used for several North Sea stocks (i.e. North Sea plaice, lemon sole, and dab). WGBEAM will organize a workshop on this issue. The aim of this workshop will be to evaluate and to contrast the deltaGAM method with the previously used index calculation methods with regard to the output of the stock assessment models used.	3.2, 3.3	1 year expected output in 2019	WG report chapter

Summary of the Work Plan

Year 1	Annual standard outputs for a,b. Continue analysis on ToR d, c. Started to analyse the macro epibenthos catches in species composition and quantity of at least IBTS Q3 and Beam Trawl Survey catches.
Year 2	Annual standard outputs for a,b. Continue analysis on ToR c,d.
Year 3	Annual standard outputs for a,b. Continue analysis on ToR c,d. Complete ToR e.

Supporting information

Priority	The current activities of this Group will lead ICES into issues related to the ecosystem affects of fisheries, especially with regard to the application of the Precautionary Approach. Several indices produced by WGBEAM are already included in Category 1 stock assessments (NS sole, NS plaice, Biscay sole, NS dab since 2016) and data collected on beam trawl surveys are increasingly used to produce indices for Category 3 stock assessments. Consequently, these activities are considered to have a very high priority.
Resource requirements	The research programmes which provide the main input to this group are already underway, and resources are already committed. The additional resource required to undertake additional activities in the framework of this group is negligible.
Participants	The Group is normally attended by some 10–15 members and guests.
Secretariat facilities	None.
Financial	No financial implications.
Linkages to ACOM and groups under ACOM	As WGBEAM directly calculates and discusses survey indices for stock assessments, and coordinates surveys from which data are used in other stock assessments, there is a clear linkage to ACOM and some of the stock assessment WGs under is coordination (WGNSSK, WGCSE, WGBBI, WGEF, WGINOSE, WGISUR).
Linkages to other committees or groups	There is a very close working relationship with all the groups of the EOSG. Joint sessions are sometimes organized (e.g. with WGCran in 2014). It is also very relevant to the Working Group on Ecosystem Effects of Fisheries.
Linkages to other organizations	The work of this group is closely aligned with similar work in FAO.

Annex 5.3: Figures of catch rate of sole. Offshore surveys

a) Netherlands: sole ($N \cdot hr^{-1/8m}$ trawl) North Sea (IV) RV "Isis". (Horizontal line=long-term mean for the period presented)

b) UK: sole (mean numbers per km towed for 4m beam trawl) Southern North Sea (IVc)

c) UK: sole ($N \cdot hr^{-1/8m}$ beam) Eastern English Channel (VIId)

