REPORT OF THE IRISH SEA AND BRISTOL CHANNEL WORKING GROUP Copenhagen, 17 - 25 April 1980

#### Abstract

This document is a report of a Working Group of the International Council for the Exploration of the Sea and does not necessarily represent the views of the Council. Therefore, it should not be quoted without consultation with the General Secretary.

x) General Secretary, ICES, Palægade 2-4, DK-1261 Copenhagen K, Denmark.

## 1. INTRODUCTION

1.1 Participation

The following members participated in the 1980 meeting of the Working Group:

| R J Boyd | United Kingdom |
| :--- | :--- |
| K M Brander | Unorthern Ireland) |
| A Charuau | United Kingdom |
| N Cloet | France |
| D de G Griffith | Belgium |
| (Chairman) |  |
| J Gueguen | Ireland |
| J P Hillis | France |
| P Sparre | Ireland |
| J F de Veen | Denmark |

W Panhorst attended the meeting as ICES Systems Analyst.
It is with sadness that we record the death of Joop de Veen in Copenhagen during the meeting of this Working Group. As a colleaggue his great contribution to the work of the Group will be missed and as a friend his humour and charm are irreplaceable.
1.2 Terms of Reference (C.Res.1979/2:40)

During the Statutory Meeting in 1979 it was decided that the Irish Sea and Bristol Channel Working Group should meet at ICES headquarters 17-25 April 1980 to:
(1) assess TACs for cod, haddock, whiting, plaice and sole in Divisions VIIa, VIIf and VIIg;
(2) continue the examination of interactions between fisheries.

### 1.3 Data Shortcomings

The continuing shortage of information on fishing effort, particularly from Ireland, hindered the Working Group in making the assessments requested from them. Biological data are still inadequate in many respects, particularly for the gadoid stocks in the Celtic Sea and the Working Group was unable to meet their terms of reference in this regard.
The availability of the catch data for the first time from the Isle of Man was welcomed by the Working Group. The Isle of Man catch data provided (which were for the year 1979) have been incorporated in the assessments.
In view of the rapid rise in total demersal landings in the Isle of Man (see Table l.l), efforts should be made to record all landings, rather than only those to processors, and to stipulate the nationality of the vessels involved.
2. IRISH SEA COD
2.1 Catch Trends

There was a rise of $33 \%$ in the catch of $\operatorname{cod}$ in 1979 to 8371 tonnes due mainly to increases in Irish and Northern Irish landings (Table 2.1). Landings in the Isle of Man have also been rising rapidly and have been included for the first time (see also Section 1.3).

The catch per unit effort on cod by French trawlers rose by $30 \%$ in 1979 and for English and Welsh trawlers by $7 \%$. Applying this to the total catch suggests that fishing mortality may have risen by as much as $24 \%$. The recorded number of hours of directed fishing on cod by Northern Irish trawlers fell by $29 \%$, but in view of the rise in their catch this seems unlikely to represent a decline in the fishing mortality in that fishery.

### 2.2 Age Compositions and Mean Weights at Age

The 1979 age composition was derived in the way described in the 1978 report. Discards and industrial landings have not been included, but are believed to be small as the industrial fishery ceased early in the year.

The Isle of Man landings have been raised using the English and Welsh age composition. The Northern Irish landings have been raised using the Irish age composition, but this may have led to an overestimate of the number of one and two year olds and an underestimate of the older fish, since the main Northern Irish fishery is on mature, spawning fish.
The values of weight at age remain unchanged from last year and the sum of products check is within $4 \%$ of the adult catch in 1979. This has been allowed for in the forecast calculations.

Values of weight at age are given in the text table below.

| Age | 1 | 2 | 3 | 4 | 5 | 6 | 7 |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| Weight (kg) | 0.61 | 1.66 | 3.33 | 5.09 | 6.19 | 6.76 | 8.30 |

### 2.3 Virtual Population Analysis

The relationship between catch per effort and number of one year olds (Figure 2.1 of last year's report) was used to estimate the size of the 1977 and 1978 year classes, and terminal $F$ values in the VPA were adjusted accordingly. In order to obtain the number of one year olds of the 1977 year class derived from catch per effort, the terminal $F$ on two year olds would have had to be l.33, which seems unrealistically high. As mentioned in Section 2.2, the number of two year olds in the catch may be overestimated but, nevertheless, there appears to have been a shift in the exploitation pattern onto one and two year old fish. This has a marked effect on the yield per recruit calculation.
In view of the variability in the exploitation pattern, a constant terminal $F$ of 0.8 was used on ages 3 and older. This gives a rise in mean $F$ of $27 \%$ between 1978 and 1979 and is about $30 \%$ higher than the level of $F$ during the early 1970s, which is consistent with the overall trends in fishing effort (Section 10). The resulting output is shown in Tables 2.2 to 2.5.

The trends in stock biomass are shown in Figure 2.1 and it appears that the decline in stock biomass has been halted in 1979 as is suggested by all the available catch per effort data. The small numbers of fish older than 7 are not included in the VPA, but have been added in the catch forecast.

### 2.4 Yield per Recruit

The yield per recruit curve conditional on the 1979 exploitation pattern is shown in Figure 2.2, and it shows a maximum at $40 \%$ of the present
level of F. Last year's curve showed a maximum at $50 \%$ of the 1978 level of $F$ even though the absolute level of $F$ was then thought to be much higher, at least on older fish. This difference is mainly due to the shift in the exploitation pattern. In view of the variability in the exploitation pattern, the possibility of interactions between species (Section 10) and the possibility of systematic effects of spawning stock on recruit level (see Appendix), it seems particularly undesirable to base a drastic management policy (e.g. severe reductions in TAC) on this yield per recruit curve alone.

