## Work at Sea

The RV "Hinders" continued the monthly cruises off the Belgian coast on 14 stations to determine the density and the composition of juvenile soles, plaice, dab, flounders, gadoids, shrimps and other species.
The joint programe with Holland and Germany (demersal young fish survey) was continued by two cruises.
Work on fish
The stock analysis by means of market sampling was continued. Age, length, weight, sex and weight of the gonads of cod, whiting, plaice and sole were determined. The areas studied are as follows : Cod - North Sea, whiting - North Sea, plaice - North Sea, English Channel, Bristol Channel and Irish sea; sole - North Sea, Enelish Channel, Bristol Channel and Irish Sea.

| Area | Semson | No. of Samples |  | No. of Fish |  |

Canada
(A.W. May)

A fuller report on rescarch by Canada in 1973 on demersal fish species is contained in the Canadian research report to the Annual Meeting of ICIAF, May-June 1974.

Landings of the principal demersal species (cod, haddock, redfish, American plaice, greysole, yellowtail, Greenland halibut and pollock) from the IW Atlantic area by Canada in 1973 totalled about 500000 tons, some 15000 tons above the landings for the same species in 1972.

Landings of cod were lower in 1973 because of severe ice conditions in the northern area which hampered the traditional inshore cod fishery and because of a diversion of fishing effort to redfish in the Gulf of St. Lawrence. However, the decline in cod catches was more than offset by an increase in catches of redfish in the Gulf of St. Lawrence with mid-water trawls. Catches of pollock were greater than those in 1972.

In 1973, assessments were provided for the remaining cod stocks in areas from northern Labrador to the Scotian Shelf (ICNAF Subareas 2, 3 and 4); for the remaining American plaice stocks in ICNAF Subareas 2 and 3; for all major redfish and greysole stocks in ICNAF Subareas 2, 3 and 4; for all flounders combined in ICNAF Subarca 4; for silver hake in IGNAF Subarea 4; for the major Greenland halibut stock in ICNAF Subareas 2 and 3; for roundnose grenadier stock in ICNAF Subareas 2 and 3; for argentines in the southern part of ICNAF Subarea 4 and Subarea 5.

As a result of these assessments, international catch quotas for 1974 were agreed to by ICNAF for all stocks of demersal fish, which support directed fisheriess in ICNAF Subareas 2, 3 and 4.

To provide a data base for continued revision and updating of assessments for these demersal stocks, intensive research vessel surveys and commercial sampling of the various fisheries were conducted in 1973.

Associated biological data were collected for all species. Returns from tagging of yellowtail on the Grand Bank (Subarea 3) indicated limited movement from the area of tagging. Analyses of stomach contents of American plaice indicated that benthic invertebrates occurred more frequently than any other food type but that by weight capelin and sand launce were more important.

Studies on redfish were intensified in 1973 while studies on cod and haddock were conducted at the same level as in previous years.

## Denmark <br> (0....Bages)

## Plaice

In July and August quantitative fishery for 0-group plaice was carried out in the Kattegat and the Sound. In the northern Kattegat the catches were about averages in the middle Kattegat, the southern Kattegat and in the Sound well above average.
Haddock, Whiting and Cod
On the "Dana" cruise in February length measurements and otoliths were. collected.
Sole
The samplincs in Fay from the west coast of Jutland have been continued and an age/length key has been worked out.
Cod
Tagging of cod has been carried out in the North Sea off Thorsminde; in March 309 individuals more than 70 cm and 154 cod caught on the Monkey Bank werc tagged and transplanted to the Kattegat and released NV of Anholt.

551 cod were tagged in April and 569 in October in the Sound.

## Federal Republic of Germany

( 1 . Meyer)
Continuation of the biological studies at sea on research ships and the markets with length measurements, collection of otoliths; maturity data and food.
Research trips: January - North Sea; February - North Sea; February Baltic; April - North Sca, Baltic; May - North Sea, Baltic; Junc Baltic; August - Baltic; August-Soptenber - Faroc/Iceland Ridge; September - North Sea; October - Baltic; November - North Sea; Decenber - Baltic.