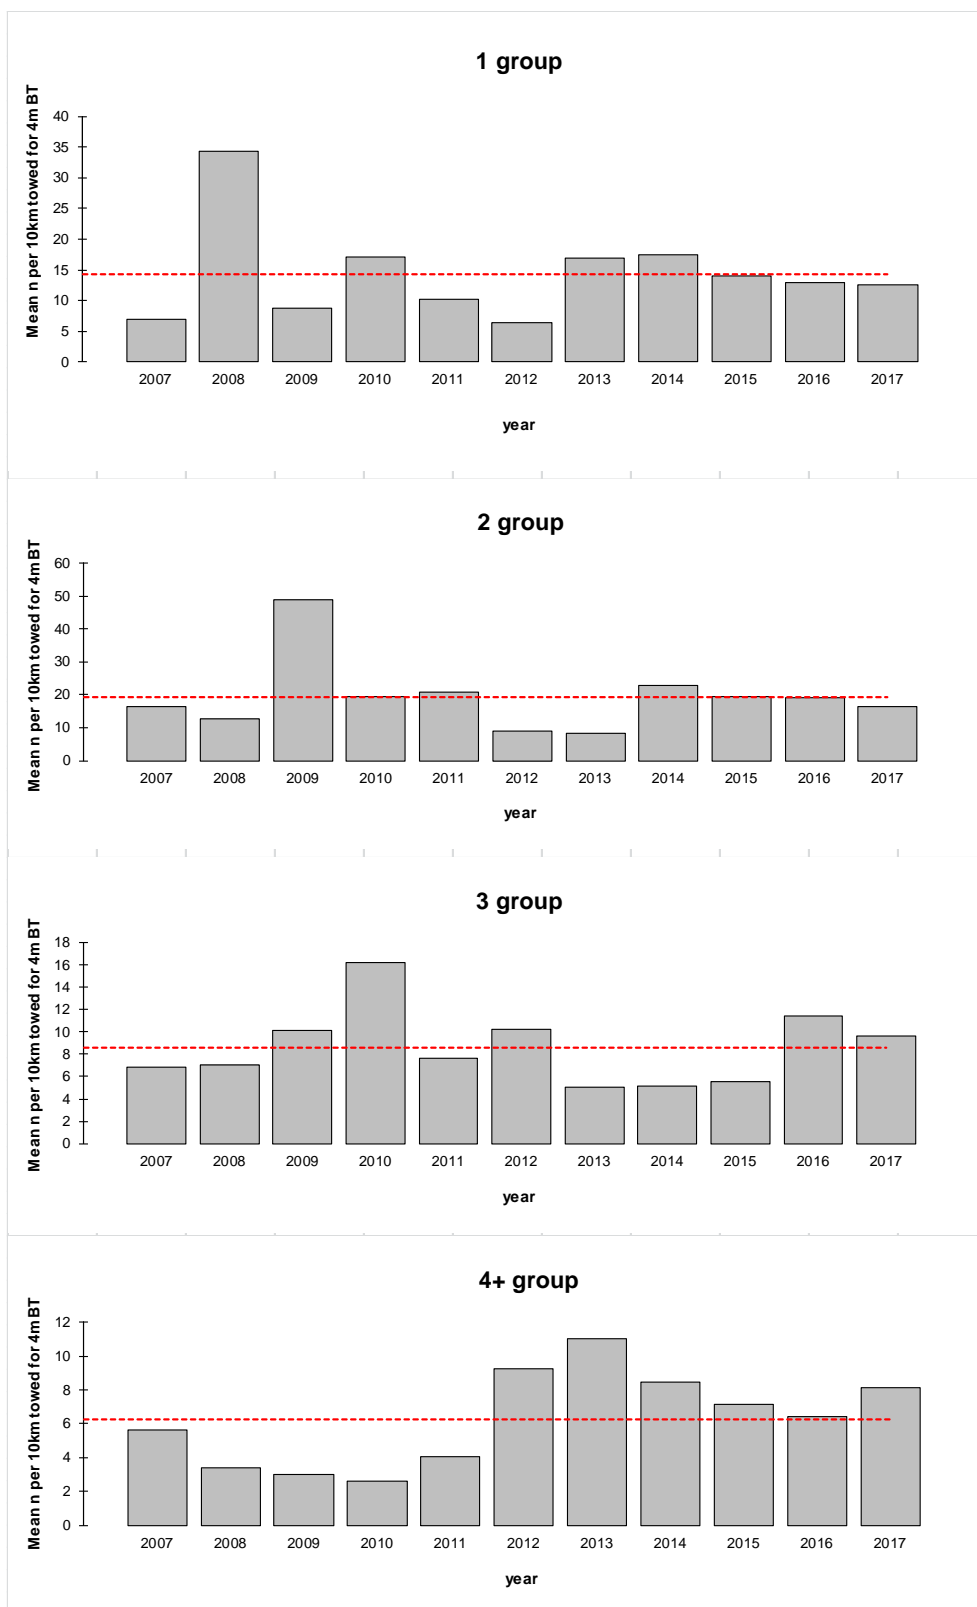

e) UK: sole (mean numbers per km towed for 4m beam trawl) Bristol Channel (VIIIf)

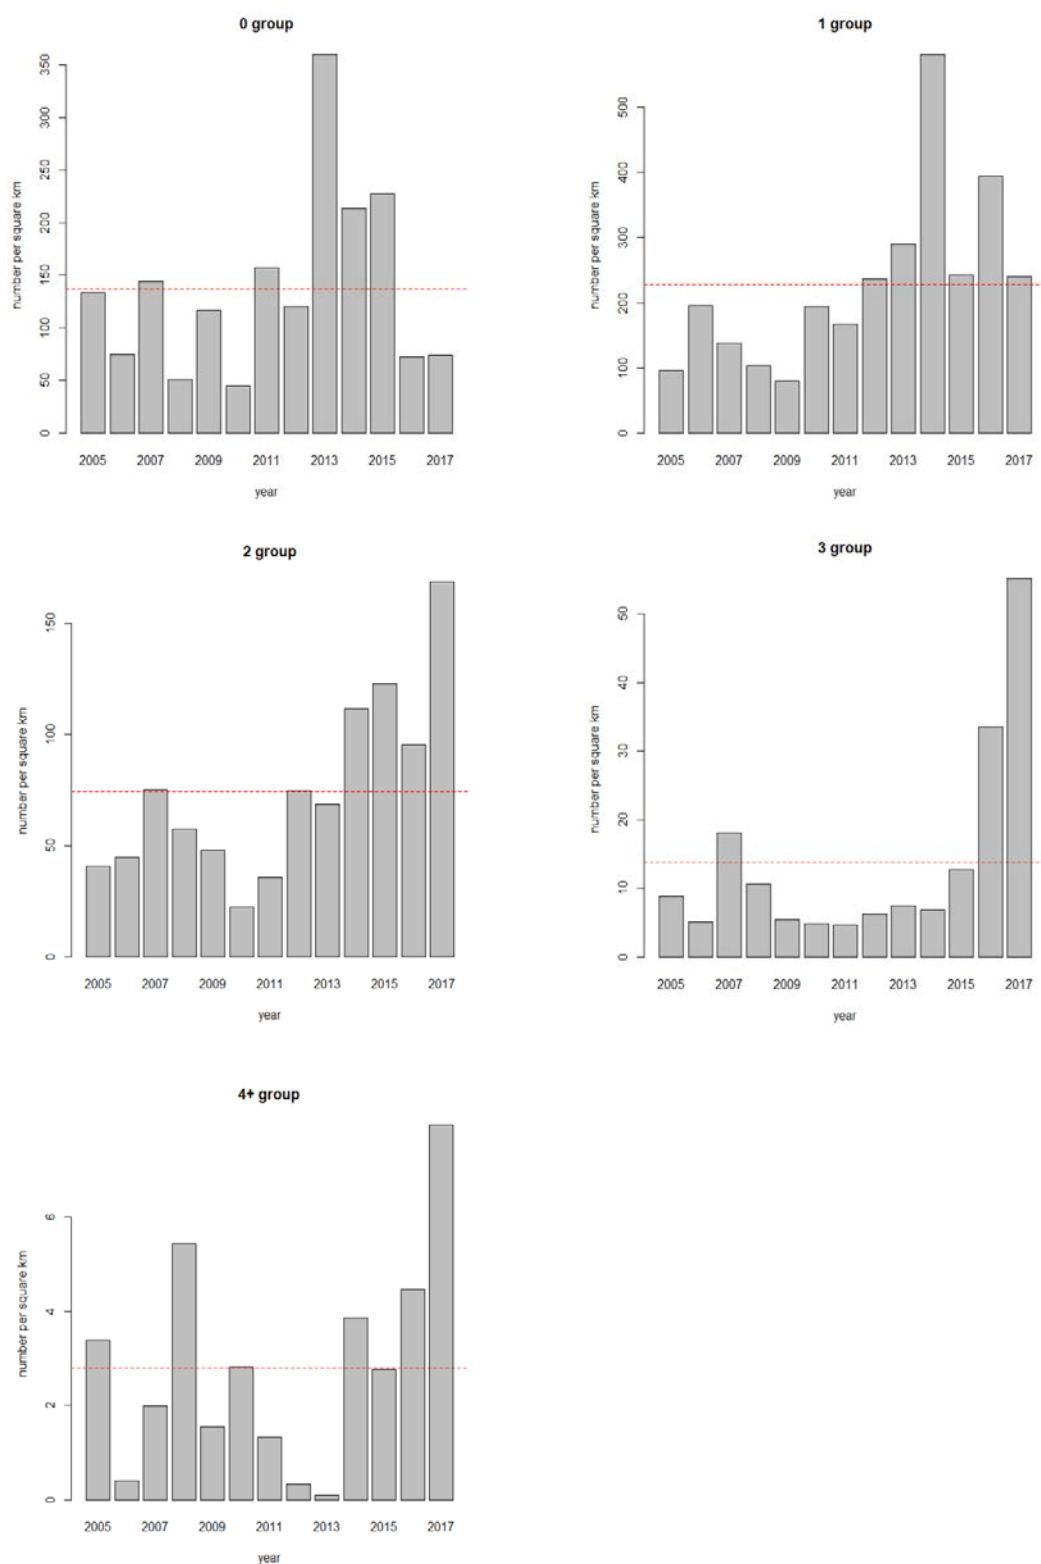

f) UK: sole (mean numbers per km towed for 4m beam trawl) Eastern Irish Sea (VIIa)