### 2.5 Catch Forecasts

The recommended 1979 TAC was exceeded and fishing mortality may have risen (both last year's forecast and this year's VPA suggest that the rise was about $30 \%$ ). For the 1981 forecast it is assumed that fishing mortality in 1980 will be the same as in 1979; the catch in 1980 will thus be 7350 tonnes, leaving a total stock biomass of 15000 tonnes and a spawning stock biomass of 7000 tonnes at the beginning of 1981. For 1981 catches were calculated for three options of $F$ as shown below.

| Option | $\mathrm{F}_{1981}$ | Catch 1981 | Stock biomass 1982 |  |
| :---: | :---: | :---: | :---: | :---: |
|  |  |  | Total | Spawning stock |
| 1 | $=\mathrm{F}_{80}=\mathrm{F}_{79}$ | 7300 | 15000 | 7000 |
| 2 | $=0.8 \mathrm{~F}_{1980}$ | 6200 | 17000 | 8000 |
| 3 | $=F_{\text {max }}$ | 3600 | 21000 | 11000 |

The figures incorporate the $4 \%$ discrepancy in the sum of products check. Figure 2.3 shows catches and stock sizes for a range of fishing mortalities in 1981.

At least $50 \%$ of these forecast catches consist of one and two year old fish, for which average recruitment ( $5574 \times 10^{3} \mathrm{l}$ year olds) has been assumed.
There is a $5 \%$ joint probability that the two year classes will be as high as $12068 \times 10^{3}$ or as low as $2574 \times 103$, and the confidence limits which these values generate are shown in Figure 2.3. For Option 1 the catch in 1981 would be 7300 tonnes, but it could be as high as ll 600 tonnes or as low as 5300 tonnes. Conversely, if 7300 tonnes is actually caught in 1981 it could imply an increase of $70 \%$ in F or a decrease of $55 \%$. This once again illustrates that in these circumstances a TAC is not a very precise instrument for regulating fishing mortality.
Several young gadoid surveys have been carried out in 1979 in order to provide early estimates of year class strength and there is good evidence that the 1979 year class is in fact a big one. An abundant 1979 year class ( $12068 \times 10^{3}$ one year olds) would give a spawning stock biomass in 1982 of 11400 tonnes under Optionland of 18500 tonnes under Option 3. A comparison of the results of the 1979 United Kingdom groundfish survey with those of the previous three years suggests that the 1979 year class could be around this level of abundance.

### 2.6 Recommendation

The present level of $F$ is high in relation to the maximum of the yield per recruit curve and the stock biomass is still rather low. The Working Group, therefore, recommends Option 2, a TAC in 1981 of 6200 tonnes, but would once again stress the uncertainty of such a TAC achieving the desired level of fishing mortality.
3. IRISH SEA WHITING
3.1 Catch Trends

The total catch for 1979 was about 9900 tonnes (see Table 3.1), which represents a drop of $5 \%$ below the 1978 figure but virtually equals the 1979 TAC. There were no major changes in the share of individual countries but for the first time a catch figure for the Isle of Man was provided to the Group. The industrial fishery by Ireland stopped in April 1979. Available information on the Nephrops fishery discards (Section 9) was not adequate to use in the assessment. A significant quantity of whiting may also be discarded in the whitefish fishery.
3.2 Age Compositions and Mean Weight at Age

For 1979 England and Ireland provided catch at age data for the whole year. Northern Ireland provided similar information for the period August to December 1979. The Northern Ireland landings for the rest of the year were converted into age distributions by using an Irish ALK for the first two quarters. English ALKs were used to convert French length compositions into ages. The English catch composition was applied to the Isle of Man catches. The catch composition obtained by these methods represented $97 \%$ of the total to which it was then raised. For earlier years figures used were those presented in the 1979 Working Group report.
The weights at age were the same as those used in the 1979 stock assessment (see below). The sum of products check is low by $13 \%$.

| Age |  | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 | 9 |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| Weight at <br> age (kg) | Catch | 0.185 | 0.244 | 0.295 | 0.389 | 0.464 | 0.530 | 0.570 | 0.593 | 0.608 |
|  | Stock | 0.070 | 0.175 | 0.260 | 0.342 | 0.426 | 0.497 | 0.550 | 0.582 | 0.600 |

3.3 Virtual Population Analysis

The Working Group assumed that little change in effort had taken place since 1978. Input $F$ values were retained at least year's level. The results are given in Tables 3.2 to 3.5 . Neither the 1977 nor the 1978 year classes have been especially strong and the catch has accordingly declined by over $20 \%$ since 1977.
Stock biomass remained steady for the third year running at between 15.0 and $15.5 \times 10^{3}$ tonnes (see Figure 3.1).
3.4 Yield per Recruit

The yield per recruit and spawning stock biomass per recruit curves conditional on the 1979 exploitation pattern are shown in Figure 3.2. $F_{\text {max }}$ falls in the region of $40 \%$ of the 1979 F value.

### 3.5 Catch Forecasts

The number of 1 year old recruits in 1980, 1981 and 1982 was taken as $46 \times 10^{6}$, the geometric mean of the values for the period 1972-76.
Assuming that fishing mortality remains at its 1979 level in 1980, a catch of approximately 10000 tonnes should be taken, about 1000 tonnes below the recommended TAC. This will leave a total stock biomass of 17000 tonnes and a spawning stock biomass of 13000 tonnes at the beginning of 1981.
For 1981 catches were calculated for 3 options of $F$ as shown below.

|  |  |  | Stock biomass 1982 |  |
| :--- | :--- | :---: | :---: | :---: |
| Option | $\mathrm{F}_{1981}$ |  | Catch 1981 | Total |
| 1 | $=\mathrm{F}_{80}=\mathrm{F}_{79}$ | 9800 | 16000 | Spawning stock |
| 2 | $=0.8 \mathrm{~F}_{80}$ | 8400 | 18000 | 13000 |
| 3 | $=F_{\max }$ | 5400 | 21000 | 18000 |

The correction to allow for the $13 \%$ discrepancy in the sum of products check has been incorporated in these figures.
The results of these forecasts are summarised in Figure 3.3 which also shows the effect at two high and two low recruit levels.