Sampling Data

## France <br> (G.Lefranc)

Travail on mer
En mars 1973, des cherchours embarqués à bord du NO "Thalassa" ont dresse dans le sud de la Mer du Nord, dans un secteur délimite par les meridiens $0^{\circ} 30^{\prime} E$ ot $5^{\circ} 30^{\prime} E$ et le parallele $54^{\circ} 30^{\prime}$ If un inventaire numérique des principales espèces commerciales (merlan, morue et poiscons plats) et établi les compositions on taillos ot on fges de ces captures. Les conséquences de l'utilisation de différents maillages ( 50,60 et 70 mm intéricur de maille) sur la composition des captures ont été étudiées; des coefficients de sélectivite déterminés par la méthode des traicts alternés; les perimètres thoraciques de 1091 morues ont été mesurés.

La "Thalassa" a d'autre part, prospecté en avril-mai les fonds de 200 à 500 m et plus, entourant Rockall, les accores nord de llecosse, le seuil Wyville Thomson, et le sud du Banc des Faeroe; de nombreuses donnees biologiques et biométriques concernant les espèees pêchées ot surtout la lingue bleue ont été collectés. Des facteurs de conversion poids plein, poids vide ont été calculés pour la lingue bleuc et le lieu noir.

## Travail au laboratoire

1. Laboratoire de Boulognc-sur-Mor

Parallèlement à l'étude des donnes et Échantillons recueillis au cours des campagnes, des relevés statistiques concernant les apports de licu noir, de merlan et de moruc sont poursuivis.

Une etude statistique et biologique du lieu noir en provenance de la Mer du Nord septentrionale, des Facroc, des accores ouept et des Shetlands et Hébrides a débuté courant 1973.

L'incompatibilité existant actuellement entre la taillo marchande du merlan fixbe à 23 cn et l'emploi du maillage réflenentaire de 70 mm a fait l'objet de plusieurs rapports.

L'etude de l'influence du maillage sur la qualite comerciale du merlan a trouve sa conclusion.

L'examen des premiers résultats obtenus à la suite des marquages de morue dans la rogion de Forty Miles montre que oes poissons s'éloignent très peu du licu de liberation et rostent pour plus de
 60 milles de rayon.
2. Laboratoire de Lorient

Merlan - poursuite du travail débuté en octobro 1972 sur lo morlan de la Mor d'Irlando : analyso du stock au moyon do l'echantillonnage des captures comerciales.

Liou noix, éflefin, noruc, sole - un roleve mensucl des captures des categories commerciales de ces différentes especes a été poursuivi.

## Iceland

## (J. Jónsson)

The research vessels""Bjarni Smundsson"and "Hafthor" were all the year engaged in work on demersal species. Besides work at Iceland, tho "Bjarni Sæmundsson" made two trips to East Greenland waters.

The distribution of the mature cod on its way to the spawning grounds and during the spawning was studied by means of echosounding, tagging and actual fishing on key positions. Besides that, the "environment" of the cod was studied by a dense net of hydrographical stations together with measurements of the phytoplankton production and the distribution and density of zooplankton.

The abundance of the immature population of cod on the nursery grounds mainly in the cold water area was studied by numerous trawling oxperiments and tagging.

The research programe described for the cod was also applied to the stock of haddock.

As for other demersal species, the investigations were carried out in more or less the sane way as in previous years. Of special interest was the pelagic trawling for redfish, but the results have until now been of negligible conomic importance.

The number of fish sampled is shown in the following table which deals with fish sampled from the comercial fishery and from rescarch vessel catches.