Figure 5.1.1.1. Continued

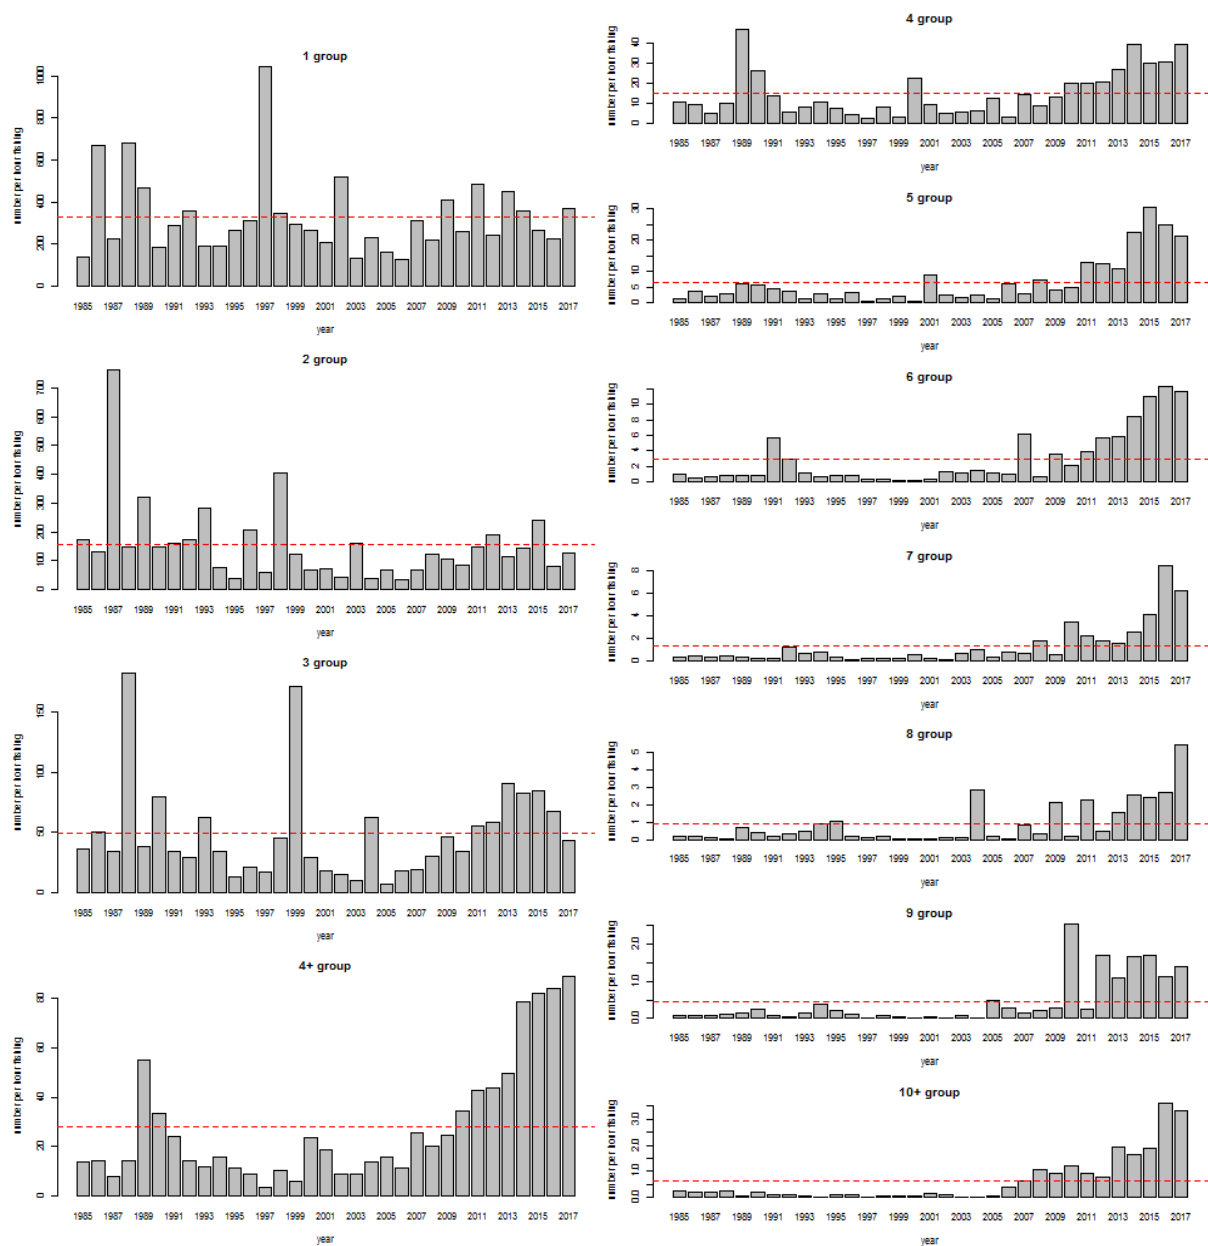

g) France: Catch rate of sole from French survey in the Bay of Biscay. (mean numbers per 10km towed for 4m beam trawl; Horizontal line=long-term mean for the period presented).

