The ICES/NAFO W orking Group on Harp and Hooded Seals (WGHARP) met during 2630 September 2016 Copenhagen, Denmark. The WG received presentations related to catch and abundance estimates, and ongoing research of White Sea/Barents Sea, Greenland Sea and Northwest Atlantic Ocean harp and hooded seal stocks. The WG concluded their meeting on 30 September 2016. In attendance were scientists representing Canada (2), Greenland (1), Norway (3), UK (1), USA (1), and Russia (2), as well as observers from NAMMCO (1) and Denmark (1) (Annex 1).

Reported catches for harp seals in 2016 were 1442, 28, and 146614 animals from the Greenland Sea, White Sea, and NW Atlantic populations respectively. Total hooded seal catches were 18 pups from the NE Atlantic and 1856 animals from the NW Atlantic population including Greenland harvests.

Current research on the Greenland Sea harp seal has focused on the animal welfare aspects of different killing methods. Data collection has ended and analyses are underway. Software-based seal detection methodology hasbeen developed. Evaluating the seal detection scheme using a validation dataset, an accuracy of $99.7 \%$ was obtained. False positives occur and therefore a semi-automatic approach was implemented, where a human reader checks if detections correspond to actual seal pups, and can modify the results if necessary.
No new survey information w as available for any stock. For the Greenland Sea harp seal population a population model estimates a 2017 abundance of 543800 ( $95 \% \mathrm{Cl}$ : 366500719 400) 1+ animals and 106500 ( $95 \%$ CI: 76500136400 ) pups. The total population estimate is 650300 ( $95 \% \mathrm{CI}: 471200829300$ ) seals. Using current catchlevels, the model projects an increase in the $1+$ population of $58 \%$ over the next 15 years. The equilibrium catch level (which maintains constant populationsize) is $21500(100 \% 1+$ animals). If pups are hunted, two pups balance one $1+$ animal. A catch of 26000 animals $(100 \% 1+)$ will reduce the population, but with a 0.8 probability that the population remains above N70 over a 15 year period. Catch estimates are lower than previous advice due to changes in fecundity rates used in the projection. Because future fecundity rates are not known, an average of the fecundity rates observed over the past decade was used in the projections. This resulted in an average fecundity rate of 0.84 , which is lower than the rate observed in 2016 ( $\mathrm{F}=0.91$ )

In the White Sea, poor ice conditions were observed in 2015 and 2016. There was no suitable ice for pupping inside the White Sea, but seals with pups were observed on the ice at the entrance to the White Sea. Ice also accumulated in the southeastern Barents Sea. If poor ice conditions are encountered in the White Sea during 2017, the southeast Barents Sea will be searched to see if pupping also occurs in this area.

The model estimates of abundance for White Sea harp seals in 2017 is 1197000 (95\% CI: 10428001351 200) 1+ animals and $211000(185100-236900)$ pups. Total estimate is 1408000 ( $95 \%$ CI: 12516801564320 ). The last reproductive rates available are based on data from 2006. The WG was concerned about using the last observed fecundity rate of 0.84 in future projections. Instead, an average of fecundity rates observed over the last 10 years, w as used in the projections $\left(\mathrm{F}_{\text {future }}=0.76\right)$. The harp seal population in the Barents Sea/White Sea is considered data poor because of the time elapsed since the last series of reproductive samples were obtained. For this reason, the catch option to reduce the population to N 70 w as not examined for this stock. Because the stock is

Data Poor, this means that the Potential Biological Removal (PBR) approach for estimating catch quotas should be considered. How ever, in simulations based on the population model, using this approach resulted in a projected population decline of $25 \%$ over the next 15 years. The WG concluded that the PBR catchlevel w as not suitable for providing advice on future catch quotas and recommended that equilibrium catch levels be used. The equilibrium catch level is 10090 seals ( $100 \% 1+$ animals). The model indicates an increase of $12 \%$ for the $1+$ population over 15 years with no catch.

For Northwest Atlantic harp seals a population model was used to examine changes in the size of the population between 1952 and 2014, and then extrapolated into the future to examine the effect of different harvest simulations on the modelled population. The working group examined the level of catches necessary to reduce the harp seal population to 6.8 million or 5.4 million animals assuming catches consisted of $90 \%$ Young of the Year (YOY) or 50\% YOY, and occurred over different time periods (5, 10 ,and 15 years). Then, once the herd was reduced, the level of catch possible that would maintain a $95 \%$ probability of remaining above the Limit Reference Level. The impacts of the different catch options on the projected population were tested under two scenarios. The first scenario (Model A) assumed that reproductive rates and Greenland catches were similar to that seen over the past 10 years. The second scenario, referred to as Model B, assumed that both future reproductive rates and Greenland catchesbehave in a density-dependent manner. The predicted changes in the population trajectory were affected very strongly by the age composition of the harvest used to reduce the population, the speed at which the reduction was achieved and on model assumptions concerning density-dependence.
The results of the modelling exercise indicated that more animals would need to be removed if the population reduction was to be achieved rapidly, or with a harvest comprised primarily of YOY. Under Model A, once the target level w as achieved, the catch levels that would ensure a $95 \%$ probability of remaining above the Critical Reference Limit were much lower than the harvest levels allowable during the reduction phase. Under Model B, the numbers of animals needed to be removed to achieve the reduction target of 6.8 million animals, were similar to the numbers of animals needed to reduce the population to the same level, but under Model A. How ever, with Model $B$ and a reduction target of 6.8 million animals, much higher harvests w ere allow ed over the 15 years following the reduction due to the increased reproductive rates and reduced Greenland catch that were assumed. Under all scenarios, the uncertainty associated with estimates of population size increased considerably as time since the last survey also increased. The objective of the exercise was to have a $95 \%$ likelihood of remaining above the limit reference point ( 2.4 million) rather than to maintain the population at the reduction target level. As a result, in some scenarios, high catches could be taken after the initial reduction. How ever, these would result in a continued reduction in the population. If the management objective had been to maintain the population at the reduction target level, the 'post reduction' catches would have been much smaller.

These simulation results are very sensitive to model assumptions and should be considered for illustration only.

The summer (June-July) diet of Greenland Sea hooded seals was studied in the West Ice in 2008 and 2010, based on analysis of gastrointestinal contents of 179 animals obtained in dedicated surveys. Polar cod dominated the diet. The im portance of the squid Gonatus fabricii w as lower in this study compared with previous hooded sealstudies in the area.

The estimated 2017 abundance of Greenland Sea hooded seals was $668601+$ animals ( $95 \%$ CI: $45860-87860$ ) and 13600 (925017950) pups. The estimated total 2017 population is 80460 ( $95 \%$ CI: 59020101900 ). All modelruns indicate a population currently well below the Limit Reference Level. Following the precautionary approach framew ork developed by WGHARP, no catches should be taken from this population. Previously, ICES recommended that no harvest of Greenland Sea hooded seals should be permitted, with the exception of catches for scientific purposes. Eighteen animals, including 10 pups were taken for scientific purposes by Norway in 2016.

## Opening of the meeting

The ICES/NAFO W orking Group (WG) on Harp and Hooded Seals (WGHARP) met during 2630 September, 2016 at ICES headquarters, in Copenhagen, Denmark. The WG received presentations related to estimates of catch, abundance, biological parameters and current research of relevance to White Sea/BarentsSea, Greenland Sea and Northwest Atlantic Ocean harp and hooded seal stocks. The WG provided catch options for the West Ice/Greenland Sea harp and hooded seals and White Sea/Barents Sea harp seals. The WG also discussed the implications of possible management objectives proposed for the Northwest Atlantic harp seal population. In attendance were scientists from Canada (2), Greenland (1), Norway (3), UK (1), USA (1) NAMMCO (1), Denmark (1), and Russia (2), (Annex 1).

## 3 Adoption of the agenda

The agenda for the meeting, as shown in Annex 2, w as adopted at the opening of the meeting on 26 September 2016.

WGHARP - Group on Harp and Hooded Seals
The ICES/NAFO/NAMMCO Working Group on Harp and Hooded Seals (WGHARP) chaired by Mike Hammill, Canada, will meet in ICES HQ, Copenhagen, Denmark, 26-30 September, 2016 to:

## Harp and hooded seals: Northeast Atlantic stocks:

a ) Address the special request from Norway on the Management of Harp and Hooded Seal stocks in the Northeast Atlantic by assessing the status and harvest potential of the harp seal stocks in the Greenland Sea and the White Sea/Barents Sea, and of the hooded seal stock in the Greenland Sea. ICES should also assess the impact on the harp seal stocks in the Greenland Sea and the White Sea/Barents Sea of an annual harvest of:
i) current harvest levels;
ii) sustainable catches (defined as the fixed annual catches that stabilizes the future $1+$ population);
iii ) catches that would reduce the population over a 15-year period in such a manner that it would remain above a level of $70 \%$ of the maximum population size, determined from population modelling, with $80 \%$ probability.
b ) Evaluate new model developments and comparisons with the old assessment model

## Harp seals: Northwest Atlantic stock:

c ) Explore the impact of proposed harvest strategies that would maintain the North Atlantic harp seal population at a precautionary level of a PA framework, using the Canadian levels as a case study, and that would have a low risk of decreasing below the critical level.

Note - The terms of reference regarding item $b$ were not addressed at the meeting.

### 5.1 Stock Identity

No new information

### 5.2 The Greenland Sea Stock

### 5.2.1 Information on recent $c$ atches and regulatory measures

## Catches

Based on advice from WGHARP (ICES 2013) the 2015-2016 TAC for harp seals in the Greenland Sea was set at 21270 1+animals (where 2 pups balanced one $1+$ animal), i.e. the estimated removal level that would reduce the population by $30 \%$ to N70 over the next 10 year period (see ICES 2013)(Annex 8, Table1). The total removals of Greenland Sea harp seals in 1946-2016 are shown in Annex 7, Table 1. No Russian vessels have hunted in this area since 1994. Total catches (performed by one vessel each year) of harp seals were 2237 (including 2,144 pups) in 2015 and 1442 (including 426 pups) in 2016 (Annex 7, Table 1).

The group was informed, that up to the 2014 season, Norwegian seal hunts were subsidized by the Norwegian government. For the 2015 sea son these subsidies were completely removed. They were reinstated in 2016, however on a considerably lower scale than in previous years.

### 5.2.2 Current research

## Sealing methods

A project including collection of material to assess efficiency and animal welfare issues in the Norwegian commercial sealhunt was started in 2013, continued in 2014 and field efforts ended after the commercial harp seal hunt in the Greenland Sea in April/May 2015. Analyses of the collected material are in progress.

## Identification of seals on digital imagery

Pup production of harp and hooded seals are based primarily on photographic surveys, which are time-consuming to analyse manually. Software-based detection methodology using artificial intelligence (deep learning) has been developed as a collaboration between the Norwegian Computing Centre and Institute of Marine Research, Norway and Fisheries and Oceans, Canada. Deep learning has revolutionized image analysis over the last four years in terms of its ability to extract content and information from images. The developed deeplearning scheme is based on a deep convolutional neural network and initial tests of the proposed deep learning based seal detection scheme shows that seals can be detected with a very high accuracy. By evaluating the proposed method on a validation dataset, an accuracy of $99.7 \% \mathrm{w}$ as obtained. False positives occur and therefore a semi-automatic approach was implemented, where a reader may evaluate the detected seal pups and modify the results if necessary.

A new method for estimating the pup production using a geospatial point process is under development. If successful, this may lead to improvements in estimates of variance associated with the pup abundance surveys.

### 5.2.3 Biological parameters

Mean age of maturity (MAM) was estimated at $6.15 \pm 0.6$ years for a sample of 197 Greenland Sea harp seals collected early in the moulting period in 2014 (Frie SEA246). This estimate is not significantly different from the long term average of 5.6 y ears estimated for the period 1964-1990, but is significantly different from the 2009 estimate ( 7.6 years). The ovary-based pregnancy rate for the 2014 sample was $0.91 \pm 0.02$, which is significantly higher than estimates for the period 1991-2009, but similar tovalues from 1964 and 1978. The estimated MAM for 2014 was only 0.5 years lower than the mean age of primiparity (MAP) estimated for the same sample, due to near absence of first time ovulators. Fur ther comparisons of MAM and MAP for Greenland Sea harp seals suggest that first time ovulators were poorly represented in samples from 1990, 1991 and 2009. The difference between MAM and MAP for these samples was close to 1 year implying an unrealistically high pregnancy rate of $100 \%$ for first time ovulators. In comparison, the difference between MAM and MAP for samples collected in 1959-64, $1978,1987,1990$ was 1.5 years. The timing of sampling in 2009 and 2014 was similar to, or slightly later than in 1978, suggesting that a seasonal delay of ovulation in young females is not the main reason for the low occurrence of first time ovulators in the more recent Greenland Sea samples. Mark-recapture analyses for the Greenland Sea (Øien and Øritsland, 1995) have previously suggested temporal emigration of some cohorts up to the time of first pupping, which could explain the absence of the first time ovulators in the 2014 Greenland Sea sample.