Sampling

## Ireland

(F.A. Gibson)

An intensive study of cod, plaice and black sole stocks in Irish waters was started in 1973.o The first few years of work with cod and black sole will be devoted to an understanding of the biology of these two hitherto unstudied species in our waters. In 1974s haddock uill be added to the three mentioned above.

Since 1970, a confined programme of research into the biology of skates, rays, blue shark, tope and monifish has been in progress, involving tagging, age, growth and analysis of food intake. Preliminary results suegest that skate and monkfish may be virtually sedentary; rays are essentially local in habitat; and that blue shark and tope wander over a wide area of the eastern Atlantic. Some evidence hes been found of thornback ray in certain bays of the west of Ireland, which though maturing at a size much smaller than those elsewhere recorded, never appear to grow as large as thornbacks in parts of Europe.

A limited tagging programe has been carried out with flounders: in the Irish Sea and this has enabled some growth and feeding data to be collected.

A routine rescarch vessel cruise to study whiting distribution. in the western Irish Sea was carried out in October 1973.

> Netherlands
(J. F. de Veen)

## Work at Sea

The RV "Tridens" made 14 cruises in the Comittee's area of which 11 were mainly or partly devoted to work within the scope of the Demersal Fish (Northern) Committee. The corresponding numbers of cruises by RV "Willem Beukels" were 23 and 12. The RV "Stern" and "Schollevaar" made together 23 cruises devoted to demersal topics in the Netherlands estuarics. The RV "Tridens", "Willem Beukelsz", "Stern" and "Schollevaar" made two joint cruises (in April and October) to analyse the stocks of juvenile sole, plaice, dab, flounder, gadoids, shrimp and other organisms in the nurserics of Belgium, Holland, Germany and part of Denmark in cooperation with the Belgian research cutter "Hinders" and the German RV "Neptun" and Büsum 45 "Hai".

## Work on Fish

## Plaice

The stock analysis by means of market sampling was continued. Analysis of the catches of the young fish cruises in the Southern and Central North Sca continental coastal areas revealed that the 1972 ycar class is poor and the 1973 year class of far above average strength.

Sole
The stock analysis by means of market sampling of soles from different localities in the North Sea, the Irish Sea, the ' $\because$ Bristol Chanincl was continued. One cruise in April was made to the Irish Sea and the Bristol Channel for census and tagging purposes. An analysis of the catches of undersized sole in the Belgian, Dutch and German coastal areaswas made in April and October in order to be able to predict commercial catches. Both year classes 1972 and 1973 appoared to be poor sp that we have now four year classes in succession since 1970 of below normal strength. A research programme on factors influencing recruitment to the North Sea sole stock was initiated. To this end a plankton sampling device for the bottom layers was developed and proved to be satisfactory in catching sole larvae and very small soles.

The following numbers of flatfish were tagged :
Sole: Irish Seas 1700 ädults, Dutch nurseries, 500 juveniles

## Plaice:

Flounder: Dutch nurseries, 1000 adults and i.: juveniles

## Cod, haddock and whiting

The stock analysis by means of market sampling was continued.
Cod
The year class 1972 appears to be good and the year class 1973 poor in the Central and Southern North Sea.

sampling data for Haddock

Norway
(A. Hylen)

## Subareas I and II

Fish sampling was carried out on the same scale as in 1972. Stock assessment programmes of Arcto-Norwegian cod and haddock, saithe and Greenland halibut have continued.

In February and March the distribution of Arcto-Norwogian cod in Lofoten was charted at three stages during the spawning season. Mature cod were tagged in March in the same area.

The distribution of young cod and haddock in the southeastern Barents Sea was charted in March during a survey of spawning capclin. In August the distribution and abundance of young cod, haddock and redfish was studied in the Vest SpitsbergenBear Island area and in the Barents Sca. In Scptember a survey of 0 -group fish of commercially important species was carricd out in the same area as part of the International 0-grour Survey.

Young saithe were tagged in June at the Norwegian coast in the southern part of Division IIa. Cods haddock and young saithe were tagged during August in the coastal waters of Northern Norway.