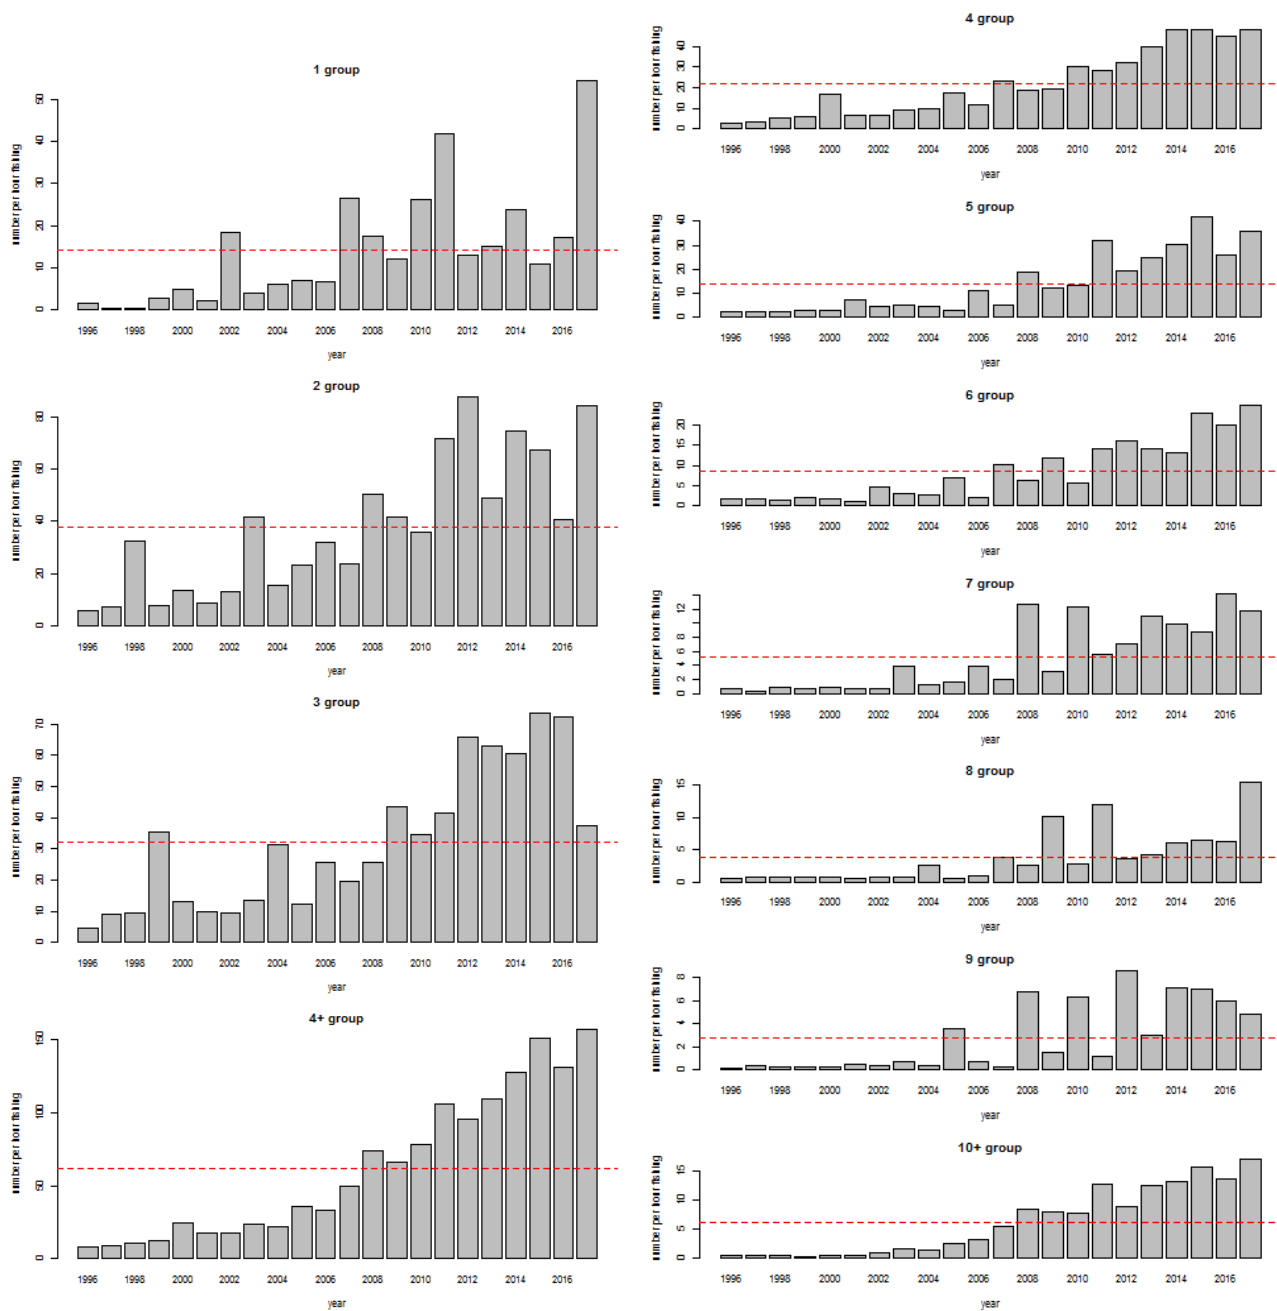

h) Italy-Slovenia-Croatia: Catch rate of sole from the Adriatic beam trawl survey. (horizontal line = long-term mean for the period presented; Croatian hauls are available only from 2016).

Annex 5.4: Figures of catch rate of plaice. offshore surveys

(a) Netherlands: plaice (N.hr⁻¹/8m trawl) North Sea (IV) RV "Isis". (Horizontal line=long-term mean for the period presented)

(b) Netherlands: plaice (N.hr⁻¹/8m trawl) North Sea (IV) RV "Tridens"

(c) Netherlands: plaice ($N \cdot hr^{-1/8m}$ trawl) North Sea (IV) RV "Isis" and RV "Tridens"

(d) UK: plaice (mean numbers per km towed for 4m beam trawl) Southern North Sea (IVc)

(e) UK: plaice ($N \cdot hr^{-1/8m}$ beam trawl) Eastern English Channel (VIId)

(g) UK: plaice (mean numbers per km towed for 4m beam trawl) Bristol Channel (VIIIf)

(h) UK: plaice (mean numbers per km towed for 4m beam trawl) Eastern Irish Sea (VIIa)

Annex 6: Population abundance indices for sole and plaice, in-shore surveys

Annex 6.1: Indices from the D(Y)FS inshore beam trawl surveys.