### 5.2.4 Population assessment

No new survey information is available. The next survey is planned for March 2018.
The current abundance of harp seals in the Greenland Sea was estimated using a population dy namics model that incorporates historical catch records, historical fecundity rates, and age specific proportions of mature females. The model is fitted to independent estimates of pup production (Øigard and Haug SEA240). It is a deterministic agestructured population dynamics model with 3 unknown parameters (pup mortality, mortality of 1 year and older seals, initial population size). This model is the same as used previously by the WG to provide advice for this stock.

## Model Input

Tw o types of reproductive data are used: information on the proportion of females that are mature at a given age (i.e. maturity ogive) and the proportion of mature females that are pregnant at a given year (i.e. fecundity rate). Historical data on the maturity curve are sparse, consisting of only three curves (Table1). One curve is from the period 19591990, one is from 2009 and the last one is from 2014. For the periods with missing data (19902009 and 2009-2014), a linear transition between the available maturity curves is assumed. Figure 1 shows the maturity curves from Table 1, along with the linear interpolation between the curves in years with missing data.

Table 1. Estimates of proportions of mature females ( $p_{\mathrm{i}, \mathrm{t}}$ ). The $P_{1}$ estimates are from the period 1950 - 1990 (ICES, 2009), the $P_{2}$ estimates are from 2009 (ICES, 2011) and the $P_{3}$ estimates are from 2014 (Frie, SEA246).

| AGE | $\mathbf{1}$ | $\mathbf{2}$ | $\mathbf{3}$ | $\mathbf{4}$ | $\mathbf{5}$ | $\mathbf{6}$ | $\mathbf{7}$ | $\mathbf{8}$ | $\mathbf{9}$ | $\mathbf{1 0}$ | $\mathbf{1 1}$ | $\mathbf{1 2}$ | $\mathbf{1 3}$ |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |

Figure 1. Proportion of mature females and the interpolated values for years without data among Greenland Sea harp seals in three periods. Values are taken from Table 1.

The model uses historical values of the fecundity rates $F$ rates that are obtained through sampling during the commercialhunt (Table 2). Data are available from a Russian long term dataset (19591991) (Frie et al., 2003) as well as Norwegian data for 2008 and 2009 (ICES, 2011). A new pregnancy rate for 2014 w as presented (Frie, SEA246). The long term dataset on pregnancy rates relies on the assumption that pregnancy in the previous cycle can be estimated based on the presence/absence of a large luteinised Corpus albicans (LCA) in the ovaries of females sampled in April-June (ICES, 2009). A similar approach has previously been used for estimation of pregnancy rates of ringed seals (Stirling, 2005). In periods where data are missing, a linear transition between estimates w as assumed. Figure 2 shows the available historical pregnancy rates and the interpolated values for years with missing data. As opposed tobeing part of the data to which the model is fit by maximum likelihood, these rates are treated as fixed values (with no variance) by the population dynamics model.

Table 2. Estimates of proportion of Greenland Sea harp seal females giving birth. It is assumed that the fecundity rate and pregnancy rate are the same. Data from (ICES, 2011) and (Frie, SEA246).

| YeAR | FECUNDITY RATE | STANDARD DEVIATION |
| :---: | :---: | :---: |
| 1964 | 0.92 | 0.04 |
| 1978 | 0.88 | 0.03 |
| 1987 | 0.78 | 0.03 |
| 1990 | 0.86 | 0.04 |
| 1991 | 0.83 | 0.05 |
| 2008 | 0.80 | 0.06 |
| 2009 | 0.81 | 0.03 |
| 2014 | 0.91 | 0.03 |

Figure 2. Historical fecundity rates $F$ of mature females Greenland Sea female harp seals and the interpolated values for years with missing data. Values are taken from Table 2.

Pup production estimates are available from mark-recapture estimates (1983-1991) and aerial surveys conducted (20022012) (Table 3). Catch levels for the period 1946-2016 are listed in Appendix 7, Table 1).

Table 3. Estimates of Greenland Sea harp seal pup production (ICES 2011, Øigård et al., 2010; Øigård et al., 2014a; ICES 2013). The data from 19831991 are mark--recapture estimates; those from 2002, 2007 and 2012 are from aerial surveys.

| YEAR | ESTIMATED NUMBER OF PUPS | COEFFICIENT OF VARIATION. |
| :--- | :--- | :--- |
| 1983 | 58539 | 0.104 |
| 1984 | 103250 | 0.147 |
| 1985 | 111084 | 0.199 |
| 1987 | 49970 | 0.076 |
| 1988 | 58697 | 0.184 |
| 1989 | 110614 | 0.077 |
| 1990 | 55625 | 0.077 |
| 1991 | 67271 | 0.082 |
| 2002 | 98500 | 0.179 |
| 2007 | 110530 | 0.250 |
| 2012 | 89590 | 0.137 |

## Population model

The population model used to assess the abundance for the Greenland Sea harp seal population is a deterministic age-structured population dynamics model (Øigard and Haug SEA240).

For initiation of the model it is assumed that the population had a stable age structure in year $y_{0}=1945$, i.e.

$$
\begin{align*}
& N_{i, y_{0}}=N_{y_{0}} s_{1+}^{i}\left(1 \quad s_{1+}\right), i=1, \ldots, A-1,  \tag{1}\\
& N_{A, y_{0}}=N_{y_{0}} s_{1+}^{A 1} \tag{2}
\end{align*}
$$

Here $A$ is the maximum age group containing seals aged $A$ and higher, set to 20 years (ICES, 2013), and $N_{y_{0}}$ is the estimated initial population size in the first year (yo). The model is parameterized by the natural mortalities $M_{0}$ and $M_{1+}$ for the pups and seals 1 year and older seals, respectively. These mortalities determine the survival probabilities $s_{0}=\exp \left(-M_{0}\right)$ and $s_{1+}=\exp \left(-M_{1+}\right)$.

The model has the following set of recursion equations:

$$
\begin{align*}
& N_{1, y}=\left(\begin{array}{ll}
N_{0, y 1} & \left.C_{0, y 1}\right)
\end{array}\right) s_{0}, \\
& N_{a, y}=\left(\begin{array}{ll}
N_{a 1, y 1} & C_{a 1, y 1}
\end{array}\right) s_{1+}, \quad a=2, \quad, A \quad 1,  \tag{3}\\
& N_{A, y}=\left(\begin{array}{lll}
N_{A 1, y 1} & C_{A 1, y 1}
\end{array}\right)+\left(\begin{array}{ll}
N_{A, y 1} & C_{A, y 1}
\end{array}\right) s_{1+} .
\end{align*}
$$

Data are not available to estimate age-specific mortality rates. Therefore it is assumed that the mortality rates are constant across ages within the $1+$ group. The $C_{a y}$ are the age-specific catch numbers, but catch records are available only as the number of pups and number of $1+$ seals caught. To obtain $C_{a, y}$ in (3) we assume that the age-distribution in the catch follows the estimated age distribution of the population (Skaug etal., 2007):

$$
\begin{equation*}
C_{a, y}=C_{1+y} \frac{N_{a, y}}{N_{1+, y}}, \quad a=1, \quad, A, \tag{4}
\end{equation*}
$$

where $N_{1+, y}={ }_{y=1}^{A} N_{a, y}$, with $N_{a, y}$ being the number of individuals at age $a$ in year $y$. The modelled pup abundance is given by

$$
\begin{equation*}
N_{0, y}={\frac{F_{y}}{2}}_{a=1}^{A} p_{a, y} N_{a, y}, \tag{5}
\end{equation*}
$$

where $N_{a, y} / 2$ is the number of females at age $a$ in year $y, F_{y}$ is the fecundity rate and $p_{a, y}$ are the age specific proportions of mature females in year $y$.

Assuming normality for the pup production counts, their contribution to the log-likelihood function is

$$
\begin{equation*}
\sum_{t}-\log \left(c v_{0, y}\right)-\frac{1}{2} \frac{\left(N_{0, y}-n_{0, y}\right)^{2}}{c v_{0, y} n_{0, y}} \tag{6}
\end{equation*}
$$

where $n_{0, y}$ and $c v_{0, y}$ denotes the survey pup production count and cor responding coefficient of variation (CV) for year $y$, respectively (Table 3).

The model calculates a coefficient $D_{1+}$, which describes the increase or decrease in the $1+$ population trajectory over a 15 -year period,

$$
\begin{equation*}
D_{1+}=\frac{N_{1+, 2032}}{N_{1+, 2017}} . \tag{7}
\end{equation*}
$$

The coefficient is used for finding the equilibrium catch levels. The equilibrium catch level is defined as the constant catch level that results in the population size in 2032 being the same as in 2017 , i.e. the catch level that gives $D_{1^{+}}=1$.

The population dynamics model is a Bayesian type model as priors are imposed on the parameters. A vague normal prior is assumed for the initial population size $N_{y_{0}}$ and a truncated normal prior for both the pup mortality $M_{0}$ and the mortality for the $1+$ group $M_{1+}$ (Table 4).

The combined likelihood-contributions for these priors are

$$
\begin{equation*}
\frac{1}{2}(\mathbf{b}-\mathbf{m})^{\mathrm{T}} \quad{ }^{1}(\mathbf{b}-\mathbf{m}) \quad \frac{1}{2} \ln | | \frac{3}{2} \ln (2) \tag{8}
\end{equation*}
$$

where $\mathbf{b}=\left(N_{0, y}, M_{0}, M_{1}\right)^{\mathbf{T}}$ is a vector containing the parameters estimated by the model, T denotes the vector transpose, $\mathbf{m}$ is a vector containing the respective mean values of the normal priors for the parameters in $\mathbf{b}$, and $\Sigma$ is a diagonal matrix $w$ ith the variance of the respective prior distributions on the diagonal. The mean of the prior for $M_{0}$ was set at three times the mean of $M_{1+}$.

All parameter estimates are found by minimizing the likelihood function using the statistical software ADModel Builder (Fournier et al., 2012). ADModel Builder calculates standard er rors (SE) for the model parameters, as well as the derived parameters such as present population size and $D$. It uses a quasi-Newton optimization algorithm with bounds on the parameters, and calculates estimates of standard errors of model parameter using the "delta-method" (Skaug et al., 2007). The catch data enter the model through Eq. (3), but do not contribute to the objective function. Handling of data and visualizations were done in R (R Core Team, 2015).

The estimated population sizes and parameters used in the model, along with the normal priors, used are presented in Table 4 . The model trajectory indicates a substantial increase in the population abundance from the 1970s to the present (Figure 3). The model estimates are stable for various choices of initial values. Although the priors for $\mathrm{M}_{0}$, and $\mathrm{M}_{1+}$ are relatively non-informative, increasing the mean of the prior to 0.3 and 0.1 , respectively, caused a $0.1 \%$ change in the total population estimate. Due to the limited data available, mortality cannot be estimated independently and the model estimates of $\mathrm{M}_{0}$ and $\mathrm{M}_{1+}$ are highly correlated ( -0.95 ).

The model estimates a 2017 abundance of 543800 ( $95 \% \mathrm{CI}: 366500719$ 400) 1+ animals and 106500 ( $95 \%$ CI: 76500136400 ) pups. Total estimate is 650300 ( $95 \% \mathrm{CI}: 471200829$ 300) seals.

Table 4: Greenland Sea harp seals: Estimated and derived mean values and standard deviations of the parameters used in the model. Priors used are shown in brackets. $\mathrm{N}_{\text {max }}$ is the historically largest total population estimated by the model, $\mathrm{N}_{70}$ is $70 \%$ of $\mathrm{N}_{\text {max }}, \mathrm{N}_{\mathrm{lim}}$ is $30 \%$ of $\mathrm{N}_{\text {max }}$, and $\mathrm{N}_{\text {min }}$ is the estimated population size using 20th percentile of the lognormal distribution.

Figure 3. Greenland Sea harp seals: Modelled population trajectories for pups and total population (full lines), $\mathbf{9 5 \%}$ confidence intervals. Future projections are illustrated by confidence bands. $\mathbf{N}_{70}$, $\mathbf{N}_{50}$, and $\mathrm{N}_{\text {lim }}$ denote the $\mathbf{7 0 \%}, 50 \%$ and $30 \%$ of the estimated maximum population size, respectively. Observed pup production estimates and $95 \%$ confidence intervals are shown in blue.

## Catch options

The most recent reproductive rates available are based on data from 2014 (Frie, SEA 246) and pup production estimates are based on data from 2012 (ICES, 2013), i.e. less than 5 years old. Based on this, the WG considers the harp seal population in the Greenland Sea as data rich and catch advice can be provided with the use of an appropriate population model. Hammill and Stenson (2010) explored the impact of extrapolating catches on our ability to monitor changes in the population given the precision and frequency of pup production surveys. They found that catches should be projected over a period of at least 15 years to determine their impact on the population. In 2013 the $W$ recommended that in future, the impact of the various catch scenarios should be explored over a 15 year period rather than 10 years used previously (ICES, 2013). The impact of various catch scenarios are therefore explored over a 15 year period. The catch scenarios are:

1 ) Current catch level (average of the catches in the period 2012-2016).
2 ) Equilibrium catches.
3 ) Catches that would reduce the population to $\mathrm{N}_{70} \mathrm{w}$ ith probability 0.8 over a 15 -year period.