The abundance of 0-group saithe was studied in September at selected localities at the Morwegian coast.

Subarea IV
The sampling of commercial catches from the Recommendation 4 fisheries in Division IVa and the southern part of Division IIa was carried out throughout the whole year. A total of 124 landings from Division IVa and 83 from Division IIa were analysed.

Surveys of the distribution and abundance of the most important Recommendation species were undertaken in May, October, and November in Subarea IV.

Young saithe were tagged in Junc at the Norwegian west coast.

## Poland

(W. Cieglewicz and J. Netzel)

Baltic: The samples of cod; flounder and plaice were taken from landings.. Quantitative catches of juvenile cod were carried out in March on the RV "Dr Lukecki".

North Sea: The samples of cod, haddock, whiting and saithe were taken by the RV "Wieczno" and scouting vessels.

Northeast Arctic: The samples of cod, haddock, saithe and Greenland halibut were taken by scouting vessels.

Sex and sexual meturity were observed for all species mentioned on the enclosed table.

Portugal
(J. de Ataide and M. L. Dias)

The studies concerning this Committee's area were limited to samples of cod caught by the commercial fishing boats in the ICNAF area (Subareas 1 and 3). Data have been obtained on length, stage of maturity, age and age at first maturity (see table). Theyd are being processed for later analysis.

Spain<br>(0. Cendrero)

No relevant research was carried out except that in the ICNAF area.

Sweden
(G. Otterlind)

In the Baltic, investigations have been made on cod along the same lines as in previous years. The sampling for age determination comprises about 2000 fish. The abundance of cod eggs and larvae indicate a very good recruitment to the stock in the southern Baltic, but probably a poor one in the central Baltic proper.

## United Kingdom

1. Enpland and Wales
(D.J. Garrod)

## 1. Region I Fisheries

Stock assessment programmes have continued. RV"Cirolana" carried out five cruises in the area during the year. Three in the Northeast Arctic, a coding survey, 13 March - 3 April, in the S. Barents Sea, a survey of distribution of fish in the Bear Island, Spitsbergen, Hopen Island between 24 May - 20 June, and in August September a survey of the distribution of 0-group fish in the Barents Sea was undertaken as part of the international programme. One cruise was made to the west of Iceland where immunogenetic studies of cod were continued. At Faroe a survey of O-group fish was carried out at the beginning of July. 2. Region II Fisheries .

The programme of sampling commercial landings at all the major fishing ports was maintained at the same level as previous years, in addition a start was made on an intensive inshore sampling programme at many of the minor inshore fishing ports. The new programme is designed to give a more detailed knowledge of the abundance and distribution of the inshere stocks around the coast of England and Wales. The first phase of the programme covered the area between Flamborough Head and Eerwick on the N.E. coast and will be extended to cover the whole of the coastline.

This shore based programe was supported by a number of research cruises carrying out egg and larval surveys, tagging and trawl surveys to determine the seasonal distribution of the main commercial species.

In the central North Sea an 0-group gadoid survey was carried out in June as part of the international programme.

Two surveys to assess the commercial potential of the deep water grounds between 400 and 650 fathoms on the edge of the continental slope to the west of U.K. verc carried out during the yoar by RV "Cirolana" in April-May and by a chartered commercial fishing vessel "Swanella" during August-September. This work will continue in 1974.

## 2. Scotland <br> (R. Jones)

Scottish research vessels undertook routine trawling surveys in the North Sea in April/May and December. Surveys were also undertaken on the Scottish west coast in December and at the Faroes in July. The results of these cruises were used to obtain pre-recruit estimates of the year class strengths of haddock, whiting and Norway pout, and also to determinc the lengths and age compositions of the major demersal fish stocks. 0-group gadoid vere sampled pelagically in the North Sea in July with the object of obtaining carlicr estimates of their relative year.class strengths.