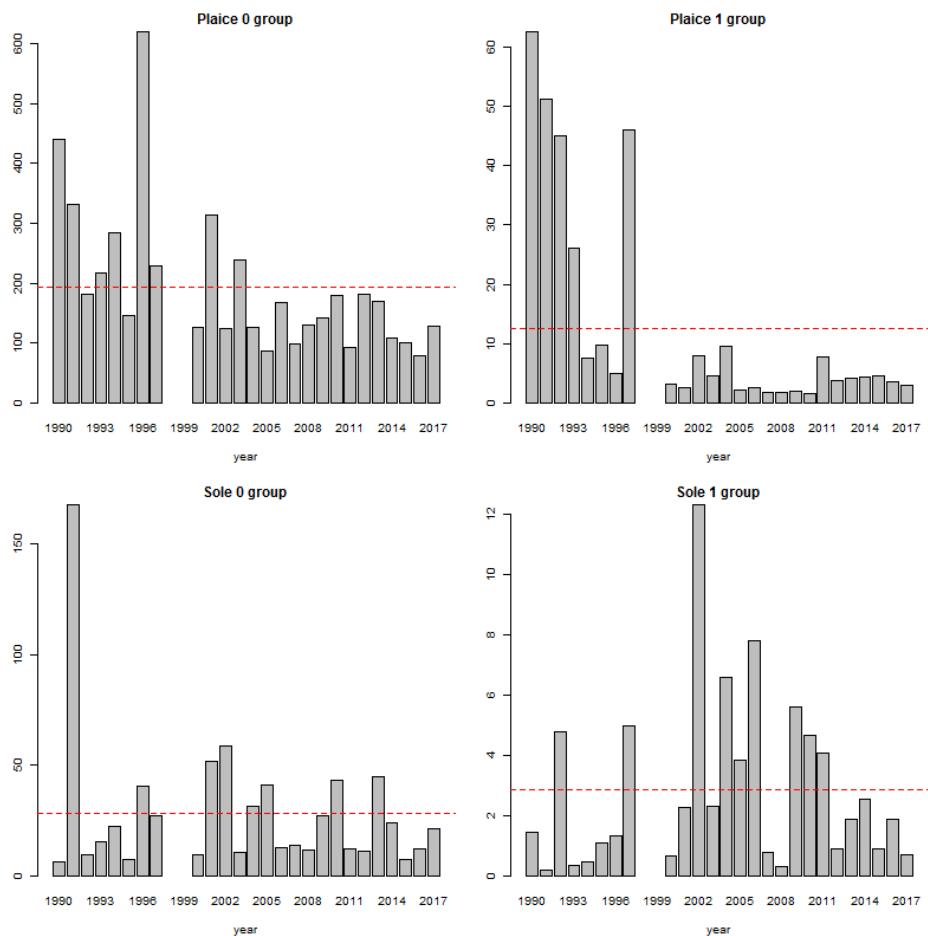

Figure 5.1.2.1. Combined inshore indices for 0 and 1 group plaice and sole. The horizontal line is the long-term mean for the period presented. The indices were declared to be invalid in 1998 and 1999, due to insufficient coverage of the Dutch survey area and are not displayed.

Annex 6.2: Indices from SNS inshore beam trawl survey

Annex 8: Survey summary sheet

Survey summary sheet

Survey, country	Area coverage	Running since	Methodology described in	Information to assessment WG	Data availability	Comments on 2017 survey	Data collected
Beam Trawl Survey, Belgium	Southwestern North Sea, figure 8.1	1992	WGBEAM beam trawl survey manual (update in progress)	WGNSSK: Pleuronectes platessa (ple.27.420), indices by age group, age 1-10+ WGEF: elasmobranch species, CPUE per species per haul WGML: litter information per haul	Unaggregated data: datras.ices.dk Density plots per species: http://ecosystemdata.ices.dk/map/	The BTS_BEL was carried out from 28/08-8/09/2018 with RV Belgica. The meteorological conditions were favourable, and there were little technical issues. (nothing that jeopardized the outcome of the survey). 57 out of 62 stations were completed successfully. Two stations (37 & 38) could not be fished due to diplomatic clearance that was not granted in French territorial waters. Three stations (19, 20 and 72) were cancelled due to the risk of collision with static fishing gear. From this year onwards the number of otoliths collected per cm size class per ICES Statistical Rectangle for cod, brill, turbot, plaice and sole was reduced from 5 to 3.	Fish species: all species Fish length: all species, elasmobranch by sex Fish weight: sample weight per species, elasmobranch by sex Fish biological data: individual weight, length, sex, yearclass for plaice, sole, cod, turbot, brill Benthos: all species, numbers and total weight per species per haul. <i>Seppia sp.</i> , <i>Loligo vulgaris</i> , <i>Cancer pagurus</i> , <i>Nephrops norvegicus</i> and <i>Homarus gammarus</i> length measurements. Anthozoa, Bryozoa, Hydrozoa and Porifera only presence absence. Marine litter: all hauls CTD: continuous profile Other: /
Beam Trawl Survey, Germany	German Bight (North Sea), figure 8.2	1991	WGBEAM beam trawl survey manual (update in progress)	WGNSSK: Limanda limanda (dab.27.3a4), Pleuronectes platessa (ple.27.420 indices by age group, age 1-10+	Unaggregated data: datras.ices.dk	The BTS was carried out from 18 Aug to 04 Sept. 63 hauls were	Fish species: all species Fish length: all species; dab, plaice, elasmobranch by sex. Fish weight: sample weight per species, elasmobranch by sex

				<p>Cuckoo ray 6 7 8abd Spotted ray 7ae-h Undulate ray 7de Smooth hound Nea Lesser-spotted dogfish 7a-ce-j Greater-spotted dogfish 6 7 Blonde ray 7e Small-eyed ray 7de Thornback ray 7e Category 6 stocks Common skate 6 7a-ce-k</p>		<p>of 128 successful tows were completed out of a total of 131 planned for the survey. This comprised 80 of the 81 planned tows in the western English Channel and 48 of the 50 planned tows in the Celtic Sea. The location not sampled in the western English Channel was in stratum 11, where operations were heavily affected by both the widespread deployment of commercial static gear and the ‘foggy’ conditions encountered. The two locations not fished in the Celtic Sea were both in stratum I, and the exclusion of these locations from the survey had been pre-planned, as colleagues from the Marine Institute in Ireland had already successfully worked these locations on their associated survey. One station was invalid because the gear had to be pulled early because of a 10m “spike” in the seabed. In addition to the 4m beam trawl deployments a further 488 gear deployments were undertaken as part of the multi-discipline survey.</p>	<p>Fish weight: sample weight by species and sex for all elasmobranch species, four-spot megrim, megrim, plaice. Fish biological data: Individual weight, length, sex and maturity for all elasmobranch species, and conger eel, (cod), (haddock), (whiting), ling, hake, (monkfish), John dory, all species of gurnard, sea bass, red mullet, four-spot megrim, (megrim), (turbot), (brill), witch, (lemon sole), (plaice), (sole). Ages determined for those species highlighted by brackets. Benthos: all species, numbers and total weight per species quantified for beam trawl with blinder. Additional observations made for beam trawl without blinder captured against catch for beam trawl with blinder. Length measurements collected for cephalopods and commercial shellfish. Sentinel and non-native species weighed and counted for both beam trawls. Marine litter: all trawls CTD: average surface and bottom temperatures and salinities collected for each tow.</p>