Current catchlevel is defined as the average catch level of the last 5 years, i.e. the average catch level of the period 2012-2016. For pups there has been zero catch in this period, and for the $1+$ group 9 seals. The equilibrium catchlevel is defined as the (fixed) annual catch level that stabilizes the future $1+$ population under the estimated model. The proportion of pups in catch used was $0 \%$ and $80.4 \%$. Option 3 is the highest harvest level that would ensure with $80 \%$ probability that the population size does not fall below N70 over a 15 year period.

The WG was concerned about the uncertainty in the pregnancy rates and felt that using the last observed fecundity rate in the projections was not appropriate given observed historical variation. They considered that it was more appropriate to use an average of the fecundity rates observed over the past decade in projections of the population size. This is consistent with the practice used for other harp seal stocks. The fecundity rate used for projections was Ffuture $=0.84$.

The estimates for the various catch options are given in Table 5. Using current catch levels the model projects an increase in the $1+$ population of $58 \%$ over the next 15 years. The equilibrium catchlevel is $21500(100 \% 1+$ animals). If pups are hunted, two pups balance one $1+$ animal. A catchlevel of 26000 animals ( $100 \% 1+$ ) will reduce the population to $\mathrm{N}_{70}$ with an 0.8 probability that the population remains above this level over a 15 year period.

Table 5. Catch options with relative $1+$ population size ( $\mathrm{D}_{1+}$ ) in 15-years (2032) for harp seals in the Greenland Sea.

| CATCH OPTION | PROPORTION <br> PUPS IN <br> CATCHES | PUP <br> CATCH | $1+$ <br> CATCH | TOTAL <br> CATCH |  |
| :--- | :--- | :--- | :--- | :--- | :--- |
| Current level | $80.4 \%$ | 5992 | 1465 | 7456 | $1.58(1.30-1.86)$ |
| Equilibrium | $0 \%$ | 0 | 21500 | 21500 | $1.00(0.61-1.40)$ |
| Reduce to N70a) | $0 \%$ | 0 | 26000 | 26000 | $0.85(0.40-1.29)$ |

${ }^{\text {a) }}$ Catches that would reduce the population to $70 \%$ of current level with 0.8 probability over 15 years.

The available data on fecundity are limited. The population model does not consider the uncertainty in the estimated fecundity rates. Instead it treats the available data on fecundity and age specific maturity as known quantities. Therefore the confidence intervals around model projections are underestimated. The WG recommends that the model should be modified to account for the uncertainties of these reproductive data.

### 5.3 The White Sea and Barents Sea Stock

### 5.3.1 Information on recent c atches and regulatory measures

Due to a sharp decline in pup production observed after 2003, ICES $(2013,2014)$ recommended that removals be restricted to the estimated sustainable equilibrium level which was 17,400 and 19,2001+ animals (where 2 pups balanced one $1+$ animal) in 2015 and 2016, respectively. The Joint Norwegian-Russian Fisheries Commission has followed this request of which 7,000 seals of this TAC was allocated to Norway and the remaining quota allocated to Russia in both years (Annex 8, Table 2). A ban on all pup catches prevented Russianhunting in the White Sea during the period 20092014. This ban was removed before the 2015 season. However, the availability of ice was too restricted to permit sealing, resulting in no commercial Russian harp seal catches in the

White Sea in 2015 (Annex 7, Table 2). This was also the case in 2016. Also, no Norwegian vessels hunted in the southeastern Barents Sea (the East Ice) in 2015 and 2016. In September 2016, 28 harp seals ( $1+$ animals) were taken for scientific purposes north of Svalbard - presumably from the White Sea/Barents Sea population (Appendix 7, Table 2;).

### 5.3.2 Current research

## Ice conditions and possible influence on harp seal pupping

Information on ice conditions in the White Sea and southeastern part of the adjacent Barents Sea area w as obtained from satellite imagery, ice-charts and ship captains during January-April 2015 and 2016 toexamine possible impacts of ice conditions on harp seal pupping.
In 2015, the remote sensing data showed extensive ice cover, throughout the White Sea and in the adjacent southeastern part of the Barents Sea during February. Ice conditions considered optimum for harp seal pupping were present at this time. During March the ice had largely disappeared from the main 'basin' of the White Sea. Heavier ice remained in the entrance to the White Sea and in southeastern part of the Barents Sea (Fig 4), but warm temperatures and warm southerly winds contributed to ice destruction and by mid-March there was very little ice remaining in the White Sea, with ice cover being restricted along the coast at the entrance tothe White Sea and in the southeasternBarentsSea. A large patch of whelping animals was seen in each of theseareas. Pup mortality was considered to be relatively high.

Figure 4. Map showing ice cover in the White Sea and southeastern Barents Sea on 3 March 2015. Ice map is from the Norwegian Meteorological Institute, TromsØ Norway.

In 2016, suitable ice conditions in the White Sea were observed in January, but the ice deteriorated rapidly and by March suitable ice for harp seal pupping was only observed along the coast at the entrance to the White Sea and in the eastern Barents Sea. Total ice cover was lower than in 2015, but more suitable ice for pupping appeared to be present. Consequently, mortality was considered to be lower in 2016 compared to 2015.

W orking papers on the age of maturity and pregnancy rates of harp seals in the White Sea and estimates of abundance using cohort and stock production models were made available to the working group but were not discussed in detail because the authors were unable to be present (Shafikov SEA244; Korzhev and Zabavnikov SEA242).

### 5.3.3 Biological parameters

For the Barents/White Sea stock an even more pronounced underrepresentation of first time ovulators was observed. Estimates of MAM and MAP were virtually identical for all available samples from the early 1960s to 2006. The implications of this depend on the underlying reason for the small numbers of first time ovulators in the samples. If the main reason was a seasonal delay in timing of first ovulation, MAM will be overestimated, but estimate of MAP w ould be reliable. If the main reason $w$ as spatio-temporal segregation of reproductive classes, MAP may be underestimated due to
underrepresentation of nulliparous females. More information on the seasonal distribution of first time ovulators is needed to understand why they are not being seen in the sample collections.

The WG noted that biological material sufficient for establishing an ogive was last collected in 2006, and that data for calculations of fertility rates have not been collected from this area since 2011. The WG recommends that effor ts be made to obtain samples, to evaluate reproductive rates for use in the population model and body condition information as well.

### 5.3.4 Population assessment

No new survey information.
A new survey is planned for March 2017

## Population Assessment

The population dynamics model has the same structure as that used to model Greenland Sea harp and hooded seals. It incorporates historical catch records, fecundity rates, age specific proportions of mature females, and fits to estimates of pup production to estimate the population trajectory.

Two types of reproductive data are used in the model: information on the proportion of females that are mature at a given age (i.e. maturity ogive) and the proportion of mature females that are pregnant at a given year (i.e. fecundity rate). Estimates of age specific proportions of mature females are available for four historical periods; 19621972, 19761985, 19881993, and 2006 (Table 6; Frie et al., 2003; ICES, 2009; ICES, 2013). For years with no data a linear interpolation of the age specific proportions of mature females between two periods is assumed (Figure 5; ICES, 2013).

Table 6. Estimates of proportions of mature Barents Sea / White Sea harp seal females (p) at ages 215 in four historical periods: $P_{1}=1962-1972 P_{2}=1976-1985 ; P_{3}=1988-1993 ; P_{4}=2006 ;$. Data from ICES (2014).

| AGE | $\mathbf{2}$ | $\mathbf{3}$ | $\mathbf{4}$ | $\mathbf{5}$ | $\mathbf{6}$ | $\mathbf{7}$ | $\mathbf{8}$ | $\mathbf{9}$ | $\mathbf{1 0}$ | $\mathbf{1 1}$ | $\mathbf{1 2}$ | $\mathbf{1 3}$ | $\mathbf{1 4}$ | $\mathbf{1 5}$ |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| P1 | 0 | 0.01 | 0.17 | 0.64 | 0.90 | 0.98 | 0.99 | 1.0 | 1.0 | 1.0 | 1.0 | 1.0 | 1.0 | 1.0 |
| P2 | 0 | 0 | 0 | 0.24 | 0.62 | 0.81 | 0.81 | 0.95 | 0.98 | 0.99 | 0.99 | 1.0 | 1.0 | 1.0 |
| P3 | 0 | 0 | 0.02 | 0.08 | 0.21 | 0.40 | 0.59 | 0.75 | 0.85 | 0.91 | 0.95 | 0.97 | 0.98 | 0.99 |
| P4 | 0.01 | 0.02 | 0.05 | 0.11 | 0.25 | 0.55 | 0.90 | 0.99 | 1.0 | 1.0 | 1.0 | 1.0 | 1.0 | 1.0 |

Figure 5: Proportion of mature females and the interpolated values for years without data among Barents Sea / White Sea harp seals. Values are from Table 6.

The model also uses historical values of the fecundity rates that are obtained through sampling during commercial hunt. BarentsSea / White Sea population fecundity data are available as mean estimates in the period 19901993, and from 2006 and 2011 (Table 7; Kjellqw ist et al., 1995;ICES, 2008; FrieSEA246). The population dynamics model sets fecundity with no variance. For periods where there are no pregnancy rate data, values were interpolated assuming a linear transition from 0.84 in 1990 to 0.68 in 2006, increasing again to 0.84 from 2006 to 2011 . Prior to 1990 a constant pregnancy rate was assumed and set at 0.84 . After 2011, the WG was concerned about the uncertainty in the pregnancy rates and felt that using the last observed fecundity rate in the projections w as not appropriate given observed historical variation. They considered that it was more appropriate to use an average of the observed fecundity rates in the projections.

Table 7. Estimates of proportion of Barents Sea / White Sea harp seal fema les giving birth. Data from ICES (2011) and Frie (SEA246)

| YEAR | FECUNDITY RATE | STANDARD DEVIATION |
| :---: | :---: | :---: |
| 19901993 | 0.84 | 0.05 |
| 2006 | 0.68 | 0.06 |
| 2011 | 0.84 | 0.10 |

Pup production estimates are available from surveys conducted in 19982013 (Table 8) (ICES 2011;2014). The catch records comes from commercial hunt and distinguishbetween the number of pups ( 0 -group) and the numbers of $1+$ animals caught per year, but contain no additional information about the age composition of the catches. The modelling period begins in 1946, because catch data prior to then are unreliable (Iversen, 1927; Rasmussen, 1957; Sergeant, 1991).

Table 8. Timing of Russian surveys, estimated numbers of pups and coefficients of variation (CV) for harp seals in the Barents Sea / White Sea. Numbers and CVs are drawn from ICES (2011) and ICES (2014). All unspecified surveys were flown using multispectral sensing systems

| Year | Survey Period | Estimated Number <br> of Pups | Coefficient of <br> Variation |
| :--- | :--- | :---: | :---: |
| 1998 | $12 \& 16$ March | 286,260 | 0.150 |
| 2000 | 1012 March -photo | $322,474 \mathrm{a}$ | 0.098 |
|  | 18 March - | $339,710 \mathrm{~b}$ | 0.105 |
| 2002 | 20 March | 330,000 | 0.103 |
| 2003 | $18 \& 21$ March | $328,000 \mathrm{c}$ | 0.181 |
| 2004 | 22 March - photo | 231,811 | 0.190 |
|  | 22 March- | 234,000 | 0.205 |
| 2005 | 23 March | 122,658 | 0.162 |
| 2008 | 1920 March | 123,104 | 0.199 |
| 2009 | 1416 March | 157,000 | 0.108 |
| 2010 | 2023 March | 163,022 | 0.198 |
| 2013 | 1521 March | 128,786 | 0.237 |

First 2000 estimates represented the sum of 291,745 pups $(S E=28,708)$ counted plus a catch 30,729 prior to the survey for a total pup production of 322,474
Second 2000 estimate represents the sum of 308,981 pups ( $\mathrm{SE}=32,400$ ) counted plus a catch of 30,729 prior to the survey for a total pup production of 339,710.

2003 estimate represents the sum of 298,000 pups $(S E=53,000$ ) counted, plus a catch of 35,000 prior to the survey for a total pup production of 328,000 .

The estimated population sizes, and priors used are presented in Table 9. Figure 6 shows the model fit to the observed pup productionestimates and the modelled total population trajectory. The fit to the early pup production estimates is poor, and the model does not capture the dynamics of the survey pup production estimates. The model indicates that harp seal abundance in the Barents Sea/White Sea declined from 1946 to the early 1960s, increased from the early 1960s toearly 1980s, but then declined again untilaround 2007. The model suggests an increase in population size since 2007.

The model estimates are stable for various choices in priors. Although the priors for $\mathrm{M}_{0}$, and $\mathrm{M}_{1+}$ are relatively non-informative, increasing the mean of the prior to 0.3 and 0.1 , respectively, caused a $0.1 \%$ change in the total population estimate. Due to the limited data available, mortality cannot be estimated independently and the model estimates of $\mathrm{M}_{0}$ and $\mathrm{M}_{1+}$ are highly correlated (-0.95).