### 3.6 Recommendation

The current levels of fishing mortality are high in relation to the conditional $F_{\max }$ and the Group recommends Option 2, a TAC in 1981 of 8400 tonnes. If a large amount of discarding has in fact been occurring, the reduction in F represented by this TAC may be much greater than $20 \%$. On the other hand, any continuing use of mesh sizes smaller than 70 mm would tend to counteract this effect.
4. IRISH SEA PLAICE
4.1 Catch Trends

The 1979 catch of 3390 tonnes showed a slight increase over the figures for the past two years (Table 4.1), and is to be compared with the Working Group's recommended TAC of 3000 tonnes (later amended to 2500 tonnes). The 1977 and 1978 catches were approximately $70 \%$ and $80 \%$ of the respective TACs for those years.

### 4.2 Age Compositions and Mean Weights at Age

The 1978 age composition was adjusted to take account of new data available from the United Kingdom. For 1979, age distributions were available from Ireland, England and Belgium, accounting for $86 \%$ of the landings. The total international age distribution was derived, for males and females (Table 4.2 and Table 4.6) in the same way as in previous years - Irish data raised to Ireland + Northern Ireland catches, English data to England + Wales + Isle of Man + Scotland, and the Belgian age distribution to the sum of Belgian, French and Dutch catches.

Mean weights at age were unchanged from previous years:

| Age |  | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 | 9 | 10 | 11 | 12 | 13 | 14 | 15 |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| Males | Catch | . 06 | . 173 | . 20 | . 27 | . 33 | . 37 | . 40 | . 43 | . 44 | . 45 | . 46 | . 46 | - | - | - |
|  | Stock | . 02 | . 09 | .17 | . 23 | . 30 | . 35 | . 38 | . 41 | . 44 | . 44 | . 45 | . 46 | - | - | - |
| Females | Catch | . 06 | . 14 | . 25 | - 37 | . 50 | . 63 | . 75 | . 86 | . 97 | 1.06 | 1.14 | 1.21 | 1.27 | 1.32 | 1. 36 |
|  | Stock | . 02 | . 09 | . 19 | . 31 | . 43 | . 56 | . 69 | . 81 | . 91 | 1.02 | 1.10 | 1.17 | 1.24 | 1.27 | 1. 34 |

The weights shown are in kg ; catch weight at age refers to 1 July and stock weight at age to 1 January. The sum of products check for 1979 was $14 \%$ too low, and an adjustment to take account of this has been made in the final catch forecast.

### 4.3 Virtual Population Analysis

Input Fs were derived by smoothing the mean values for the period 1971-75 given in the 1979 Working Group report. (This takes account of the increasing trend in fishing mortality since l97l, as indicated by the VPA.) The levels of $F$ on $l-$ and 2 year olds were adjusted to give approximately average (geometric mean) recruit strength in 1978 and 1979. Figure 4.1 shows a geometric mean regression of total stock biomass on United Kingdom cpue. The correlation coefficient is 0.539 ( $r=0.576$ for $p=0.05$ and 10 d.f.). The regression suggests that the total stock biomass for both the years 1978 and 1979 were among the highest on record, but the increase over 1977 as indicated by the VPA is only marginal (see Figure 4.2). However, the decline in stock biomass seems to have been halted in 1977.

The 1975 year class, which appeared to be very strong in the VPA's run in 1979 and 1978, now appears to have been only about average strength. The apparent strength of the 1976 year class should consequently be treated with reserve.

The results of the VPA are given in Tables 4.3-4.5 and 4.7-4.9.

### 4.4 Yield per Recruit

The curves of yield per recruit and biomass per recruit, conditional upon the 1979 exploitation pattern are shown in Figure 4.3. The combined male/female curves are weighted by the geometric mean number of recruits ( $6 \times 10^{6}$ males and $9 \times 10^{6}$ females). The conditional $F_{\max }$ is $35 \%$ of the peak $F$ in the 1979 exploitation pattern.

### 4.5 Catch Forecasts

The Working Group assumed that the fishery in 1980 would continue to be effectively unregulated by international agreement, and that the 1979 level of exploitation would continue. The catch for 1980 under these circumstances will be 3100 tonnes. The total stock biomass in 1981 will be 6000 tonnes and the spawning stock biomass will be 4600 tonnes. The 1980 TAC recommended by the Working Group in 1979 was 3000 tonnes, later amended to 2500 tonnes by the ACFM.

For 1981, catches were calculated for three options of $F$, as shown in the following text table:

| Options | $\begin{aligned} & F_{1981} \\ & \hline \end{aligned}$ | Catch 1981 | Stock biomass 1982 |  |
| :---: | :---: | :---: | :---: | :---: |
|  |  |  | Total | Spawning stock |
| 1 | $=\mathrm{F}_{80}=\mathrm{F}_{79}$ | 3000 | 5800 | 4100 |
| 2 | $=0.8 \mathrm{~F}_{80}$ | 2500 | 6300 | 4600 |
| 3 | $=F_{\text {max }}$ | 1300 | 7700 | 6000 |

The correction to allow for the $14 \%$ discrepancy in the sums of products check has been incorporated in these figures. It has also been applied to the values in Figure 4.4 which shows the 1981 catches and 1982 biomass corresponding to a range of fishing mortalities in 1981.

### 4.6 Recommendation

The present level of $F$ is high in relation to the maximum of the conditional yield per recruit curve, and stock biomasses still relatively low. The Working Group therefore recommends Option 2 and a TAC in 1981 of 2500 tonnes.
5. CELTIC SEA PLAICE (Divisions VIIf and VIIg)

### 5.1 Catch Trends

The 1979 catch was 863 tonnes, which is about the level of the last six years (Table 5.1). France continues to account for the major proportion of the total landings. Total French fishing effort in the area during 1979 was approximately the same as in 1978, but most of their effort is on roundfish. Belgian fishing hours (in the sole fishery, of which plaice is a by-catch) went down in 1979, but horsepower increased.
5.2 Age Compositions and Mean Weights at Age

The sum of the Belgian age distributions for Divisions VIIf/VIIg and the English age data for Division VIIf were raised to the total international catch (Tables 5.2 and 5.6). These two countries account for only $40 \%$ of the total catch.
Mean weights at age used were the same as last year ( kg ):

| Age |  | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 | 9 | 10 | 11 |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| Males | Catch | . 1 | . 236 | . 281 | . 305 | . 340 | .380 | . 428 | . 519 | - | - | - |
|  | Stock | . 1 | . 20 | . 26 | . 30 | . 32 | . 36 | . 40 | . 46 | - | - | - |
| Females | Catch | . 1 | . 286 | . 374 | . 467 | . 548 | . 705 | . 838. | . 949 | 1.109 | 1.409 | 1.600 |
|  | Stock | . 1 | . 24 | .33 | . 41 | . 51 | . 62 | . 78 | . 89 | 1.03 | 1.27 | 1.52 |

The sum of products check for 1979 agreed with the catch total.