Annex 9: Offshore Beam Trawl Survey staff exchange: ILVO participant on WMR BTS – Q3 with RV Tridens August 2017

In the context of staff exchange and standardization of survey methods a member of ILVO (Institute for Agricultural, Fisheries and Food Research, Belgium) participated in the Dutch offshore Beam Trawl Survey organized by WMR (Wageningen Marine Research, Netherlands) in ICES division 4. The observations on differences and similarities by the staff involved in this exchange should help the involved parties and WGBEAM to better understand and coordinate the surveys from an international perspective.

The Dutch Beam Trawl survey is organized by WMR institute and takes place in different parts of the North Sea with different research vessels. The Belgian observer from ILVO joined the BTS in the southern and eastern North Sea, from the Dutch Belgian boarder up to Esbjerg Denmark, in the third quarter of 2017. The survey was carried out on board of RV Tridens (**Error! Reference source not found.**) that sailed from Scheveningen from 7 to 18 Aug 2017, with a mid-survey break on 12-13 Aug in Esbjerg Denmark. The Belgian participant stayed on board the entire trip and had the chance to contribute to the processing of the catches of all 35 hauls in the first week and all 29 hauls in the second week. This experience gave her the opportunity to make a detailed comparison between the vessels and scientific and general practices on the Dutch and Belgian offshore surveys.

Objectives and survey design

Although the Dutch and Belgian offshore beam trawl surveys were originally not set up as one survey, they nowadays follow the same manual and focus primarily on the same objectives (collecting fisheries independent data for plaice, sole and some additional commercially important species) under the coordination of WGBEAM.

The Belgian BTS is carried out with RV Belgica1 (**Error! Reference source not found.**), while the Dutch BTS was done on board of RV Tridens2 (**Error! Reference source not found.**). Both surveys attempt to fish a fixed number of stations annually (quarter 3), with tows lasting 30 min (shorter if large numbers of small fish or high bycatch of benthic species or non-biological materials, but not less than 15 min) while fishing at 4 knots over the ground during daytime. Belgian BTS stations are fixed in space, whereas on the Dutch BTS a pseudo-random design is applied. In this pseudo-random design RV Tridens targets a fixed number of priority stations, strati-

Figure 9.1: RV Tridens (up) and RV Belgica (under)

fied by ICES statistical rectangle, but the positions of these stations are randomly distributed within the rectangles. The minimum distance between two hauls is set to 10 nautical miles. Although the Belgian design is fixed, during the span of the time-series, stations may have moved slightly, mainly due to obstacles such as passive fishing gear, drilling platforms, pipelines or changes in bottom type (sand sieves) that made it too dangerous to fish with the chain mats. The rationale for the new locations has been within 5 nautical miles from the original station, and on similar grounds and depth.

Survey gear and gear deployment

Due to the different origins of the two compared surveys, no standardization in gears has taken place over time. Belgium uses a commercially rigged 4 m beam trawl equipped with chain mats. The gear is trawled from the aft (Figure 9.2). The Dutch survey uses an 8 m beam trawl on each side of the vessel (Figure 9.2). The Dutch beam trawl is fitted with 8 chains, of which 4 are connected to the beam and 4 to the net. Both Belgium and the Netherlands have a 40 mm codend liner in the net. As opposed to the practice on RV Tridens, where the permanent vessel crew prepares, inspects, deploys and hauls the gear, and brings the catch to the scientists, the ILVO-crew plays an important role in all these tasks on board of RV Belgica.

In 2016 ILVO carried out a comparative fishing study to compare the differences between towing from the aft against towing from the side. The study was done in the Irish Sea with RV Cefas Endeavour and the Belgian commercial beam trawler Jasmine

Figure 9.2: RV Belgica fishing from the aft (left) and RV Tridens fishing from the side (right).

(Z.483). Fishing was carried out in the same period (during the annual UK-Q3-BTS), in the same locations, in the same direction, with a comparable speed, haul duration and gear type (i.e. beam trawl with chain mats and 40 mm codend). The catch was processed against the same protocol and results were standardized to swept-area afterwards. The study focused on sole and showed that both the catchability and composition of the catch were very comparable, implying that there is little difference between the two fishing techniques. This study helps to justify the use of different fishing vessels applying different gear deployment techniques in internationally coordinated beam trawl surveys. However, comparative studies between member states in specific survey areas and periods of the year should still be executed to account for fine scale effects of vessel and gear. This study was part of the IRIS2 project funded by EMFF (the European Maritime and Fisheries Fund).

Processing of the catch

There are several differences between RV Belgica and RV Tridens regarding vessel properties, facilities and logistics. The most important finding relevant to this type of survey was the space available on the larger Tridens, which creates the possibility for more people to sort out the catch and work on different tasks simultaneously, making the process faster. In Figure 9.3 the facilities of RV Tridens (A) and RV Belgica (B) for the sorting of the catch are compared.

On RV Tridens the catch is deposited on the conveyor belt below deck where there is

Figure 9.3: Sorting of the catch on the Dutch BTS on RV Tridens (A) and Belgian BTS on RV Belgica (B).

space for up to 6-8 people to line up along the conveyor belt and sort out the catch. Secondly, due to the automated operation of the conveyor belt the catch can be processed fast and efficiently. On RV Tridens there is also more space for the processing of the catch. A part is done on the conveyor belt such as measuring and the sorting and counting of (epi)benthos, but there is also a separate fish lab where litter and biological fish data are recorded (Figure 9.3, A). This gives the possibility to sort out larger catches, work faster and/or work in parallel, in other words getting the maximum out of the time at sea, which is considered to be a scarce resource. On RV Belgica on the other hand, there is only one small fish lab where everything needs to happen: sorting

of the catch, weighing, measuring of the fish, cutting of otoliths (Figure 9.3, B), litter, etc. This restriction in space forces the scientific crew to work in series and deal less efficiently with the valuable time at sea. Over the years, ILVO has developed a practical working scheme to make optimum use of the limited space on board of RV Belgica in order to comply with the DCF requirements.