Because the fecundity rates are fixed values in the model, there is no uncertainty associated with this parameter, meaning that the uncertainty of the modelled abundance is underestimated

The 2017 model estimates of abundance is 1197000 ( $95 \%$ CI: 10428001351 200) 1+ animals and 211000 ( $95 \% \mathrm{CI}: 185$ 100236900) pups. Total estimate is 1408000 ( $95 \% \mathrm{Cl}$ : 12516801564 320).

Table 9: Barents Sea / White Sea harp seals: Estimated and derived mean values and standard deviations of the parameters used in the model. Priors used are shown in brackets. $\mathrm{N}_{\max }$ is the historically largest total population estimated by the model, $N_{70}$ is $70 \%$ of $N_{\max }, N_{\text {lim }}$ is $30 \% ~ o f ~ N_{\text {max }}$, and $\mathbf{N}_{\text {min }}$ is the estimated population size using 20 th percentile of the lognormal distribution.

Figure 6: Barents Sea/White Sea harp seals: Modelled population trajectories for pups and adults (full lines), $\mathbf{9 5 \%}$ confidence intervals. Future projections are illustrated by confidence bands. $\mathrm{N}_{70}$, $\mathrm{N}_{50}$, and $\mathrm{N}_{\text {lim }}$ denote the $70 \%, 50 \%$ and $30 \%$ of the historical maximum population size, respectively. Observed pup production estimates and $95 \%$ confidence intervals are shown in blue.

## Catch options

The various catch scenarios requested are:

1) Current catch level (average of the catches in the period 2012 - 2016).

2 ) Equilibrium catch level.
3 ) Catches that would reduce the population to $\mathrm{N}_{70}$ with probability 0.8 over a 15 -years period.

Current catchlevel is defined as the average catch level of the last 5 years, i.e. the average catch level of the period 20122016. For pups there has been zero catch in this period, and for the $1+$ group 9 seals were caught in 2012 and none for the other years. Because of this we have set the current catch level to be zero for both the pups and the $1+$ group. The equilibrium catch level is defined as the (fixed) annual catch level that stabilizes the future $1+$ population under the estimated model over a period of 15 years. It was assumed that no pups were taken in the catch

The last reproductive rates available are based on data from 2006 (ICES, 2011), i.e. more than 5 years old. The WG was concerned about using the last observed fecundity rate of 0.84 in future projections. An average of the most recent observed fecundity rates,
i.e. observed fecundity rates the last 10 years, was used for the population projections. The averaged fecundity rate used for future projections was $\mathrm{F}_{\text {future }}=0.76$.

The harpseal population in the Barents Sea/White Sea is considered data poor because of the time elapsed since the last series of reproductive samples were obtained. As a result the catch option3 (Catches that would reduce the population to N70 with probability 0.8 over a 15 -years period) was not examined.

Since the populations is classified as data poor and is above a critical limit ( N lim) the Potential Biological Removal (PBR) approach for estimating catch quotas should be considered in addition to the requested catch options.
The PBR has been defined as:

$$
P B R=\frac{1}{2} R_{\max } F_{r} N_{\min },
$$

where $R_{\max }$ is the maximum rate of increase for the population, $\mathrm{F}_{\mathrm{r}}$ is the recovery factor with values between 0.1 and 1 , and $\mathrm{N}_{\text {min }}$ is the estimated population size using 20th percentile of the lognormal distribution. $R_{\max }$ is set at a default of 0.12 for pinnipeds.
Given the stillunexplained drop in pup production first observed in 2004 and that the pup production since then seems to remainlow, we used a recovery factor $\mathrm{F} r$ of 0.5 as in the previous assessment. The PBR catch option assumes that the age structure of the removals is proportional to the age composition of the population, i.e. $14 \%$ pups in catch. A catch consisting of a larger proportion of pups would be more conservative, but a multiplier to convert age $1+$ animals to pups is inappropriate for the PBR.

Setting future harvests at the PBR level resulted in a 33\% reduction of the $1+$ population over the next 15 years. Since the model indicates a decline of the population using a PBR catch level with a recovery of $\mathrm{F}_{\mathrm{r}}=0.5$, we also used a smaller recovery rate of $\mathrm{F}_{\mathrm{r}}=$ 0.25 . The model indicated a reduction of $10 \%$ of the $1+$ population over the next 15 yearsusing this PBR catch level. The precision of the 2017 model estimate is fairly high with a CV of 0.07 . The WG feels that the uncertainty of the population dynamics model is underestimated and a CV of 0.07 is too low. Because of this, the resulting PBR catch level is likely to be overestimated. Increasing the CV when calculating the PBR catch level, i.e. increasing the uncertainty about the model estimate of the 2017 abundance, will lower the PBR catch quota. How ever, using $F R=0.5$, and an $N_{\text {min }}$, that assumed a substantial increase of the CV to 0.30 still resulted in a PBR that caused the estimated $1+$ population to decrease by $25 \%$ over the next 15 years. The WG concluded that the PBR catch level was not suitable for providing advice of future catch quotas and recommended that equilibrium catch levels be used.

The estimates for the various catch options are given in Table 10. The model indicates an increase of $12 \%$ for the $1+$ population over 15 years with no catch. Equilibrium catch level is 10090 seals ( $100 \% 1+$ animals). If pups are hunted two pups balance one $1+$ animal.

Table 10. Catch options with relative $1+$ population size ( $\mathrm{D}_{1^{+}}$) in 15-years (2032) for harp seals in the Barents Sea / White Sea.

| CATCH OPTION | PROPORTION <br> PUPS IN <br> CATCHES | PUP <br> CATCH | 1 + <br> CATCH | TOTAL <br> CATCH | CHANGE OF THE 1 + <br> POPULATION OVER 15 YEARS <br> $(95 \% ~ C I) ~$ |
| :--- | :---: | :---: | :---: | :---: | :---: |
| Current level | $0 \%$ | 0 | 0 | 0 | $1.120 .99-1.25$ |
| Equilibrium | $0 \%$ | 0 | 10090 | 10090 | $1.00(0.87-1.13)$ |
| PBR, Fr $=0.50$ | $14 \%$ | 5598 | 34387 | 39985 | $0.67(0.52-0.81)$ |
| PBR, Fr $=0.25$ | $14 \%$ | 2799 | 17193 | 19992 | $0.90(0.76-1.03)$ |
| PBR, $\mathrm{Fr}=0.50, C V=$ <br> 0.3 | $14 \%$ | 4619 | 28371 | 32990 | $0.75(0.61-0.87)$ |

In this assessment, the equilibrium catch, is muchlower than that estimated in the previous assessment. This is because of the lower pregnancy rates assumed in the projections and this highlights the need for new samples.

Furthermore, uncertainty in the reproductive data needs to be incorporated into the assessment model.

### 5.4.1 Information on recent catches and regulatory measures

## Canada

Betw een 2003 and 2010 the harp seal quota in Canada ranges from 270000 to 330000. In 2011 the quota was raised to 400000 . Since then it has been 'rolled over' annually (Annex 8, Table 3). The TAC includes allocations for aboriginal harvesters (currently 6 $840)$, development of new products (20000) and personal use $(2000)$. There is no specific allocation or quotas for catches in Arctic Canada.

Follow ing a peak catch of 365971 harpseals in 2004, catches have declined significantly (Annex 7, Table 4). Despite the high quotas, catches have remained below 80000 since 2009. In 2015, catches dropped to a low of 35304 ( $8.8 \%$ of the TAC) due primarily to the lack of markets. Although still low, catches increased to approximately 66865 ( $16.7 \%$ of the TAC) in 2016. Catches in the Canadian Arctic are not known but are thought to be small (<1000).

The vast majority of harp seals taken in the Canadian commercial hunt are young of the year, accounting for $>98 \%$ of the catch during the past decade. However, in 2016, a small meat hunt for adult seals occurred during late February and early March. The actual age structure of the hunt in 2016 will not be available until Statistics Branch completes their examination of the purchase slips. For this reason the age is listed as unknown. The age structure of the 2015 catches may also change once this check is completed.

## Greenland

Greenland catches of harp sealshave been reported up to 2014. Catches over thepast decade have varied from 59769 in 2012 to 95954 in 2006 with an average catch on 78749 (Annex 7 Table5). The reported catch for 2013 and 2014 w as 81196 and 63059 , respectively. Along the west coast where the majority of seals were caught, the \% adults reported varied between $1 / 4$ and $1 / 3$ of the catch.

The most recent catch reports differ slightly from previous reports. How ever, the reasons for these changes are not clear. Therefore, tables presented here include the previous reported catches for the period up to 2011. They will be updated if necessary once the reason for any changes are clarified (Annex 7, Table 6).

Total reported catches for Canada and Greenland are summarized in Annex 7, Table 3. In Annex 7, Table 7 presents estimated total removals including bycatch in Canadian and US fisheries, and estimates of struck and lost (Stenson and Rosing-Asvid SEA 245). It also assumes that Canadian catches in 2016 were all young of the year.

### 5.4.2 Current research

Female harp seal attendance to their pups, and nursing patterns, under varying environmental conditions were examined at the Front whel ping patch to determine if these patterns change in response to changing weather conditions (Perry et al., 2016). The behaviour of 158 harp seal females and pups was recorded every three minutes during daylight hours; air and water temperature, and windspeed wererecorded at the beginning of each observation session. GAMMmodels were used to examine the importance of time and environmental conditions in predicting attendance and nursing patterns. The best model for predicting attendance included time of day , air temperature, windspeed, and the interactionbetween wind and air temperature. The best model for predicting nursing included $w$ indspeed, air temperature, and time of day. Females were more likely to attend their pups during the afternoon when solar radiation appeared to be high, but reduced attendance during high winds and/or low temperatures. The likelihood of attending females nursing during these poor weather conditions was greater than when conditions were better. Thus, females were less likely to be present when weather conditions were poor but when present, they were more likely to be provisioning their pups. This strategy may help these females defray the thermoregulatory demands on their limited resources while ensuring that their young attain weights that are likely to increase post-weaning survival and hence maternal fitness.

### 5.4.3 Biological Parameters

The long term monitoring of late-term pregnancy rates, fecundity and abortion rates of Northwest Atlantic harp seals has continued with annual samples being collected off the coast of New foundland and Labrador.

Stenson et al. (2016) described a study of late term pregnancy and abortion rates in Northwest Atlantic harp seals based upon samples collected off the coast of Newfoundland, Canada. Since the 1950 s, pregnancy rates have declined while interannual variability has increased. Using a beta regression model to explore the importance of biological and environmental conditions, they found that while the general decline in fecundity is a reflection of density-dependent processes associated with increased population size, including the late term abortion rates captured much of the large interannual variability. Change in the abortion rate is best described by a model that incorporates ice cover in late January and capelin, a major prey of harp seals, biomass obtained from the previous fall. A previous study has shown that capelin abundance is correlated with ice conditions suggesting that late January ice conditions could be considered a proxy for environmental conditions that influence a number of prey species.

Preliminary data on the condition of harpseals collected off the coast of southern Labrador and NE Newfoundland between 1979 and 2012 presented to the WG indicates that there appears to be a positive correlation between annual average condition and
annual pregnancy rates. There appears to be a negative, nonlinear, relationship betw een annual average condition and annual abortion rates. There also appears tobe a strong correlation between mean winter (December - February) blubber thickness and annual pregnancy rates.

### 5.4.4 Population Assessment

No new information on current abundance was presented. However, the importance of the assumption used to describe the density-dependent relationship in the NWA harp seal model was illustrated as part of the advice to Canada (see below).

A new pup production survey is planned for March 2017.

## 6 Hooded seals (Cystophora cristata)

### 6.1 The Greenland Sea Stock

### 6.1.1 Information on recent catches and regulatory measures

Concerns over low pup production estimates resulted in a recommendation from ICES that noharvest of Greenland Sea hooded seals should be permitted, with the exception of catches for scientific purposes (ICES, 2008) (Annex 8, Table 1). This advice w as immediately implemented (Annex 8, Table 1). The total removals of Greenland Sea hooded seals in 1946-2016 are shown in Annex 6, Table 1. Total catches for scientific purposes (all taken by Norway, Russian sealers did not operate in the Greenland Sea) in 2014 were 11 (whereof 5 pups) in 2015 and 18 (whereof 10 pups) in 2016.

### 6.1.2 Current research

## Diet

Hooded seals are important predators in drift ice areas of the Greenland Sea (the West Ice) during spring and summer. Their summer (June-July) diet was studied in the West Ice in 2008 and 2010, based on analysis of gastrointestinal contents of 179 animals obtained in dedicated surveys (Enoksen et al., in press). Polar cod dominated the diet. The importance of the squid Gonatus fabricii w as lower in this study compared with previous hooded seal studies in the area, and krill only occurred sparsely. In addition to the hooded seals, samples of 20 harp seal digestive tracts and 70 harp seal faeces were also obtained during the 2010 survey. The diet composition of the harp seals was dominated by amphipods (primarily Themisto sp.) and deviated significantly from the hooded seal diet, implying that the degree of food competition was relative low. The occurrence of polar cod, Themisto sp. and krill in the diets of the two seal species coincides well with the geographical and vertical distribution of these three prey items and the previously recorded dive depths of the seals. The presence of demersal fish such as sculpins and snailfish in the diet of some hooded seals was more likely a result of increased availability rather than changes in prey preference, as these seals were collected above shallower waters.