### 5.3 Virtual Population Analysis

The 1978 values of $F$ were used as input for a trial VPA run. This gave an $18 \%$ drop in weighted mean $F$ from 1978 to 1979 which was not in accordance with the available data on fishing effort, and so the levels
of $F$ were raised by $10 \%$; $F$ on $I$ year olds was adjusted to give average recruitment. This still resulted in a reduced 1979
exploitation pattern on the younger age groups ( 3 and 4 year olds) and a $13 \%$ reduction in the weighted mean $F$ from 1978 to 1979. This output from the VPA is given in Tables 5.3 to 5.5 (males) and Tables 5.7 to 5.9 (females). The resulting trends in stock biomass and year class strength from 1970 are shown in Figure 5.1. Stock biomass has been declining slowly and now stands at about $60 \%$ of the 1970 level. However, the 1975 and 1976 year classes appear to be strong.
5.4 Yield per Recruit

The yield per recruit and spawning stock biomass recruit curves, conditional upon the 1979 exploitation pattern, are shown in Figure 5.2 for males, females and the sexes combined, (weighted by recruit strength). The conditional $F_{\max }$ is about $40 \%$ of the 1979 peak level of F .
5.5 Catch Forecasts

Recruitment was calculated as the geometric mean for the period 1970-76 i.e. $1.1 \times 10^{6}$ males and $1.3 \times 10^{6}$ females for 1980 , 1981 and 1982. Assuming that fishing mortality remains at its 1979 level in 1980, a 1980 catch of approximately 800 tonnes should be taken - a slight reduction on the 1979 catch and some 100 tonnes (14\%) above the 1980 recommended TAC ( 700 tonnes). This will leave a total stock biomass of 1900 tonnes and a spawning stock of 1200 tonnes at the beginning of 1981 (see Figure 5.1). For 1981, catches and stock sizes were calculated for three options of $F$ as shown in the text table below:

| Option | $\mathrm{F}_{1981}$ | Catch 1981 | Stock biomass 1982 |  |
| :---: | :---: | :---: | :---: | :---: |
|  |  |  | Total | Spawning stock |
| 1 | $=F_{80}=F_{79}$ | 700 | 1800 | 1100 |
| 2 | $=0.8 \mathrm{~F}_{80}$ | 600 | 1900 | 1200 |
| 3 | $=F_{\max }$ | 300 | 2200 | 1500 |

The results of these forecasts for a range of fishing mortalities in 1981 are shown in Figure 5.3.

### 5.6 Recommendation

The present level of $F$ is high in relation to $F_{\max }$ and projected stock biomass will decline in 1980 and 1981. The Working Group therefore recommends Option 2 and a 1981 TAC of 600 tonnes.
6. IRISH SEA SOLE
6.1 Catch Trends

The 1979 catch was 1629 tonnes, including landings from the Isle of Man. The official Irish and Dutch landing figures were amended to incorporate landings in the United Kingdom (Fleetwood). The 1979 catch was substantially $48 \%$ higher than in 1978 and in fact the highest since 1971. Catch rates of Belgium, Netherlands and United Kingdom went up by $80 \%, 32 \%$ and $52 \%$, respectively. Belgian effort remained roughly constant (beam trawl effort went up by $17 \%$ but otter trawl went down by 45\%) and Dutch effort (beam trawl) went up by 5\%. Total effort based on Belgian and United Kingdom catch per unit effort declined. The nominal catches in 1970-79 are given in Table 6.1.

### 6.2 Age Compositions and Mean Weights at Age

The international age composition was calculated by raising the Belgian, Dutch and United Kingdom age distributions accounting for $81 \%$ of the total catch, to $100 \%$. The age distribution of the provisional 1978 catch was amended (Tables 6.2 and 6.6 ) to correspond to the final catch figure to that year. The sum of products check using the weight at age data from last year's assessment shown in the text table was $3 \%$ too high. This discrepancy was left during the calculations and was only adjusted in the final catch forecast.

|  | Age | 2 | 3 | 4 | 5 | 6 | 7 | 8 | 9 | 10 | 11 | 12 | 13 | 14 | 15 |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  | Males | . 123 | . 151 | . 173 | . 195 | . 215 | . 232 | . 245 | .254 | . 264 | . 275 | . 283 | . 291 | . 299 | . 305 |
|  | Females: Catch | . 140 | . 195 | . 250 | . 300 | . 345 | . 390 | . 425 | . 460 | . 495 | . 520 | . 550 | . 575 | - 595 | . 615 |
| $\stackrel{0}{3}$ | Stock | . 120 | . 170 | . 220 | . 270 | . 310 | . 360 | . 410 | . 440 | . 480 | . 510 | . 530 | . 560 | . 580 | . 600 |