In Figure 9.4, a comparison is made of the work flow for the collection of biological fish data on RV Tridens (Figure 9.4, A) and RV Belgica (Figure 9.4, B). On both surveys the registration of the biological fish data are done manually since there is no computer driven central system telling the user how many individuals of a certain species still need to be documented for certain parameters in a certain area. Due to the extra space on RV Tridens and the possibility to work in parallel (as described earlier), one haul can be entirely processed before the next haul comes on deck, whereas on RV Belgica the collection of biological fish data are done at night, when all fishing activity has ended.

Figure 9.4: Work flow for the collection of biological fish data on the Dutch BTS on RV Tridens (A) and Belgian BTS on RV Belgica (B).

Sampling design

Both Belgium and the Netherlands weigh and sort the entire catch for all fish species and the main commercial invertebrates, identify these organisms to the lowest taxonomic level possible and document numbers by species. In case of the Dutch BTS that deploys two nets, only starboard is entirely sorted. Catches in portside are only used for missing length classes for the collection of otoliths for aging. The Belgian BTS does not only takes numbers, but also weights by species.

The remaining fraction of benthos/epibenthos (or – in case of large catches – a ‘mixed’ subsample that is representative for the entire catch) is sorted and identified to the lowest taxonomic level possible and numbers per taxon are recorded. Again, on the Belgian BTS also weight by species is taken, except for species belonging to Anthozoa, Bryozoa, Hydrozoa and Porifera where only absence presence is recorded. When a subsample was taken, the remaining catch is weighed on the Belgian BTS. On the Dutch BTS the total volume of the catch is estimated based on the volume of the remaining baskets and that of the subsample.

On the Belgian BTS all fish species and the main commercial invertebrates are measured to the cm below (total length). Brown crab, Norwegian lobster and common lobster are measured to 0.5 cm below by sex. The Netherlands does the same, but implements a finer resolution of 1 mm for cuttlefish, squid, brown crab, Norwegian lobster, common lobster, spiny lobster, Maja spider crab and king crab. Subsampling may occur on both the Belgian and Dutch survey when numbers of a certain species are extremely high. The subsample is then measured and the rest is counted.

Sampling design for the collection of otoliths may differ between BTS surveys. According to WGBEAM this might have implications if these differences are not been taken into consideration when data from different surveys are used for stock assessment. Also between the Belgian and Dutch BTS there are substantial differences. On the Belgian BTS sampling for age and sex is done for five species: cod, turbot, brill, plaice and sole. The number of otoliths taken is stratified by statistical rectangle. Usually 5 otoliths per cm class in each statistical rectangle are collected, but for budgetary reasons this number has been reduced from 5 to 3 in 2017. The Netherlands also stratify by ICES statistical rectangle and take 1-2 otoliths per cm class for sole and plaice. For flounder, brill, dab, turbot, lemon sole and cod they only collect four otoliths per cm class in each flatfish/roundfish area, which is at a larger spatial resolution than the ICES statistical rectangles. Maturity is staged for summer spawners such as lemon sole. On the Belgian BTS no maturity is staged for any of the five species, because quarter 3 is not the right period for determining maturity of these species. Stratification in the design and the minimum number of otoliths that should be collected by stratum in order to get the most complete length and age data for the use in stock assessment is open for discussion, but in itself, there is no problem that Belgium and the Netherlands have different sampling designs, as long as stock assessors are aware of these differences and take them into account when using the data.

Environmental data

The Belgian trawling gear is nowadays equipped with a CTD unit collecting continuous data (temperature, salinity, turbidity, ...) during the tows. Additionally, RV Belgica has an onboard data acquisition system (ODASIII) which continuously collects oceanographic, meteorological, navigational and other abiotic information coming from different measuring units on board of the ship. On RV Tridens the CTD is not attached to the net, but a stationary vertical CTD profile is taken before every tow.

Team Structure

Team structures and the whereabouts of team members on the Dutch and Belgian BTS were very comparable. The Scientist In Charge (SIC) spends most of his/hers time in the fish lab where he/she takes the coordinating task of desk master. From the fish lab he/she keeps in touch with the vessel's captain and/or skipper(s) at all time. For Belgium one of the two skippers is a full time ILVO employee who deploys the fishing gear, while on RV Tridens the captain takes the responsibility for the deployment of the fishing gear.

The scientific team on the Dutch BTS was smaller than the Belgian team in 2017. On the Dutch BTS five scientists were active in the fish lab: one person measuring, one person sorting the benthos, and two persons collecting the biological fish data. A last person was responsible for putting all data in the computer system in the dry lab. Before each taking his/hers own task everyone helps with the sorting of the catch. In contrast with the Belgian survey, on RV Tridens it is common that also crew members help with the sorting of the catch. On the Belgica crew members only assist with the operation of winches, all other tasks such as taking in the gear, releasing the catch and sorting of the catch is all done by ILVO employees. Next on the Belgian BTS, two people operate the digital measuring boards for length measurements. Two to three scientists help with the sorting of the epibenthos sample and one other person weighs the remaining catch. In this regard both surveys are comparable since every person has his/hers own responsibilities.

The collection of biological fish data are less similar between the two surveys. On RV Belgica this is done in the evenings after all fishing activities have stopped. Again everyone has his/hers specific responsibilities: one person takes the sex of the fish, another weights and measures with the digital measuring board, and a third person collects the otoliths (see Figure 9.3 B). On the Dutch BTS this is done in between tows and only one person carries out all the different steps of determining sex, measuring, weighing and cutting the otoliths (see Figure 9.3 A).

Conclusion

The main differences between the Dutch and Belgian offshore BTS observed were vessel dimensions, survey design and gear deployment, automation of catch sorting and sampling, and the sampling design for biological fish data. The large amount of space on board of RV Tridens is an asset for efficient catch processing, whereas on RV Belgica space is rather a limiting factor. On the Dutch BTS lengths and individual weights are still recorded manually, as opposed to the Belgian BTS where this is done automatically through the digital measuring board, permitting less errors to occur.

Although some differences between the two compared surveys are listed above, they obviously have a lot in common due to their similar objectives, joint manual and the common coordination by WGBEAM. The differences in vessel dimensions and approach are not considered to lead to differences in relevance and applicability of the data collected.