## Morphometric data

Morphometric parameters of female hooded seals collected in the Greenland Sea (GS) 19582010 w ere compared to female Northwest Atlantic (NWA) hooded seals from the period 195676. Reproductive data available for a subset of the NWA dataset have previously been shown to exhibit the highest reproductive rates recorded for hooded seals, while reproductive rates for the GS hooded seals have been low during this period of dramatic decline in population size. One of the central findings of the study is that length-at-age of parous females was consistently lower in GS females compared to the NW A hooded seals. Length-at-age of GS hooded seals furthermore declined significantly in the late 1970s and remained low up to the late 1990s. The most recent sample from 2008-10 showed a return to the 1958 level. A similar pattern of decline and subsequent increase occurred for average length of primiparous females (ALPP). ALPP for the period 1958-75 and 2008-10 was not different from value for the NWA samples, but a significant dropin ALPPw as observed during the period 1980-1999. The drop in length-at-age and ALPP in the late 1970s occurred after signs of marked boomand bust dynamics of fisheries for potential hooded seal prey species like redfish and Greenland halibut. Conversely the later increase in length-at-age and ALPP in the 200810 occurred
after a documented recovery of redfish and Greenland halibut in the Norwegian Sea area and aroundSvalbard. These two species have, however, not been documented in diet studies of GS hooded seals, which have focused on the diet in the pack ice areas, dominated by high arctic species like polar cod (Boreogadus saida) and the squid Gonatus fabricii. The geographical distribution of these high Arctic species has likely declined during the warm period after 2000, but the density of prey available to the hooded seals close to the pack ice could have increased.

### 6.1.3 Biological parameters

No new information

### 6.1.4 Populationassessments

No new surveys have been completed
The same population model used for the Greenland Sea harp seal population is used in this assessment of the Greenland Sea hooded seal population.

Maturity curves were constructed based on female reproductive material collected over the period 199094 and 200810 (Table 11, ICES 2011).

Table 11. Estimates of proportions of mature females ( $\mathrm{p}_{\mathrm{i}, \mathrm{t}}$ ). The P1 estimates are from ICES (2008) and the $\mathbf{P} 2$ estimates are from ICES (2011). Mature females had at least one CL or CA in the ovaries.

| AGE | $\mathbf{1}$ | $\mathbf{2}$ | $\mathbf{3}$ | $\mathbf{4}$ | $\mathbf{5}$ | $\mathbf{6}$ | $\mathbf{7}$ | $\mathbf{8}$ | $\mathbf{9}$ | $\mathbf{1 0}$ | $\mathbf{1} \mathbf{1}$ |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| P1 | 0 | 0.05 | 0.27 | 0.54 | 0.75 | 0.87 | 0.93 | 0.97 | 0.98 | 0.99 | 1.00 |
| P2 | 0 | 0 | 0.06 | 0.60 | 0.89 | 0.97 | 0.99 | 1.00 | 1.00 | 1.00 | 1.00 |

The record of historical fecundity rate is sparse, but the observed fecundity rates are all around 0.7 (ICES, 2013). A fixed fecundity rate of $\mathrm{F}=0.7 \mathrm{w}$ as used for allyears when modelling the Greenland Sea hooded seal population.

Pup production estimates are available from aerial surveys conducted in 1997, 2005, 2007, and 2012 (Table 12, ICES, 2011, Salberg et al., 2008, Øigård et al., 2014). Catch levels for the period 1946 - 2016 are presented in Annex 6, Table 1.

Table 12. Estimates of Greenland Sea hooded seal pup production, based on data from ICES (2011), Salberg et al., 2008 and Øigård et al., 2014.

| Year | Estimated Number of Pups | Coefficient of Variation. |
| :---: | :---: | :---: |
| 1997 | 23762 | 0.192 |
| 2005 | 15250 | 0.228 |
| 2007 | 16140 | 0.133 |
| 2012 | 13655 | 0.138 |

The estimated population, along with the parameters for the normal priors used are presented in Table 13. The mean of the prior for M0 was set to be three times the mean of M1+.

The population trajectory is shown in Figure 7. The model indicates a substantial decrease in abundance from the late 1940s and up to the early 1980s. In the most recent two decades, the population appears to have stabilized at a low level.

A 2017 abundance of 66860 1+ animals ( $95 \%$ CI: 4586087 860) and $13600(95 \%$ CI: 9 25017950 ) pups is obtained. The estimated total2017 population of hooded seals in the Greenland Sea is 80460 ( $95 \%$ CI: 59020101 900). For comparison the total estimated population of hooded seals on the Greenland Sea w as 82830 seals in 2013 and 85790 in 2011 (ICES, 2011; 2013).

Table 13: Greenland Sea hooded seals: Estimated mean values and standard deviations of the parameters used in the model. Priors used are shown in brackets. $\mathbf{N}_{\max }$ is the historically largest total population, N 70 is $70 \%$ of $\mathrm{N}_{\text {max }}, \mathrm{N}_{\text {lim }}$ is $30 \%$ of $\mathrm{N}_{\text {max }}$, and $\mathrm{N}_{\text {min }}$ is the estimated population size using 20th percentile of the lognormal distribution.

|  |  |  |
| :--- | :---: | :---: |
|  | PARAMETERS | MEAN |
| N0y | 1086890 | SD |
| M0 | 0.34 | 394940 |
| M1+ | 0.17 | 0.02 |
| $N_{\text {max }}$ | 1302800 | 0.05 |
| $N_{70}$ | 911960 | - |
| $N_{\text {lim }}$ | 390840 | - |
| $N_{\text {min }}$ | 75241 | - |
| $N_{0,2017}$ | 13600 | - |
| $N_{1+, 2017}$ | 66860 | 2218 |
| $N_{\text {Total,2017 }}$ | 80460 | 10714 |

## Catch options

All model runs indicate a population currently well below Nlim (30\% of largest observed population size). Following the precautionary approach framework developed by WGHARP (ICES2005), no catches should be taken from this population.

Figure 7: Greenland Sea hooded seals: Modelled population trajectories for adults (a) and pups (b) (mean=solid line, $95 \%$ confidence intervals= shaded area). Projections are illustrated by confidence bands. $\mathrm{N}_{70}, \mathrm{~N}_{50}$, and $\mathrm{N}_{\text {lim }}$ denote the $\mathbf{7 0 \%}, 50 \%$ and $30 \%$ of the historical maximum population size, respectively. Observed pup production estimates and $95 \%$ confidence intervals are shown in blue.

### 6.2 The Northwest Atlantic Stock

### 6.2.1 Information on recent catches and regulatory measures

Under the Canadian AtlanticSeal ManagementStrategy (Hammill andStenson 2007), Northwest Atlantichooded seals are considered to be data poor. Under this approach, TACs are set using PBR. Prior to 2007, the TAC for hooded seals was set at 10000 (Annex 8, Table 4). As a result of new data on the status of the population (Hammill and Stenson 2006) the quota was reduced to 8200 in 2007 where it has remained. The killing of young of the year hooded seals (bluebacks) is prohibited in Canada.

Canadian catches of hooded seals (1+ only) have remained extremely low in recent years (Annex 6, Table 2). Catches have remained less than 50 since 2005 with most years being less than 10 . Reported catches in 2015 and 2016 were 1 and 13 respectively.

Greenland catches of hooded seals since 2009 have been between 100 and 2 100, which is much lower than catches prior to 2005 which were generally between 50007000 animals (Annex 6, Table3). A total of 1520 hooded seals were reported taken in 2013 while 1846 were reported caught in 2014. With the exception of 1 seal taken in 2014, all of these animals were considered to be from the Northwest Atlantic hooded seal population.

### 6.2.2 Current Research

The WG noted that the collection of small numbers of hooded seals has continued in Canada. When analysed, these samples may provide some new data on diets, condition and reproductive rates. However, sample sizes are small.

### 6.2.3 Population Assessments

No new information. Canada is exploring the possibility of obtaining a minimum pup production from photos obtained during the 2012 harp seal survey.

### 7.1 Request for advice submitted to ICES by Norway

In October, 2015, Norway requested management advice on the status of harp and hooded seal stocks in the Greenland Sea and the harp seal stock in the White Sea/Barents Sea.

ICES w as asked to assess the impact on the harp seal stocks in the Greenland Sea and in the White Sea/Barents Sea of an annual harvest of:

1 ) current harvest levels,
2 ) sustainable catches (defined as the fixed annual catches that stabilizes the future $1+$ population)
3 ) catches that would reduce the population over a 15-years period in such a manner that it w ould remain above a level of $70 \%$ of the maximum population size, determined from population modelling, with $80 \%$ probability.

The advice on status and impacts of different harvest options are provided in previous sections of this report. Section 4.2.5 provides advice on Greenland sea harps, section 4.3.4 on White sea harps and section 5.1.4 on Greenland sea hooded seals.

### 7.2 Request for advice submitted to NAFO by Canada

In 2014 Canada requested that WGHARPexplore the impact of proposed harvest strategies that w ould maintain the Northwest Atlantic harp seal population at a precautionary level of a PA framework and that would have a low risk of decreasing below the critical level. Specifically, the WG was asked to:

1 ) Identify the catches necessary to reduce the NWA harp seal population to 5.4 M animals assuming:
a ) Catches consisting of $90 \%$ Young of the Year (YOY) or $50 \%$ YOY
b ) Reductions over periods of 5,10, and 15 years
2 ) Identify the catches necessary to reduce the population to 6.8 M assuming:
a ) Catches consisting of $90 \%$ YOY or $50 \%$ YOY
b ) Reduction over periods of 5, 10, and 15 years
3 ) Identify sustainable future catches possible at each of these reduced populations, assuming there is a $95 \%$ probability of remaining above the Limit Reference Point (defined as 2.4 million).

This request was considered at the 2014 meeting but it was not completed at that time. It was agreed that the advice would be provided at the 2016 meeting.

To examine the impacts of the different population reduction scenarios, Hammill et al. (SEA243) projected the 2014 NWA harp seal population model into the future, using as a starting point, the estimates of 2014 population size, pup production, natural mortality (M), and carrying capacity (K).

Assumptions associated with future reproductive rates and levels of the Greenland catch are necessary. Therefore, the impacts of the different Canadian catch options on the projected population under two major scenarios that represent a continuation of the current state (Model A) and an alternate model that responds to the impact of removals by assuming density-dependent compensation, i.e. decreased catches and increased reproductive rates when populations are reduced (Model B). In Model A, it
was assumed that future reproductive rates, and Greenland catches were based upon the observed rates from the past 10 years (Table 14). In Model B, both future reproductive rates and Greenland catches behaved in a density-dependent manner, i.e. as the population declines, Greenland catches decline and pregnancy rates increase to an asy mptotic value, whereas when the population increases, Greenland catches increase to an asymptotic value and reproductive rates decline.

In both scenarios, $i$ is assumed that the age structure and mortality from bycatch and the Canadian Arctic harvest remain constant at 2013 levels and that the proportion of seals struck and loss, for the different harvests remain unchanged.

Table 14. Comparison of model assumptions

|  | MODEL A | MODEL B |
| :--- | :--- | :--- |
| Greenland catches | Fixed at average over past 10 <br> years | Catches vary with population <br> size when less than7.1 million <br> harp seals |
| Ice related mortality | Selected randomly froma <br> vector of recently observed <br> rates | Same |
| Pregnancy rates | Selected from vector of <br> recently observed rates | Density-dependent- decreases <br> as population approaches <br> carry capacity |
|  |  | Proportion pregnant varied to <br> account for changes in food <br> supply (based upon recent <br> observations) |
|  | Density-dependent- increases <br> as population approaches <br> carry capacity | Same |
| Mortality rates ofYOY |  |  |

Once the target population level was achieved, the model was further projected forward to determine the level of catches that will respect the management plan (i.e. 95\% likelihood of population remaining above the Limit Reference Level) for an additional 15 years whichensures that catches are sustainable while they propagate through the population age structure. Therefore, the total length of the projection varied with each reduction scenario (i.e. total of 20,25 and 30 years). However, since the management objective changed following the reduction, the mean estimated population did not necessarily remain at the target level.

The predicted changes in the population trajectory were affected very strongly by the age composition of the harvest used to reduce the population, the speed with which the reduction was achieved and whether the scenario used a population whose dynamics were assumed to be similar to what has been seen in the past 10 years (Model A) or assumed to vary in a density-dependent manner (Model B).