### 6.3 Virtual Population Analysis

The age composition of the 1979 international catch is dominated by the 1975 year class, as is also the case in the national catches of Belgium, the Netherlands and United Kingdom. Both in the male and female age compositions, $50 \%$ consists of this year class alone.
In last year's assessment the size of the 1975 year class was derived from the geometric mean regression of VPA 2 year old sole on Belgian cpue of 3 year old soles in the beam trawl fishery. The most likely values for the 1975 year class as 2 group were $37 \times 10^{6}$ for males and $58 \times 10^{6}$ for females ( $67 \%$ of the size of the good 1971 year class at age 2), and the terminal $F$ values for age group 3 in 1978 were adjusted by last year's Working Group to produce these values.
Stock biomass in last year's VPA showed a decline since 1971 which stopped in 1977, followed by a slight increase in 1978. The Belgian cpue correlated well with the stock biomass trend ( $r=.79$ ), but the United Kingdom cpue showed a less good fit ( $r=.54$ ).
This year a trial VPA using last year's terminal $F$ values completely changed the picture ('A' in Figure 6.1). In this VPA, stock in 1977, 1978 and 1979 increased sharply to a level higher than in 1971, which increase is not reflected in the Belgian and the United Kingdom cpue curves. The 1975 year class is in this case about twice the size of the 1971 year class at age 2 .
It is possible that fishing effort in 1979 concentrated on the 1975 year class and to study the effects of this, new VPAs were run with amended values for terminal $F$ for age group 4; case $B, 1.5 \times F_{78}$ on 4 year olds and case C, $2 \times$ F78. $B$ and $C$ in Figure 6.1 show the resulting stock biomasses and the size of the 1975 year class.

Case $B$ is considered to give the appropriate values of $F$, stock biomass and recruit strength. The stock of the 1976 year class as 2 year olds agrees with the figure derived from a geometric mean regression of VPA 2 year olds on cpue of 3 year olds one year later in the Belgian beam trawl fishery (Figure 6.2). The correlation coefficient is 0.68 for 7 degrees of freedom which is significant at the $5 \%$ level. The input level of $F$ on the 1975 year class in 1979 is in line with the fishing mortality values for that age group in earlier years.
Figure 6.3 shows the trends of stock and recruitment levels derived from this VPA, together with Belgian beam trawl cpue (2nd quarter of each year) and United Kingdom otter trawl cpue (March-September).

### 6.4 Yield per Recruit

Figure 6.4 shows the curves of yield per recruit and spawning stock biomass per recruit conditional upon the 1979 exploitation pattern. It may be seen that the stock is currently underexploited relative to $\mathrm{F}_{\max }$, but increasing the level of exploitation would not bring about any significant rise in the yield per recruit since the curve is flat-topped.

### 6.5 Catch Forecasts

Recruitment for 1980, 1981 and 1982 was taken as the geometric mean recruitment indicated by the VPA in the period 1970-76. For males this was $2.9 \times 10^{6}$ and for females $3.8 \times 10^{6}$.
It was assumed that as for other Irish Sea stocks, the fishery in 1980 will continue to be unregulated by international agreement and that the 1979 level of exploitation would continue. This will yield a catch in 1980 of 1600 tonnes, with a total stock biomass of 7400 tonnes and spawning stock of 6600 tonnes at the beginning of 1981. This catch compares with the 1980 TAC of 1300 tonnes recommended by last year's Working Group meeting.
For 1981, catches have been calculated for three options of $F$ in that year, as shown in the text table below. The correction to allow for the $3 \%$ sum of products discrepancy has been incorporated.

|  |  |  | Stock 1982 |  |
| :---: | :---: | :---: | :---: | :---: |
| Option | $F_{\text {1981 }}$ | Catch 1981 | Total | Spawning |
| 1 | $F_{81}=F_{80}\left(=F_{79}\right)$ | 1500 | 7000 | 6200 |
| 2 | $F_{81}=0.8 F_{80}$ | 1200 | 7300 | 6500 |
| 3 | $F_{81}=0.4 F_{80}\left(=F_{0.1}\right)$ | 600 | 7900 | 7000 |

The levels of catch and stock for a full range of $F$ values are shown in Figure 6.5

### 6.6 Recommendation

The stock is fully exploited in terms of conditional yield per recruit and there appears to be no justification for a reduction in fishing mortality. The Working Group therefore recommends Option 1 and a 1981 TAC of 1500 tonnes.
7. CELTIC SEA SOLE (Divisions VIIf and VIIg)

## Catch Trends

The total catch in 1979 rose slightly from its 1978 level of 780 tonnes to 954 tonnes which was $76 \%$ of the recommended TAC (l 250 tonnes). Although the 1979 catch represented a decline from the 1976 level of 1351 tonnes, it was still well below the 1970-73 values, which were in the 1300 - 1900 tonnes range. The change in 1979 was due to an increase in the Belgian catch from 506 tonnes in 1978 to 693 tonnes, the catch in France and the United Kingdom showing a very slight decrease (Table 7.l.A).
Total effort (calculated by raising Belgian beam trawl effort corrected for fishing power)showed a slight decline in 1979 (Figure 7.1).
7.2 Age Compositions and Mean Weights at Age

The age distribution for 1978 was the same as that used in the Working Group report for 1979. For 1979 only Belgian age distributions were available, covering $65 \%$ of the total international catch. They were raised to the total international catch and the sum of products checks were in good agreement (within $1 \%$ of the actual catch).
Mean weights at age in the catch and in the stock were the same as those given in the 1979 Working Group report (see below).
Weight at age (kg)

| Age | Catch weight |  | Stock weight |  |
| :--- | :--- | :---: | :---: | :---: |
|  | Males | Females | Males | Females |
| 2 | .133 | .200 | .120 | .168 |
| 3 | .187 | .282 | .174 | .258 |
| 4 | .217 | .377 | .217 | .377 |
| 5 | .276 | .435 | .276 | .435 |
| 6 | .305 | .516 | .305 | .516 |
| 7 | .339 | .574 | .339 | .574 |
| 8 | .363 | .632 | .363 | .632 |
| 9 | .388 | .730 | .388 | .690 |
| 10 | .423 | .757 | .423 | .732 |
| 11 | .436 | .787 | .436 | .757 |
| 12 | .448 | .798 | .448 | .787 |
| 13 | .459 | .823 | .472 | .798 |
| 14 | .472 | .847 | .484 | .823 |
| 15 | .484 | .497 | .835 |  |
| 16 | .497 |  |  |  |