The major roundfish and flatfish species werc sampled at the principal Scottish trawl and seine net ports as in previous years. Samples were taken for age determination and these data form the basis for material supplied to Annales Biologiques and to ICES Statistical News Letters. They are also used to provide forccasts for the major Scottish fisheries.

Landings of Norway pout at the main Scottish ports were monitored throughout the year. Further Norway pout fecundity material was collected to determine the relationship between fecundity and size and to investigate variations in these parameters with density, and between areas.

Tagging of the major round- and flat-fish species has been continued with particular cmphasis on tagging in offshore Horth Sea waters.

Observations have been made on the movements and behaviour of a number of fish species by attaching ultrasonic transmitters to them and then following their movements by acoustic means. Preliminary results have shown that cod captured and released in a west coast sea loch, returned to their capture site within a matter of hours.

Aquarium studies have continued on the efficiency of food conversion in gadoids, and studies have been continued on the feeding bchaviour of gadoids.

Results of further examinations of whiting for Gilquinia and Anisakis infections have generally served to confirm previous findings. Promising preliminary results have been obtained from a new study of haddock populations using the larval costode Grillotia as a biolocical taf. The numbers of fish measured and aged in 1975 are shown in the attached tables.

In 1973, as well as in previous years, collection of material was conducted in the Barents, Norwegian, North and Greenland Seas by the Polar Research Institute of Marine Fisheries and Oceanography (PINRO). This work was aimed at determination of abundance, size-age composition and distribution of cod, haddock, saithe, redfish, Greenland halibut and other bottom fish in the ICES area. The volume of material by areas is shown in the following tables. The material was collected on board research vessels.

Besides, studies on the refinement of the assessment of the state of stocks of main commercial fish were continued; conditions of survival of the young at different stages of development were studied; ichthyoplankton was collected and analysed; fisheries forecasts were made; methods of forecasting were improved.

In spring and autumn 1973 trawl surveys on counting the young of haddock and whiting in the Northern Sea were completed by the Atlantic Research Institute of Marine Fisheries and Oceanography (AtlantNIRO). The spring ichthyoplankton survey on the haddock spawning grounds was also accomplished in the northwestern areas of the Sea.
Accumulation of material on size-age composition of haddock, whiting and saithe was continued.

In 1974 the study of early stages of haddock will be continued. Counting of young haddock and whiting; as well as study of the stock conditions for haddock, whiting and saithe is planned. The volume of the material collected and treated in 1973 is given in the Table below.

| Species | Masa moesurements |  | Age determination <br> (specimens) | Tagging (external hydrostatic tags) | Otoliths weighed |
| :---: | :---: | :---: | :---: | :---: | :---: |
|  | from fishing trawls (specimens) | small mesh cover (specimens) |  |  |  |
| Haddock | 191871 | 43603 | 824 | 3900 | - |
| Saithe | 78066 | 53 | 1948 | 800 | 1137 |
| Whiting | 63151 | 19949 | 1200 | - | - |

| Gadoid Fish | 28350 | - | 350 | - | - |
| Total | 395978 | 65575 | 5672 | 4-700 | 1137 |

Study of the reproduction conditions for $\operatorname{cod}$ and flounder in different areas of the Baltic Sea was conducted by the Baltic Research Institute of Fisheries. In 1973 the assessments were made on the yield, the birth and stock conditions for the 1971 to 1973 year classes. The regularities of stock distribution by areas werc investigated, special attention was paid to the peculiarities of growth and mortality for cod and flounder in relation to the environmental conditions and fishing intensity. Tagging of flounder and cod was carricd out.

Food chains of cod were studicd in the main feeding and reproduction areas as well as morphophysiological factorss the effect of the availability with food on the intensity of fat accumulation in fish organs the seasonal dynamics of fat, protein, carbohydrate and mineral metabolism in livers muscles and blood of the fish.

In 1974s these investigations will be continued.