## Model A Scenario

A large number of animals w ould need to be removed if the population reduction was to be achieved rapidly, or with a harvest comprised primarily of YOY (Table 15). For a population whose future dynamics are described by current conditions (Model A), up to 610,000 animals would need to be removed if the population was to be reduced to 6.8 million w ithin 5 years. Fewer animals need to be removed annually if the removals were spread over a longer time period, or if animals aged $1+$ years comprised a larger proportion of the harvest (Table 15). It was not possible to achieve a target population of 5.4 million seals within 5 years (Table 15) if YOY comprised $90 \%$ or more of the harvest

Once the target level was achieved, the catch levels that would ensure a $95 \%$ probability of remaining above the Limit Reference Level were much lower than the harvest levels allow able during the reduction phase (Table 15).

Large removals were needed to reduce the population within 5 years, particularly if a large proportion of YOY were taken in the harvest. These removalshad a longer term impact on the population than those that were spread over a longer time period, or had a larger proportion of older seals. In the 5 year scenario to reduce the population to 6.8 million animals, the population continued to decline during the subsequent monitoring period, although there was still a $95 \%$ probability of the population remaining above the Limit Reference Level.

## Model B

The estimated number of removalsneeded toreduce the population to 6.8 million was similar under the two modelling scenarios. Higher harvests were estimated over the following 15 years, while still ensuring that the population had a $95 \%$ probability of remaining above the reference limit point, under the assumptions of Model B, (i.e. den-sity-dependent responses). This is because of the compensation assumed in reproductive rates and catches.

The catch levels needed to reduce the population to 5.4 million were much higher under the assumptions of Model B (i.e. density-dependence), compared to the assumptions used in Model A (Table 16). How ever, as in Model A, harvests had to be reduced considerably once the target was reached to allow the population to remain above the Limit Reference Level (Table 16).

Once the target population level was reached, the continuing catches that had a 95\% likelihood that the population remained above the Limit Reference Level were estimated. The management objective did not require the population to remain at the target level and in some scenarios the population continued to decline. As a result, catches may have to be reduced fur ther following the 15 year simulation period as the population was predicted to decline during the post reduction period.

Table 15. Annual removals ( 000 's) needed to reduce the population from current levels to 6.8 or 5.4 million within a period of 5,10 or 15 years. Catches were assumed to comprise $\mathbf{9 0} \%$, or $50 \%$ young of the year (YOY). Continuing annual removals ( 000 's) represent the total removals allowed that would maintain a $95 \%$ likelihood that the population would remain above the Limit Reference Level ( $\mathrm{N}_{30}$ ) for 15 years. Simulations examined removal impacts assuming future reproductive rates and Greenland harvests were similar to those seen over the past decade (Model A).

| SCENARIO | $90 \%$ YOY |  | $50 \%$ YOY |  |
| :---: | :---: | :---: | :---: | :---: |
|  | REDUCTION | CONTINUING | REDUCTION | CONTINUING |
| 6.8 M |  |  |  |  |
| 5 Y | 610 | 350 | 270 | 190 |
| 10 Y | 450 | 250 | 220 | 150 |
| 15 Y | 400 | 230 | 190 | 100 |
| 5.4 M |  |  |  |  |
| 5 Y |  |  | 480 | 90 |
| 10 Y | 670 | 100 | 320 | 40 |
| 15 Y | 540 | 40 | 260 | 20 |

* indicates target impossible to achieve in time frame and age composition

Table 16. Annual removals ( 000 's) needed to reduce the population from current levels to 6.8 or 5.4 million within a period of 5,10 or 15 years, assuming future reproductive rates and Greenland harvest follow a density-dependent manner (Model B). Catches were assumed to comprise $90 \%$, or $50 \%$ young of the year (YOY). Annual continuing removals ( 000 's) represent the total removals allowed that would maintain a $95 \%$ likelihood that the population would remain above the Limit Reference Level ( $\mathrm{N}_{30}$ ) for 15 years.

| FIXED | $90 \%$ YOY |  | 50\%YOY |  |
| :---: | :---: | :---: | :---: | :---: |
|  | REDUCTION | CONTINUING | REDUCTION | CONTINUING |
| 6.8 M |  |  |  |  |
| 5 Y | 560 | 560 | 250 | 280 |
| 10 Y | 420 | 500 | 200 | 260 |
| 15 Y | 370 | 500 | 180 | 270 |
| 5.4 M |  |  |  |  |
| 5 Y | $*$ | 400 | 560 | 250 |
| 10 Y | 860 | 300 | 350 | 200 |
| 15 Y | 70 |  |  | 170 |

* indicates target impossible to achieve in time frame and age composition

Under all scenarios, the uncertainty associated with estimates of population size increased considerably as time since the last survey also increased.

The management objective for this exercise was to have a $95 \%$ likelihood of remaining above the Limit Reference Level ( 2.4 million) rather than to maintain the population at the reduction target level. As a result, in some scenarios, high catches could be taken after the initial reduction. How ever, these would result in a continued decline in the population. If the management objective had been to maintain the population at the reduction target level, the ' post reduction' catches would have been much smaller. For
example, in the scenario where the population is reduced to 6.8 million over 5 years and the assumptions used for Model B, the catches that would maintain the population would be $\sim 390,000$ (vs 560,000)

These simulation results are very sensitive to model assumptions and should be considered for illustration only. For example, we assumed that the density-dependent relationship could be described using a theta=2.4. Using the same level of harvest but assuming a density-dependent relationship using a theta=1 results in a much lower catch to maintain the population at the same level (Fig 8).

Fig 8. Comparison of catch levels that would result in a constant population after the reduction has occurred, under the assumption that the density-dependent relationship can be described using Theta $=1$ (top) or Theta $=2.4$ (bottom). Scenario assumes that the population is reduced to 6.8 million within 5 years.

The impact of these scenarios on the Greenland hunt will depend upon the assumptions used. Under Model A, it is assumed that the hunt remains the same as it currently is, even if the total abundance is reduced. Under Model B, the availability of animals is the main force driving harvest levels in Greenland and catches decline as the population is reduced. Under this scenario, there w ould appear to be little impact on number of animals available to Greenland hunters if the herd was reduced to 6.8 million. However, a reduction in the herd to 5.4 million animals could result in a $25 \%$ reduction in availability of animals to Greenland hunters. Clearly, the age composition of the catch ( $90 \%$ or $50 \%$ YOY) and rate of the reduction would have an impact on the number of YOY available to Greenland hunters during the reduction period. How ever, while the proportion of YOY in the population was slightly higher if density-dependence was assumed, both scenarios resulted in estimates of YOY that w ere similar to that seen in the past, once the initial reduction is completed.

The WG emphasizes that these simulation results are very sensitive to model assumptions and should be considered for illustration only. It also notes that these scenarios do not include the potential impacts of an unusual mortality event.

Fur thermore, the estimated carrying capacity is based upon historical conditions that may no longer apply. This willimpact our assumptions about density-dependent compensation in reproductive rates (particularly for the 6.8 million scenario).

The two models represent two unlikely situations, one assumes reproductive rates and catches do not respond to changes in total population while the other assumes full compensation in reproductive rates and catches as the population declines. Based upon historical changes in reproductive rates, we expect that some density-dependent compensation will occur, but recent environmental changes suggest that full compensation may not result.

## Other business

If necessary, the WG will work by correspondence during 2017. The next meeting is proposed for September 2018 in Greenland or Norway

## 8 Adoption of the report

The WG adopted the report on 21 November 2014, at the close of the meeting.

## Annex 1: List of participants

## Annex 2: Agenda

Monday, 26 September 2016
$10: 00 \mathrm{pm}$ to noon

- Introductory Comments
- Discussion of Terms of References
- Varia

Noon to 1:30 pm lunch
1:30pm to 5:00pm - Harp Seals: Harp Seals: Greenland Sea Stock

- Biological parameters
- Population model new developments
- Current harvests
- Catch options

5:00pm Break for Day
Tuesday, 27 September 2016
9:00 am to noon - Harp Seals: Harp Seals: Greenland Sea Stock

- Continue Monday discussions on population model

Noon to 1:00pm - Lunch
1:00pm to 5:00pm - White Sea and Barents Sea Stock

- Biological parameters
- New estimates
- Population assessment ()

5:00pm Break for Day
Wednesday, 28 September 2016
9:00am to noon -- Harp Seals: Northwest Atlantic Stock

- Biological parameters
- Population assessment
- Population Model development
- Population modelling development and simulation scenarios
- Impacts on Greenland harvest

Noon to 1:00pm - lunch
1:00pm to $3: 00 \mathrm{pm}$--

- Discussion of way forward?

3:30pm to $4: 30 \mathrm{pm}$-Hooded seals NE Atlantic

- Biology,
- Catches
- New research

4:30pm Break for Day

Thursday, 29 September 2016
9:00am to 10:00am-Hooded seals NW Atlantic

- biology
- Catches
- New research

10:00 to noon

- Write report

Noon to 1:00pm - Lunch
1:00pm to $3: 00 \mathrm{pm}-$

- Write report

3:30pm - 4:30

- Review report

4:30 Break for Day

Friday, 30 September 2016
9:00 am to noon

- Review/complete report
- Next meeting
- Other business

12:00 end meeting

## Annex 3: WGHARP terms of reference for the next meeting

The Working Group on Harp and Hooded Seals (WGHARP) (Chair: Mike Hammill) proposed to meet in Greenland or Norway in late September 2018 to:

- Review results of new surveys as available for harp seals in the White Sea and southeastern portion of Barents Sea
- Review results from the biological samples obtained from the harp seals
- Provide advice on other issues as requested

WGHARP will report September 2018 for the attention of the ACOM.

## Annex 4: Recommendations

| Recommendation | Action by | Recipient |
| :---: | :---: | :---: |
| The WG recommends thatefforts be made to obtain samples, to evaluate reproductive rates for White Sea harp seals, partic ularly in years when an aerial survey is completed. These are required for use in the population model. | 2017 | Norway/Russia |
| The WG recommends thatefforts be made to incorporate bycatch and age composition information from the 'seal inv asion years' in the mid to late 1980 sbe incorporated into the White Sea harp seal model as additional catch data. | 2018 | Norway/Russia |
| The WG recommends that new aerial surveys be conducted to estimate pup production of harp seals in the White Sea $\backslash$ Barents Sea and NW Atlantic in 2017 and Greenland Sea in 2018 | March 2017/2018 | Russia/Norway/Canada |
| The WG recommends that during all aerial surveys, staging surveys also be conducted to determine the correction for pups not av ailable to be photographed when the aerial survey is flown. This should be done for all populations of harp and hooded seals. | Continuing | Canada/Norway/Russia |
| The WG recommends that satellite telemetry tagging studies be undertaken of the White Sea $\backslash$ Barents Sea harp seal population | 2017 | Norway/Russia |
| The WG recommends that uncertainties in reproductive rates be incorporated into the Greenland and White Seaharp seal population models | 2018 | Norway |
| The WG recommended that if possible the Greenland Sea and White Sea harp seal markrecapture data be re-examined and updated with new information if available. | 2018 | Norway |
| The WG recommended that the Greenland Sea assessment takes into account catches from east Greenland | 2018 | Norway |
| The WG recommends that all new data on hooded seals be examined to increase understanding of currentstatus of these populations | 2018 | Canada/Norway |

a For the period 1946-1970 only 5-year averages are given.
b For 1955, 1956 and 1957 Soviet catches of harp and hooded seals reported at 3,900, 11,600 and 12,900, respectively. These catches are not included.
c Including 1048 pups and 435 adults caught by one ship which was lost.

Table 2. Canadian catches of hooded seals off Newfoundland and in the Gulf of St Lawrence, Canada ("Gulf" and "Front"), 19462016a,b. Catches from 1995 onward includes catches under personal use licences. YOY refers to Young of Year. Catches from 19901996 were not assigned to age classes. With the exception of 1996 , all were assumed to be $1+$.

a For the period 1946-1970 only 5-years averages are given.
b All values prior to 1990 are from NAFO except where noted; recent years are from Stenson (2009) and DFO Statistics Branch.
c Landsmen values include catches by small vessels (< 150 gr tons) and aircraft.
d Large vessel catches represent research catches in Newfoundland and may differ from NAFO values.
e Statistics no longer split by age; commercial catches of bluebacks are not allowed
f Number of YOY based upon seizures of illegal catches

a For the period 1946-1970 only 5-year averages are given.
b For 1955, 1956 and 1957 Soviet catches of harp and hooded seals reported at 3,900, 11,600 and 12,900, respectively (Sov. Rep. 1975). These catches are not included.
c Including 1431 pups and one adult caught by a ship which was lost.

${ }^{\text {a }}$ For the period 1946-1970 only 5-year averages are given.
${ }^{\text {b }}$ Incidental catches of harp seals in fishing gear on Norwegian and Murmansk coasts are not included (see Table 6).
c Approx. 1300 harp seals (unspecified age) caught by one ship lost are not included.
${ }^{\text {d }}$ An additional 250-300 animals were shot but lost as they drifted into Soviet territorial waters.
${ }^{\text {e }}$ Russian catches of $1+$ animals after 1987 selected by scientific sampling protocols.
${ }^{\mathrm{f}}$ Included 717 seals caught to the south of Spitsbergen, east of 140 E, by one ship which mainly operated in the Greenland Sea.