### 7.3 Virtual Population Analysis

Inputs and outputs are given in Tables 7.2 to 7.9.
The exploitation patterns used as input were the same as those used in last year's report, but with the F values lowered by $10 \%$ to take account of the lower fishing effort exerted during 1979 compared with that of 1978 (see Figure 7.1). Although the VPA output (Tables 7.3 and 7.7) shows a slight increase in weighted mean $F$ on the mature age groups in 1979, it corresponds to the 1974 and 1975 levels when fishing effort
was at a similar level to that in 1979, as may be seen from Figure 7.1. The Working Group did not feel that a further reduction in input Fs would be justified.
Although the present VPA indicates that the 1976 year class was not as abundant (as 2 year old recruits) as last year's report suggested, it is still one of the strongest on record and lies on the geometric mean regression line of VPA 3 year olds against cpue of 3 year olds in the Belgian beam trawl fishery $(r=0.98$ and 0.97 , see Figure 7.2). Both correlations are highly significant. The 1977 year class also appears to be strong (Figure 7.2). The steep decline in spawning stock biomass (resulting from the steady disappearance of the strong year classes of 1959 , 1960 and 1963) was halted in 1977 (Figure 7.3), although total stock biomass was slightly lower in 1978 than in 1977.
7.4 Yield per Recruit

The yield per recruit curve conditional upon the 1979 exploitation pattern is flat-topped as may be seen in Figure 7.4, which also shows the corresponding curves for spawning stock biomass per recruit. The current level of fishing mortality is around $F_{0.1}$ on the combined male/female yield per recruit curve.

### 7.5 Catch Forecast

The input data are shown in Table 7.l0. Recruitment was calculated as the geometric mean recruitment for the period 1970-76, $1.9 \times 10^{6}$ males and $2.2 \times 10^{6}$ females. It was assumed that the level of fishing mortality would remain unchanged from 1979 through 1980, in which case the 1980 catch will be 1024 tonnes. This agrees with the recommended 1980 TAC of 1000 tonnes. The total stock biomass at the beginning of 1981 will have increased to 7700 tonnes and the spawning stock biomass will have increased to 7100 tonnes.
TACs for 1981 have been calculated for a range of $F$ values relative to $\mathrm{F}_{1980^{\circ}}$ These may be seen in Figure 7.5 , which also shows the resulting biomass for 1982. If fishing mortality in 1981 continues to be at the 1980 level, the catch in 1981 is calculated to be 1025 tonnes.

### 7.6 Recommendation

The Working Group recommends that the 1981 TAC should be 1000 tonnes, on the basis that this stock is optimally exploited in terms of the yield per recruit model.
8. OTHER GADOID STOCKS
8.1 Celtic Sea Cod

Cod catches in 1979 amounted to 3450 tonnes, which represents an increase of $25 \%$ over the 1978 figure. In both years, France accounted for more than $90 \%$ of the catch (Table 8.1).

### 8.2 Celtic Sea Whiting

For the fourth year in succession, catches are of the order of 6000 tonnes of which $56.9 \%$ were landed by France (Table 8.2). In 1978 and earlier years, catches were predominantly from Division VIIf but in 1979 about $62 \%$ of the total catch came Division VIIg.
Catch per effort data available for France ( $82.2 \mathrm{~kg} /$ ue in 1979) showed a drop of $35 \%$ below the 1978 figure for Division VIIf, whereas there
was no change in Division VIIg ( $106.8 \mathrm{~kg} / \mathrm{ue}$ ). As explained in last year's report, due to the lack of data for the years prior to 1977, no VPA could be run, but using French effort data, numbers by length group in the French catches for 1978 and 1979, and applying an English age/length key, a first estimate of the $Z$ at age in 1979 was made (see Table 8.3). The Working Group did not feel that the data were adequate to allow an estimate of stock size to be made and hence to recommend a TAC. Nevertheless, the fishing pattern on Celtic Sea whiting being similar to that of the Irish Sea, it may be inferred that the stock would benefit from a reduction in $F$ in 198l.
8.3 Haddock in the Irish Sea and the Celtic Sea

For the second year running, catches originating from Divisions VIIg-k are about 1000 tonnes, of which France accounted for $95 \%$ (Table 8.4). A more detailed split available for France in 1978 showed that only 370 tonnes of her catch was taken from Division VIIg.
No biological information on this species was available to allow the Working Group to make any recommendations. It is unlikely that such information will appear in the future and the Working Group repeats its proposal of last year that haddock in the Irish Sea and the Celtic Sea be omitted from its terms of reference.
9. BY-CATCHES OF PROTECTED SPECIES IN NEPHROPS FISHERIES
9.1 Irish Nephrops Fishery in Division VIIa

There is some evidence that in Division VIIa, Nephrops fisheries continue to catch whiting of a generally smaller size than directed gadoid fisheries (Table 9.1). This is due to several factors, including (l) the effect of Nephrops in the cod end on the selection factor for whiting (Hillis, $1962^{X}$ ) and (2) the persistance of some fishing with small-meshed nets in the area. Table 9.1 shows that the age structure of these whiting is generally lower and their length at age markedly lower than that of whiting caught in the directed whitefish fishery. The difference in age structure has not been allowed for in raising the Irish number at age because sampling is incomplete, having been carried out in only one quarter of the year. Examples of length frequencies of whiting catches (landings + discards) from a sector of this fishery believed to be poorly regulated are given in Table 9.2.

Owing to lack of adequate knowledge about the total quantity of whiting taken as by-catch in the Nephrops fishery, the Group was unable to quantify the effect of this by-catch on the whiting stock.
9.2 French Nephrops Fishery

No data are available concerning by-catches in the Nephrops fishery in Division VIIa.
x) Whiting mesh selection experiments in Irish waters. ICES, C.M.1962, Comparative Fishing Cttee, No.62.

In the Celtic Sea (Division VIIg, mesh size in use $55-60 \mathrm{~mm}$ ), a continuous sampling programme aboard commercial vessels was initiated in December 1979. Length composition data are given in Table 9.3 (representing 800 hours fishing), from the eight samples taken during the period December 1979 to March 1980.
For Nephrops trawlers from Brittany, protected species make up $20 \%$ of the total landings, Nephrops $65 \%$ and non-protected species $15 \%$. Amongst protected species, megrim is $6.6 \%$, cod $3.75 \%$ and whiting $1.2 \%$ of the total landings.