Annex 10: WGBEAM 2018 Working Document (WD1)

Epibenthic community data from the Dutch offshore beam trawl surveys

WD1 to WGBEAM 2018

Sven Kupschus and Ingeborg de Boois

Background:

WKPIMP 2016 requested that WGBEAM 'Compare the macro-epibenthos catches in species composition and quantity of at least IBTS Q3 and Beam Trawl Survey catches'. WGBEAM was unable to fully complete the request as the IBTS Q3 data on epibenthos is not available on datras. Instead the WG evaluated the epibenthic community structure from the Dutch BTS surveys carried out on Tridens and ISIS with those of the fish communities of both the beam trawl and GOV (IBTS Q1 and Q3 combined). Haul locations and number of hauls differ between these surveys so for the purposes of this analysis the data were aggregated by ICES-rectangle and year combinations to enable comparisons. The analysis was limited to the rectangle-year combinations where all three data types were available on datras.

WGBEAM concluded:

General community structure is highly consistent between epibenthic communities and fish communities as sampled simultaneously by the beam trawl and independently in the GOV.

For the three communities examined patterns are spatio-temporally very consistent and at the very least do not suggest large changes over time. Spatial differences are much more important than changes over time, suggesting that without considering spatial effects comparisons between years is unlikely to detect changes of the magnitude contained in the time-series.

Observed differences in the spatial extent of different clusters are largely artefacts of the clustering method chosen. Ordination analysis suggest that spatial changes are gradual and clustering responds differently to these changes. Correlation between the correspondence analysis eigenvectors is highly significant across the different communities with beam trawl and GOV fish communities having an $r^2=0.934$ on the first axes, and both fish communities correlating with epibenthic communities (r^2 0.88 and 0.87 for GOV and beam trawls respectively).

Spatial scales of community variability are significantly larger than the inter station distances, and correlation between communities sampled by different surveys (not the same location) suggest that habitats are either homogenous or a highly consistent mosaic of different communities at spatial scales much smaller than those of the trawls. In any case possible scales of marine spatial management are significantly larger than the scales of sampling.

The working group concludes that epibenthic sampling from gears designed for fishing can be indicative of epibenthic species at scales relevant to management and that combining epibenthic catches from the North Sea beam trawl surveys for integrated analysis with fish catches should be possible at least at the general level. Further analysis is necessary to investigate the utility for more specific purposes.

Approach and Results:

There is no single one appropriate method to evaluate the utility of the quantitative epibenthic information collected by the Dutch beam trawl survey. Choice of method is

ultimately dependent on the objectives of a specific analysis. To ascertain a general picture, qualitative (classification) and quantitative (ordination) multivariate techniques were used to attain a general picture of the systematic variance components in the data.

Epibenthic data were screened for taxonomic consistency with regards to identification. Where identification was questionable or recording at the taxonomic level inconsistent further data collectors were requested to provide additional information to ensure consistency. Generally, the information is evaluated at the species level with only a relatively small number of groups (hydrozoans and worms being excluded entirely) and about 10 taxa being aggregated at the genus level. Colonial species are evaluated as presence absence so are likely to be underrepresented in this analysis. This resulted in 86 epibenthic taxonomic groups over 16 years (2002-2017). Data on fish abundances by haul for both the BTS survey and the IBTS survey (both quarters combined) were not screened in detail for taxonomic consistency due to time constraints but given the greater focus on these taxa it is expected that recording is more consistent.

All three data types were aggregated at the ICES rectangle and year combination level and evaluation restricted to those combinations for which all three data types were available. IBTS data are generally more extensive so that mostly data are restricted by the availability of beam trawl data. The species matrix was log-transformed to reduce the weighting of the dominant species. Only the 60 most abundant species of each data type were used. Abundance by rectangle and year was log-transformed.

Cluster analysis:

Clustering was applied to the Bray–Curtis distance matrix and aggregated using Ward’s method. The number of clusters chosen is arbitrary here 12 spatially consistent clusters are displayed, purely for the ease of recognition in plots. Figure 1 represents the dendrogram of the epibenthic cluster analysis (fish dendrograms not shown for brevity), with Figure 2 providing some information as to the species abundances that are characteristic of the various clusters. For the most part differences between clusters are based on changes in the relative abundance of species between clusters as opposed to differences in the presence and absence of species. Figure 3 demonstrates the temporal consistency of the clusters suggesting there have been few changes in the epibenthic communities at the ecosystem level, at the very least those differences are smaller than the differences between areas.

Given the qualitative results of the classification methods, quantitative comparison between the spatial and temporal variability of the three different sampling types are difficult. Never-the-less the two fish communities (BTS; Figure 4 and IBTS; Figure 5) indicate very much the same spatial patterns and largely a lack of temporal variability just like the epibenthic data. Differences of the areas of transition between communities are assessed differently in the communities, but the overall spatial structure is highly consistent.

Ordination:

One way to investigate the community structures more quantitatively is ordination. Catches should ideally be standardized for swept-area, however there are only a few stations where this is an issue so in this quick analysis this was ignored and catches rather than CPUE used. The analysis indicates that rather than discrete communities of epibenthic species there are gradients in species distribution, with the identified clusters representing somewhat arbitrary breaks in these gradients. The specific location of these breaks depends on the interaction between the clustering methodology

and the characteristics of the data. Therefore, the described differences in the location of communities between the different datasets is mostly an artefact of the clustering method rather than specific differences between communities.

A correspondence analysis was performed on each of the three separate datasets and the correlation between each pair was investigated. Figure 6-8 show the comparative plots of the site (ICES rectangle year combinations) scores, IBTS fish versus BTS epibenthos, BTS fish versus BTS epibenthos and IBTS fish versus BTS fish. Symbols are coloured by the classification associated with the sample and show generally that the ordination methods capture the same community information as the cluster analysis (i.e. clusters show significant separation in the ordination). Correlation coefficients for each of the axes are shown in the graphs. They are generally very high for the first axes with subsequent axes still being highly significantly correlated in all cases, but the magnitude of the fit is more variable and values generally lower. Even where correlation is poorer clusters still remain significantly grouped in the ordination.

Figure 2: Dendrogram of the epibenthic clusters based on Bray-Curtis dissimilarity. The primary split (clusters 10-12 versus 1-9) corresponds spatially to a northwest / southeast split in the North Sea ecosystem. Colours correspond to the colours used in the spatial plot Figure 3)