Table 3. Reported catches of harp seals in the Northwest Atlantic for 19522016. Estimated catches are indicated by shading. The Greenland catches are made up of the Table 5 West Greenland catches and $1 / 2$ of the SE Greenland. The other half of the SE Gre enland and the NE Greenland are assigned to the West Ice population (Stenson and Rosing-Asvid SEA245).

a For the period 1946-1975 only 5-years averages are given.
b All values prior to 1990 are from NAFO except where noted, recent data from Stenson (2009) and DFO Statistics Branch.
c Landsmen values include catches by small vessels (< $\mathbf{1 5 0} \mathbf{~ g r}$ tons) and aircraft.
d NAFO values revised to include complete Quebec catch (Bowen, W.D. 1982)
e Large vessel catches represent research catches in Newfoundland and may differ from NAFO values

Table 5. Catches of harp seals in Greenland, 1954-1987 (List-of-Game), and 1993-2014 (Piniarneq), and \% adults according to the hunters' reports (Stenson and Rosing-Asvid SEA245).

${ }^{1}$ Other regulations include: Prescriptions for date for departure Norwegian port; only one trip per season; licensing; killing methods; and inspection.
${ }^{2}$ Basis for allocation of USSR quota.
${ }^{3}$ Breeding females protected; two pups deducted from quota for each female taken for safety reasons.
${ }^{4}$ Adult males only.
${ }^{5} 1$ year+ seals protected until 9 April; pup quota may be filled by 1 year+ after 10 April.
${ }^{6}$ Any age or sex group.
${ }^{7}$ Included 750 weaned pups under permit for scientific purposes.
${ }^{8}$ Pups allowed to be taken from 26 March to 5 May.
${ }^{9}$ Half the quota could be taken as weaned pups, where two pups equalled one 1+ animal.
${ }^{10}$ The whole quota could be taken as weaned pups, where two pups equalled one $1+$ animal.
${ }^{11}$ Russian allocation reverted to Norway.
${ }^{12}$ Quota given in 1+ animals, parts of or the whole quota could be taken as weaned pups, where 1,5 pups equalled one 1+ animal.
${ }^{13}$ Quota given in 1+ animals, parts of or the whole quota could be taken as weaned pups, where 2 pups equalled one 1+ animal.
${ }^{14}$ Hooded seals protected, only small takes for scientific purposes allowed.

[^0]Table 3. Major management measures implemented for harp seals in Canadian waters, 1961-2016.

| YEAR | MANAGEMENT MEASURE |
| :---: | :---: |
| 1961 | Opening and closing dates set for the Gulf of the StLawrence and Front areas. |
| 1964 | First licensing of sealing vessels and airc raft. Quota of 50,000 set for southern Gulf (effective 1965). |
| 1965 | Prohibition on killing adult seals in breeding or nursery areas. Introduction of licensing of sealers. Introduction of regulations defining killing methods. |
| 1966 | Amendments to licensing. Gulf quota are as extended. Rigid definition of killing methods. |
| 1971 | TAC for large vessels set at 200,000 and an allowance of 45,000 for landsmen. |
| 1972-1975 | TAC reduced to 150,000, including 120,000 for large vessel and 30,000 (unregulated) for landsmen. Large vessel hunt in the Gulf prohibited. |
| 1976 | TAC was reduced to 127,000. |
| 1977 | TAC increased to 170,000 for Canadian waters, including an allowance of 10,000 for northern native peoples and a quota of 63,000 for landsmen (includes various suballocations throughout the Gulf of StLawrence and northeastern Newfoundland). Adults limited to 5\% of total large vessel catch. |
| 1978-1979 | TAC held at 170,000 for Canadian waters. An additional allowance of 10,000 for the northern native peoples (mainly Greenland). |
| 1980 | TAC remained at 170,000 for Canadian waters including an allowance of 1,800 for the Canadian Arctic. Greenland was allocated additional 10,000. |
| 1981 | TAC remained at 170,000 for Canadian waters including 1,800 for the Canadian Arctic. An additional allowance of 13,000 for Greenland. |
| 1982-1987 | TAC increased to 186,000 for Canadian waters including increased allo wance to northern native people of 11,000. Greenland catch anticipated at 13,000. |
| 1987 | Change in Seal Management Policy to prohibit the commercial hunting of white coats and hunting from large ( $>65 \mathrm{ft}$ ) vessels (effective 1988). Changes implemented by a condition of licence. |
| 1992 | First Seal Management Plan implemented. |
| 1993 | Seal Protection Regulations updated and incorporated in the Marine Mammal Regulations. The commercial sale of whitecoats prohibited under the Regulations. Netting of seals south of $54^{\circ} \mathrm{N}$ prohibited. Other changes to define killing methods, control interference with the hunt and remove old restrictions. |
| 1995 | Personal sealing licences allowed. TAC remained at 186,000 including personal catches. Quota divided among Gulf, Front and unallocated reserve. |
| 1996 | TAC increased to 250,000 including allo cations of 2,000 for personal use and 2,000 for Canadian Arctic. |
| 1997 | TAC increased to 275,000 for Canadian waters. |
| 2000 | Taking of whitecoats prohibited by condition of license |
| 2003 | Implementation of3 y ear management plan allowing a to tal harvestof 975,000 over 3 years with a maximum of 350,000 in any one year. |
| 2005 | TAC reduced to 319,517 in final year of3 year management plan |
| 2006 | TAC increased to 335,000 including a 325,000 commercial quota, 6,000 original initiative, and 2,000 allocation each for Personal Use and Arctic catches |
| 2007 | TAC reduced to 270,000 including 263,140 for commercial, 4,860 for Aboriginal, and 2,000 for Personal Use catches |
| 2008 | TAC increased to 275,000 including a 268,050 for commercial, 4,950 for Aboriginal and 2,000 for Personal Use catches Implementation of requirement to bleed before skinning as a condition of licence |

| YEAR | MANAGEMENT MEASURE |
| :--- | :--- |
| 2009 | TAC increased to 280,000 based upon allocations given in 2008 plus an <br> additional 5,000 for market development <br> Additional requirements related to humane killing methods were implemented |
| 2010 | TAC increased to 330,000 |
| 2011 | TAC increased to 400,000 |

Table 4. Major management measures implemented for hooded seals in Canadian waters for 19642016.

| YEAR | MANAGEMENT MEASURE |
| :---: | :---: |
| 1964 | Hunting of hooded seals banned in the Gulf area (below 50oN), effective 1965. |
| 1966 | ICNAF assumed responsibility for management advice for Northwest Atlantic. |
| 1968 | Open season defined (12 March-15 April). |
| 1974-1975 | TAC setat 15,000 for Canadian waters. Opening and closing dates set (20 March24 April). |
| 1976 | TAC held at 15,000 for Canadian waters. Opening delayed to 22 March. Shooting banned between 23:00 and 10:00 GMT from opening until 31 March and between 24:00 and 09:00 GMT thereafter (to limit loss of wo unded animals). |
| 1977 | TAC maintained at 15,000 for Canadian waters. Shooting of animals in water prohibited (to reduce loss due to sinking). Number of adult females limited to $10 \%$ of total catch. |
| 1978 | TAC remained at 15,000 for Canadian waters. Number of adult females limited to $7.5 \%$ of total catch. |
| 1979-1982 | TAC maintained at 15,000. Catch of adult females reduced to 5\% of to tal catch. |
| 1983 | TAC reduced to 12,000 for Canadian waters. Previous conserv ation measures retained. |
| 1984-1990 | TAC reduced to 2,340 for Canadian waters. |
| 1987 | Change in Seal Management Policy to prohibit the commercial hunting of bluebacks and hunting from large (>65ft) vessels (effective 1988). Changes implemented by a condition of licence. |
| 1991-1992 | TAC raised to 15,000. |
| 1992 | First Seal Management Plan implemented. |
| 1993 | TAC reduced to 8,000. Seal Protection Regulations updated and incorporated in the Marine Mammal Regulations. The commercial sale ofbluebacks prohibited under the Regulations. |
| 1995 | Personal sealing licences allowed (adult pelage only). |
| 1998 | TAC increased to 10,000 |
| 2000 | Taking of bluebacks prohibited by condition of license. |
| 2007 | TAC reduced to 8,200 under Objective Based Fisheries Management based on 2006 assessment |
| 2008 | Implementation of requirement to bleed before skinning as a condition of license |
| 2009 | Additional requirements implemented to ensure humane killing methods are used |

## Annex 9: Technical minutes from the Review Group for the ICES WGHARP REPORT 2016 (Norwegian request)

27 Oct 2016 revised 30 Oct 2016
Participants: Karin Harding (Chair), Mario Acquarone and Sinéad Murphy;
W orking Group: WGHARP 2016
Chair WG:
Secretariat:

## The Review Group considered the following stocks:

- Harp seal Greenland Sea
- Harp seal White Sea/Barents Sea
- Hooded Seal Greenland Sea

## And the following special requests:

- Assess the status and harvest potential of the three stocks

Especially assess the impact of
1 ) current harvest levels,
2 ) sustainable catches (defined as the fixed annual catches that stabilizes the future $1+$ population)
3 ) catches that would reduce the population over a 15-years period in such a manner that it w ould remain above a level of $70 \%$ of the maximum population size, determined from population modelling, with $80 \%$ probability.

## General

The Review Group (RG) acknowledges the immense effort expended by the Working Group (WG) to produce the report. The report is well written and well thought through and the best data and literature available on the species of concern have been used. However, the RG has some comments on the methodology and suggestions for complementary methods and literature that we hope can be valuable in future developments of the model framework and, consequently, in the population assessments.

## Introduction

The report describes the biological status of pinniped stocks in the high Arctic. These populations inhabit one of the most difficult habitats to survey in the w orld, the polar drift ice. Despite incomplete datasets, the authors have used every piece of information available to them to put together a picture of seal abundance, growth rate and the potential for harvest. We acknow ledge the difficulty of this task.

## The RG would like to stress the following points

There are no reliable estimates of population abundance from surveys for these populations, but there are indications of abundance given as data on pup production and harvest data. There are also biological data on pinniped life history. These pieces of information are tied together in a population dynamics model and this is how abundance is estimated. Therefore, every model assumption is vital.

## Our main points are the following

- The basic population dynamic model is sound but can be further improved by applying the precautionary principle in each step in selecting parameter values. As it now stands the basic intrinsic rate of increase ( $r$ ) is not given explicitly for different parameter values. There is a risk that the model is over optimistic in its estimates of sustainable catches.
- How is uncertainty in population abundance included in estimates of sustainable catches?

## For single-stock summary sheet advice:

Stock 4.2 The Greenland Harp Seal stock
Short description of the assessment: extremely useful for reference of ACOM!
1 ) Assessment type:
2 ) Assessment: abundance, potential for catches
3 ) Forecast:presented (for future population size given different hunting regimes)

4 ) Assessment model: Population projection model fitted to some empirical data on reproduction and pup production. 2. Bayesian model trying to fit the population model to data on pup production, initial population sizes.
5 ) Consistency:
6 ) Stock status: Seem to be at safe levels 650300 ( $95 \%$ CI: 471200 - 829300 ) according to the model
7 ) Man. Plan.: Current harvest is at historically low levels and seem to be at the safe side 1442 in 2016 . How ever, in 2013 as many as 16033 animals were hunted (whereof 2245 were older than pups). Suggested quotas of about 20000 seals might cause rapid decline depending on population parameters.

## General comments

This is an ambitious and very professional section. However, the RG still has some points of concern.

## Technical comments

## A. The Population model and parameter values chosen

The main construction of the population model is good and straightforward. But there are a number of question marks in the parameterization. The most important aspect of a population model is which inherent rate of population increase it assumes/obtains through model parameterizations. This growth rate (often termed $r$ in the literature) will govern everything in model predictions and affect which catches the population is thought to sustain. The modelsintrinsicr (for different settings of parameter values) is not clearly stated in the report.

High grow th rate ( $r$ ) allows for higher catches. High growth rates result from: (1). Early female sexual maturity (2). High pregnancy rates (3). Low mortality rates. In order to apply a pre-cautionary principle, it is therefore important not to over/ misestimate these parameters, i.e. propose a high growth rate in data poor populations, but to try to stay on the safe side.

1 ) Age at sexual maturity is well documented by the WG and is nicely included year by year in the estimation of historical population size. However, for the projection this number is kept constant. Suggestion: For future projections it would be best to allow age at maturity to vary within the same range as the historical data has varied and randomize if it is a "good year" or a "bad year" (See Caswell 2011), as it is now it seems an average value is used for all future years.