Catches of undersized fish are mainly of megrim on muddy bottoms in the Nephrops areas and to a lesser extent of hake on the Smalls grounds.
At present the sampling programme, which commenced in 1979, has not yielded sufficient information to allow any assessment to be made of the effect of by-catches of the stock of the by-catch species.
9.3 By-Catches of Protected Species in the Shrimp (Crangon) Fishery

Estimates of the numbers of plaice and sole taken as a by-catch in the English and Welsh shrimp fishery in the Irish Sea are available for 1979. They show that about $19 \times 10^{6} 0$-group plaice and $1.5 \times 10^{6} 0$-group sole were taken in a total shrimp catch of 500 tonnes. These fish are released again during different stages of the sorting process, and studies are in progress to estimate the level of survival. In order to incorporate these figures in the assessment it will also be necessary to estimate the natural mortality on 0-group and l-group plaice. Catches of other protected species are small.
10. MULTISPECIES MODELLING

### 10.1 Introduction

The Group considered recent developments in modelling species interactions and technical interactions in order to evaluate their likely importance in generating management advice and to make recommendations on the data which should be compiled. The purpose of the different types of model, their data requirements and the local difficulties in applying them to the Irish Sea are set out below. Present shortcomings in the data base needed for single species assessments should not be overlooked when moving on to these interactive models. In particular, we need better information on all the fishing-induced mortality not accounted for at present (e.g., discard mortality) and on the effort applied in all fisheries.
Ultimately the models which explicitly include species interactions and technical interactions should be used as the basis for fisheries management advice and the Group therefore considers it worthwhile to devote effort to their development in relation to the Irish Sea. Nevertheless, it may be some time before they can be applied and for the present the Working Group has continued with the surplus production model based on the total demersal catch. This is used to recommend the adoption of a total demersal TAC (Section 10.4).

### 10.2 Species Interaction (Legion Analysis)

Two recent papers (Pope, 1979* and Helgason and Gislason, 1979**) describe similar models which take predation-induced mortality into considera-

* A modified cohort analysis in which constant natural mortality is replaced by estimates of predation levels (Doc. C.M.1979/H:16).
** VPA analysis with species interaction due to predation (C.M.1979/G:52).
tion. These models are constructed as an extension of ordinary VPA and thus work on historical data. In Sparre, 1980 (to appear as an ICES paper this year) the model (known as legion analysis) is extended to allow for running it in the prognostic mode. To run the legion analysis, a number of additional parameters need to be estimated. and they are:

1) Yearly food intake per individual of each stock and age group assessed.
2) A food suitability matrix (for a definition see Anon., 1980*).

All major fish stocks of the area under consideration should be included in the assessment, including the relevant outputs of the Herring Assessment Working Group. It is especially important that all stocks of fish predators are considered. This condition is difficult to satisfy for the Irish Sea as no age composition data are available for several major fish predators (e.g., hake, dogfish, skates, rays and yellow gurnard).
Before an assessment based on legion analysis is used as the basis for fishery management, a stomach content survey like that suggested for the North Sea (Anon, , 1980*) should be implemented for the Irish Sea.
In spite of these difficulties the Group felt that it would be worthwhile to try an assessment based on legion analysis at next year's meeting, even though this will require educated guesses for a number of parameters.

### 10.3 Technical Interaction

The model by Sparre (1980) also attempts to describe the technical interaction between various components of the fishing fleets, i.e. to allow for the fact that most fisheries are mixed fisheries.

An implication of this approach is that TACs on the various stocks should not be determined independently of each other. By-catches of other species need to be taken into consideration in setting TACs in a mixed fishery.
To model technical interaction (in its simplest form) a number of parameters need to be estimated.
I. A division of the total international fishing fleets into components consisting of uniform vessels. (In this connection a "fleet" is to be considered as a management unit, in country/gear combinations).
2. A by-catch matrix:

[^0]| Species <br> Fleet | 1 | 2 | .... | S |
| :---: | :---: | :---: | :---: | :---: |
| 1 | b ( 1,1 ) | b ( 1,2 ) | -••• | $\mathrm{b}(1, \mathrm{~s})$ |
| - | $\stackrel{\square}{-}$ | $\stackrel{\square}{\bullet}$ |  | - |
| E | $b(e, 1)$ | $b(e, 2)$ | . . . | $b(e, s)$ |

$\mathrm{E}=$ number of fleets considered
$S$ = number of species considered
$b(e, s)=(F$ on species $s$ by fleet $e) /(F$ on target species of fleet $e)$
For each age group "F on species s by fleet e" is defined as:
(Total $F$ on species $s$ ) $x \frac{\text { catch of species } s \text { by fleet } e}{\text { total catch of species } s}$
Total $F$ is derived from VPA.
Thus, the coefficients $b(e, s)$ are derived from species and age group compositions from the various fleets, output from VPA and information on target species.
3. Gear selection curves for each species for each fleet fishing on it. (Mesh sizes, selection factors).
4. Numbers discarded per year at each age group for each fleet and stock.

Technical interaction may well have a greater influence on management strategy than species interaction, and the Group gave the highest priority to modelling technical interactions. It may in any case be easier to estimate the parameters needed for the technical interactions than those for the species interactions and assessments incorporating technical interactions should be attempted next year.
A major difference between the North Sea and the Irish Sea is the relative importance of Nephrops in the latter area. This species must be included in the model of both technical and species interactions in the Irish Sea.

### 10.4 Total Demersal Production Model

The theoretical background and method of calculation of the total demersal model is given in the 1978 and 1979 Working Group reports. The data for 1977 and 1978 have been corrected and provisional figures for 1979 added to the time series (Table l0.1).
The total demersal catch again declined slightly to 44700 tonnes and fishing effort was almost unchanged at 13500 standard units. This level of effort is between $12 \%$ and $26 \%$ above the level for MSY, depending on whether the linear or the exponential model is preferred (Figure 10.1).

A $10 \%$ reduction would bring fishing effort to the MSY point on the Schaefer curve. This corresponds to a total demersal catch in 1981 of about 40000 tonnes for Divisions VIIa and VIIf, on the assumption that cpue remains at the level of the last four years ( 3.25 tonnes per standard unit). Out of this total demersal catch 29000 tonnes should be from Division VIIa.
The Working Group therefore recommends total demersal TACs for 1981 of 29000 tonnes in Division VIIa and 11000 tonnes in Division VIIf.

The advantages of using the surplus production model and of adopting a total demersal TAC are:

1. It is a yield model rather than a yield per recruit model. The conclusion from several single species yield per recruit models that fishing mortality should be reduced by large amounts may be misleading because they do not allow for interaction between species or for stock/recruit relationships.
2. The total demersal TAC would be a second-tier TAC, and would include the single species TACs. It thus provides a means of preventing diversion of effort onto non-quota species.
3. Although the present proposal is for a catch limitation rather than an effort limitation it should be seen as an aid to management since it focusses attention on the broad overall pattern and level of fishing required to exploit the available resources. Such an overview tends to get lost in individual species assessments.

The total of the proposed catch levels in Division VIIa in 1981 for the four demersal quota species is 18500 tonnes which represents $65 \%$ of the proposed total demersal TAC.

# APPENDIX: COD RECRUITMENT 

## by

K M Brander

The available data on spawning stock biomass and number of recruits from the 1979 Working Group report are given in Appendix Table l and plotted in Appendix Figure 1. Over the nine-year period covered, the highest recruitment occurred at the lowest spawning stock biomass (in 1970) and the lowest recruitment coincided with highest biomass (in 1973), which suggests a high degree of overcompensation in the stock/recruit relationship. Three curves have been fitted in Appendix Figure 1 using the equation and method described by Shepherd (in press):

$$
R=a B /\{1+(B / K) \beta\}
$$

The value of a (l 400 recruits/tonnes) is the slope of the line drawn to the left of the data points and it represents the maximum level of recruitment in the absence of density dependent effects. Conversely, if the biomass per recruit falls below $714 \mathrm{~g}(=1 / \mathrm{a})$ then the stock can no longer replace itself and collapses.

The value of $K$, the so-called 'carrying capacity' parameter, is derived from the average spawning biomass and average recruitment using the equation

$$
K=B^{*} /\left\{\left(a B^{*} / R^{*}\right)-1\right\}^{1 / \beta}
$$

This means that all the curves pass through ( $B^{*}, R^{*}$ ), the joint mean and the subsequent yield curves also have a common point. Although $K$ depends on $\beta$, the level of $F$ needed to generate $K$ is independent of $\beta$.

The value of $\beta$ represents the degree of compensation and the effect of choosing three different values of $\beta$ can be seen in Appendix Figure 1. When $\beta=1$ the curve produced is the Beverton-Holt asymptotic relationship and as $\beta$ increases the curve becomes increasingly dome-shaped. The choice of a value for $\beta$ is largely subjective but of the three values chosen here ( $1,2,5$ ) the highest has the lowest sum of squares ( $125 \times 10^{6}$, $93 \times 10^{6}$, $90 \times 10^{6}$ respectively). A value of $\beta$ as high as 5 is however unlikely on theoretical grounds.

The fitting of such a stock/recruit relationship is somewhat arbitrary and is liable to criticism on account of the small quantity of data, particularly at low stock levels, and because of the possibility of other systematic effects being present. For example, the reason for the high stock level in 1973 is of course the good recruitment in 1970 and any factor (e.g. temperature variability, slow environmental change) which causes recruitment to show systematic trends may give the mistaken impression that stock is primarily responsible.

An attempt was made to extend the data series back to 1961 using catch per effort instead of VPA. The data are given in Appendix Table 1 and plotted in Appendix Figure 2. The correlation between year class size from VPA and from cpue (number/100 h of 2 year olds) is very good ( $r=0.92$ for 8 df ), but the biomass series do not correlate well, mainly because
cpue was high in 1968-69 but VPA biomass was not. It is conceivable that cpue is in fact a better indicator of spawning stock biomass than VPA because the cpue data are for the spawning areas during the spawning season only and may therefore more truly reflect the amount of spawning taking place. In any case Appendix Figure 2 shows a relationship between stock and recruitment which is fairly similar to that in Appendix Figure 1. Mean values of recruitment have been calculated for three levels of spawning stock biomass and indicate that recruitment was lower at the low stock levels of 1961-63.

The effect of the three different $\beta$ values in Appendix Figure 1 on the yield curve is shown in Appendix Figure 3, which also shows the yield per recruit curve multiplied by $R^{*}$. This illustrates the enormous effect which the particular shape selected for the stock/recruit relationship may have on the yield curve and hence on the selection of a management objective. Since the available evidence indicates that recruitment may well be higher at intermediate levels of spawning stock, the current management policy of trying to reduce $F$ to 0.5 may be mistaken. On the other hand,recent values of $F$ have approached the level (about l.4) at which biomass per recruit may fall below the compensation level $357 \mathrm{~g}=\frac{1}{2} \mathrm{a}$ ) and should certainly be restrained from going any higher. Even if one accepts the curve for $\beta=5$, which gives MSY for an $F$ value of 1.8 , the population should not be exploited above an $F$ of 1.4 because of loss of resilience and the increased likelihood of stock collapse. The 'compensation $F^{\prime}$ value of 1.4 is independent of $\beta$ and therefore fixed whichever shape one chooses for the curve, but it does depend on the slope of a, which is also somewhat arbitrary. The compensation stock biomass also depends on $\beta$ and has the values 7026 tonnes, 9932 tonnes and 12220 tonnes for $\beta=1,2$ and 5 respectively.

If, as appears possible, the Irish Sea cod do indeed show some degree of overcompensation (i.e. lower recruitment at high stock levels) it is interesting to speculate on the cause of this phenomenon, since extensive sampling of their feeding habits shows no evidence of cannibalism at all.