2 )
2.1 ) Fertility rate in this case pregnancy rate) was estimated by examining females that were caught within a few weeks or months of the breeding season for the presence or absence of a large partially luteinized Corpus albicans. This may overestimate pup production as females that just ovulated and did not become pregnant, and females that had pregnancies ending in abortions may leave signs that look like successful breeding. A lower value should be assumed.
2.2) An average pregnancy rate is used for future projected population size. Suggestion: For future projections randomize good-years and bad-years pregnancy rates from the historical distribution.
3 )
3.1) Mortality rates are unknown. But assumed to be 0.3 for pups and 0.1 for adults. These parameters are crucial to the resulting $r$. A literature review of survival rates of phocid seals indicate that pup mortality can beeven higher than 30\% especially in bad years it can be close to 100\% (Härkönen et al., 2002, Kjellqvist et al., 1995). Subadult survival (ages 1-5 years) is often higher compared to adult survival. Suggestion: A next version of the model could include more realistic agedependent mortality rates from literature data on other phocids.
3.2 ) One more detailed question: Why is survival (s) not assumed to be 1mortality (M) but s=exp(-M)? (See Page 15 ICES WGHARP REPORT 2016 submitted 141016) This procedure overestimates s survival a bit? For $\mathrm{M}=0.5 \mathrm{~s}$ becomes 0.60 , but the sum must be one. Suggestion: Correct or explain in the report.

Suggested test of the model: How rapidly does this model population increase with catches set to zero. Are the parameter values realistic? No seal population can increase more than about $10-12 \%$ and stay within known constraints of pinniped biology (Harkonen et al., 2002). One way to double check the settings is to incorporate the basic data in a Leslie matrix and study the growth rate as parameter by parameter is changed (e.g. Caswell 2011, Harding et al., 2002, Harding et al., 2007).

## B. Assumptions related to the catch

1 ) It is assumed that the age structure of the catch $1+$ is the same as the age distribution in the population $1+$. Is this a good assumption or is the sex and age ratio of the catches 1+ de facto likely to be biased? Any empirical data on this? If it is biased towards adult females, catches are more costly to the population (in terms of the effect on population growth rate) than the model suggests and consequently the applied hunting scenarios suggest that the population tolerate a too high hunting pressure. Suggestion: If there is information of the age and sex structure of the hunt we suggest this is incorporated in future modelling. Otherwise it can be investigated theoretically in the model (applying different test-structure of the catches systematically and record the effect on $r$ )

2 ) If age and sex structure is unknown we approve of the approach the WG takes to assume the age structure of catches of $1+$ to follow the age structure of the population flexibly for each year (eqn 4) as the baseline example.
3 ) The value of a pup for population growth rate relative to older seals is assumed to be 1:2. This simplification will underestimate the cost of the hunt
since adult females are worth about 2.7 for future population growth. The exact value will depend on the population growth rate and the values can be found by a Leslie matrix approach and its left eigenvector (Harding et al,, 2007).

## C. Model projections and catch levels

In the model projection the scenariocalled 'current catch levels" uses an average number of the last five years (average 7458 during 2012-1016). It is reported that continuing current catch levels (and with the assumed population parameter values above) we will see an increase by $58 \%$ in 15 years. This is however only a $3 \%$ annual growth rate in an exponentially growing population ( $\mathrm{N} 15=\mathrm{N} 0^{*} \mathrm{e}^{\wedge} \mathrm{r} 15$ ). $3 \%$ is not a safe growth rate for a pinniped population in models of risk assessment and does not allow for any other events not included in the model, such as failing food supply or an epidemic disease. A positive growth rate is a population's only guarantee from rapid decline and extinction. Thus the current catch level scenarioseems not sosafe. Also bearing inmind that multiple parameters included are chose at the higher end (all points mentioned above).
In this light, a hunt of $21500(100 \% 1+)$ animals in the so called Equilibrium Scenario (Table5) sounds very high and a sharp decline can be the result. Especially since population abundance estimates are poor it can take many years before a drop in population size can be documented. The RG advises that hunting should not exceed 7500 pups. How ever a new population assessment with revised approach is preferred, be fore any new catches are performed. Consequently, the RGalsosuspects that the catch option "Reduce to N70a" with a catch of 26000 (1+) animals will cause a sharper and quicker decline than projected.

## Conclusions

The harp seal biology in the Greenland Sea seems to be characterized by large long term fluxes in age at sexual maturity and pregnancy rate. Most likely these fluxes also affect annual survival rates (not included in the model). The WG has made an impressive job in constructing a model framework that make use of the pieces of information that exist. However, we are worried that parameterization at several points has been chosen in a way that happened to produce a too optimistic result of the potential harvest on this population. We give concrete suggestions for model improvements and test in the text above. Our recommendation is to systematically go through each parameter value withinitsbiologically realistic range and register its effect on the growth rate $(r)$ in a form of sensitivity analysis.

## For single-stock summary sheet advice:

Stock 5.1 The Greenland Sea Hooded Seal Stock
1 ) Assessment type: Population status assessed by modelling
2 ) Assessment:Historical abundance, reference levels, potential for catches
3 ) Forecast: No population forecast is presented.
4 ) Assessment model: Population projection model fitted to some empirical data on reproduction and catches. 2. Bayesian model fitting the population model to data on pup production, initial population sizes.
5 ) Consistency:

6 ) Stock status: Have undergone a dramatic decline during the last 70 years from about 1 M to about 80000 . Currentestimates of pup production show a continued decline.

7 ) Man. Plan.: Thehistorical hunt has been around 3 000-8000 annually since 1989 and up to 2006, thereafter a sharp drop in catches has occurred and the last years about 20 seals are hunted annually. The WG suggest no further hunting on this stock and the RG agree with this conclusion.

## General comments

This section on hooded seals is well written and gives a good background to the biology and historical catchlevels. However, the population is poorly studied and the lack of abundance and age structure/natural mortality data are striking. Nevertheless, the WG has made the best of the situation and produced a population model with parameter values of life history, catches and pup production tuned to hooded seals.

## Brief summary

The hooded seal is a top predator in the Arctic drift ice. Parameter values given in the report (pregnancy rate 0.7 , age at maturity about 6 years, mortality about 0.34 (pups) and 0.17 ( $1+$ ) indicate that the populationhas a very low intrinsicrate of increase compared to most phocid seals. Hooded seals seem to be one more of these slow growing top predators that are so easy to overexploit and also vulnerable to large-scale changes in prey abundance.
The estimated total 2017 population of hooded seals in the Greenland Sea is 80460 ( $95 \%$ CI59 020 - 101900 ). In the 1950s the population is estimated to have been around 1 M (Fig 5). An annual harvest of over 20000 seals during the 1970s most likely contributed to the stock collapse. The lack of recovery last years asjudged from pup production data are worrying and may indicate a change in the entire foodweb, as suggested by the WG. Estimated pup production was about 13000 in 2016 and in 1997 23000 pups.

## Technical comments

## A. The Population model and parameter values chosen

The same model as for the Greenland harpseal hasbeen used but parameters are chosen to mimic the hooded seal population. The RG approve of the general model approach. However, just as with the Greenland harp seals all conclusions depend on parameter values. This stock is not suggested to be further hunted and thus an improvement of the population model is not as urgent as for species that may be harvested. If for other management reason the hooded seal population dynamics is to be further understood the RG suggest a similar approach as we suggested for harp seals. Suggestion: Vary age at sexual maturity and pregnancy rates and assumed mortality rates among years according to a stochastic good year/bad y ear distribution with data on variability from the past and when necessary with data from other phocid species (to give biological realistic limits for parameters). Perform a Leslie matrix analysis and a sensitivity analysis to see how the intrinsic growth rate (r) depend on the life history parameters. This can guide future research on the population.

## Recommendations on catches

The RG full agrees with the WG: "All model runsindicate a population currently well below $\mathrm{N}_{\lim }$ ( $30 \%$ of largest observed population size). Following the precautionary approach framework developed by WGHARP (ICES2005), no catches should be taken from this population."

## For single-stock summary sheet advice:

Stock 4.3 The White Sea and Barents sea Harp Seal Stock
Short description of the assessment: extremely useful for reference of ACOM!
1 ) Assessment type:
2 ) Assessment: abundance, potential for catches
3 ) Forecast: presented (for future population size given different hunting regimes)
4 ) Assessment model: Population projection model fitted to some empirical data on reproduction and catches. 2. Bayesian model fitting the population model to data on pup production, initial population sizes.
5 ) Consistency:
6 ) Stock status: Estimated to 1408000 ( $95 \%$ CI1 251 680-1 564320) according to the model, a sharp decline in reproductive rates since 2003.
7 ) Man. Plan: Current harvest is practically null (9 adult seals in 2012 and no pups. 28 animals in 2016). Suggested quotas for equilibrium takes of about 10000 adult seals could be excessive due to the high growth rates used in the model contrasting with the low pup production since 2004, and the fact that this population is data-poor. Additionally, the reduction of the whelping habitat due to rapid decrease of suitable sea ice could further jeopardize reproductive success.

## General comments

This section summarize the existing data on the stock in a clear and well-structured manner. However, the data points are few and with large variances. A well thought through population model is used, however due to a likely error in parameterization and scattered data the model does not capture recent declining trends in pup production and the model results must be treated very cautiously. The RG have some points of concern.

1) The grow th rate used in the modelling ( $12 \%$ over 15 years) might be too high since annual variation in pregnancy rate and stochastic variation in pup survival is not included.
2 ) This stock is data poor, as also the WG points out.
3 ) Hunting (1+) is more costly for the population growth rate than the 1:2 ratio used especially if the population is declining. The estimated Equilibrium catch of 10090 might be too high since the current trend in pup production is not captured by the projection model. The RG agrees with the WG that better data on abundance, pup production and intrinsicrate of increase are required for future assessments.

## Technical comments

## A. The Population model and parameter values chosen

The population model used for the BarentsSea/White Sea harpseals is the same as the one used for the Greenland Sea population and we refer to the section on this population for detailed comments and suggestions for ways to improve the parameterization. We also express our concern in accordance with the WG that this population is data poor.

## Reproductive data

The model is fed tw o ty pes of reproductive data: maturity ogive and fecundity rate. A complete dataset for either of these parameters is not available for the whole period (1962-present). Fecundity is used with no variance and pregnancy rate is interpolated linearly for years with no data. WG expressed concerns about the uncertainty in pregnancy rates and the variations in fecundity rates. We agree with these concerns and confirm that the use of the last observed fecundity rate is not advisable. Suggestion: vary pregnancy rate in a stochasticfashion to mimicthe variability in harp seal reproductive data. It is also noted that age sexual maturity is very late in this population, we have here one slower growing late maturing Arctic marine mammal and a growth rate above $6 \%$ willbe highly unlikely. A Leslie matrix approach could be one way forward to obtainlikely life history values and growth rates $(r)$ (See for example Harding et al., 2002, 2007).

## Pup production values:

As pointed out by the WG data from commercial operations is unreliable and only surveys conducted in the period 1998-2013 canbe used. The latter also provide a measure of the variation in the data. Poor seaice conditions were observed in 2015 and 2016 which may have led to high pup mortality - particularly more during 2015 (See Page 19 ICES WGHARP REPORT 2016 submitted 141016). Data from this period are not included in the model and thus increased pup mortality in recent years has not been accounted for.

## Model estimates:

The model does not fit well to the early pup production, when data were not reliable, but does not fit either to the data from the later better surveys. Assuming the robustness of the model chosen these observations indicate that the life history data do not completely reflect the values for this population, and that some factors influence survival. Suggestion: Treat the model outcome with extreme caution.

## Catch levels:

The catch levels for the years since 2012 are assumed zero since the takes have been minimal. For the equilibrium catch to stabilize the population over 15 years only $1+$ animals have been considered. The resulting advice for equilibrium catch was 10090 animals $1+$. The RG noted that this advice is based on a too high intrinsic growth rate, it is reported that the population grow with $12 \%$ annually without hunting ( p 27 at the bottom). Suchhigh growth rates are only seen for pinnipeds with a sexual maturity at about 3 to 4 years, $95 \%$ pregnancy rate and $96 \%$ adult survival rates (thus unlikely for harp seals in the White Sea/Barents Sea.) This may also be the reason why the model is hard to fit to the pup production data involving an unexplained drop. The RG also
noted that the removal of adults only might affect the population more than a combination of adults and pups and more than 1:2 ratio. Suggestion: As above for modelling.

The request to provide advice on catch levels that would reduce the population toN70 w as not addressed using the model because of the lack of data, instead a PBR approach was provided. A precautionary recovery factor was employed and a simplified, adult/pup composition of the catch was assumed. The results were evaluated by the WG and deemed the approach not suitable, and the RG agrees.
Recommendation: The RG recommends no further hunting on this population until new data on pup production shows that declining trend has been broken. Furthermore, the RG suggest the population model to systematically test parameter values to find a realistic intrinsic growth rate, this might lead to better model fit, and new Equilibrium catch levels if any.

## Conclusions

The dramatic changes in ice conditions in recent years seem tohave had a strong influence on harp seal biology in the Barents Sea/White Sea and especially age at sexual maturity, pregnancy rate and pup production. The WG has made an excellent job in extracting useful data from the heterogeneous dataseries for use in the model framew ork. However, we are worried that the values chosen for the reproductive parameters and the pup production do not reflect the actual values mainly because this population is data poor. We pointed out some strategies for improvement of the model in the text above. We also recommend a precautionary approach when allocating a catch quota for this population which means no catches before a new assessment has been performed.
