1 INTRODUCTION

Fisheries independent beam trawl surveys using research vessels were established in the 1980s by countries bordering the North Sea to monitor stocks of plaice and sole. Collation and analysis of some of the data derived from these surveys was undertaken by the Beam Trawl Study Group, which in 1998 was re-established as the Working Group on Beam Trawl Surveys. Although the initial focus of its efforts was in the North Sea and Eastern Channel, the Working Group now evaluates all major surveys in Sub-area IV and VII (ICES 1991).

The Working Group comprises regular participants from Belgium, Germany, Netherlands and the UK. An annual report describing the surveys and summarising the distribution and catch rate of fish species has been produced every year since 1990. Recent reports have described the distribution of selected species of benthic invertebrates.

1.1 Terms of Reference

At the 1998 Annual Science Conference it was resolved that the Working Group on Beam Trawl Surveys (Chairman: Dr S I Rogers, UK) should work by correspondence to:

- a) Prepare a progress report summarising the results of the 1998 Beam Trawl Surveys;
- b) Continue work of developing an international database of beam trawl survey data;
- c) Calculate population abundance indices by age-group for sole and plaice in the North Sea, Division VIIa and Divisions VIIId-g;
- d) Present summary results from other International Demersal Young Fish Surveys, including the pre-recruit indices for commercially important species;
- e) Collate information describing epibenthic invertebrate by-catch during beam trawl surveys;
- f) Obtain peer review of the Working Group report from the appropriate assessment Working Group prior to the 1999 Annual Science Conference;
- g) Comment on the draft objectives and activities in the Living Resources Committee component of the ICES Five-Year Strategic Plan, and specify how the purpose of the Working Group contributes to it.

The Working Group will report to the Living Resources and Marine Habitats Committees at the 1999 Annual Science Conference and to ACFM before its October 1999 meeting.

Willy Vanhee	Belgium

2 PROGRESS DURING 1998 AND SUMMARY RESULTS

2.1 Survey details

Beam trawl surveys described in this report cover an area comprising the southern North Sea (IVb, IVc), the English Channel (VIIId, VIIe), the Celtic Sea (VIIIf, VIIg) and the Irish Sea (VIIa). The gears deployed by research vessels in these areas are different because of differences in substrate type and the ability of vessels to deploy the trawls. Despite these differences, the survey and data analysis procedures are standardised, and have been described in detail elsewhere (ICES 1993; ICES 1994; Rogers *et al.* 1997). A summary description of the beam trawl survey characteristics of each

country is given in Table 2.1, and the duration of each survey is shown in Table 2.2. The total number of beam trawl hauls by these surveys is shown by rectangle in Figure 2.1, both for 1998, and for all years from 1990.

Sampling stations are stratified according to ICES rectangle and depth zone. In the UK surveys of the Channel and western UK waters, the station grid comprises fixed station positions, identified as Prime Station Numbers. In the Netherlands survey the stations are distributed pseudo-randomly over the rectangle, taking untrawlable areas into account.

Length stratified otolith samples of sole, plaice and dab are taken by sub-area. In the UK surveys the position of all otolithed fish is recorded but in North Sea surveys pooled samples are taken from hauls within otolith sampling areas. These sampling areas are shown in Figure 2.2.

2.2 Sampling procedures.

All surveys sample fish and selected species of macro-benthic invertebrates. A detailed description of sampling procedures has been produced in earlier reports of the Study Group (ICES 1990; ICES 1991; ICES 1993; ICES 1995), and also in journal papers published by members of the Group (Rogers *et al.* 1997; Rogers *et al.* 1998; Rogers *et al.*, 1999). In summary, all fish are sorted from the catch, identified and the number of fish by one cm size class is recorded. Large catches are subsampled. Catch rates were converted to the standard 8 m beam trawl by multiplying the observed catch rates by the ratio of the beam trawl widths, and raising to a one hour tow duration. A list of all demersal fish species caught since 1990, and all macro-benthic invertebrates caught in UK and RV Tridens surveys since 1997, is shown in Table 2.2.1 with Latin name and 3 letter NODC code. These NODC codes are used in the database as the SPECIES variable.

2.3 Fish distribution and abundance in 1998 (TOR a)

The catch rates of fish from the 1998 beam trawl surveys (numbers/8 m beam/hour) were averaged by rectangle, and these averages were averaged for the sub-areas shown in Figure 2.3. The data for selected fish species are presented by management area and year since 1990, and by ICES rectangle (Tables 2.3.1 to 2.3.9; Figures 2.3.1 to 2.3.26). A thorough process of checking and validation for earlier years' data has enabled some countries to provide improved datasets for the period 1990–1998. New time-series data have therefore been produced for the relevant management areas, but these improvements do not significantly change previously published data.

2.4 Survey indices of sole and plaice (TOR c)

Year class strength indices of sole and plaice (0-group to 10+-group), for the period 1985 to 1998, are provided for the Netherlands and UK surveys by management area (Table 2.4.1 and 2.4.2). The geographic coverage of each management area is shown in Figure 2.3. Each survey index is calculated as the arithmetic mean abundance over a standard grid of rectangles, and data are presented here for:

North Sea	(IVa)
Eastern Channel	(VIIId)
Western Channel	(VIIe)
Bristol Channel	(VIIIf&g)

2.5 Other International Demersal Young Fish Surveys (TOR d)

A number of other beam trawl surveys regularly report abundance indices of sole and plaice to ICES, but these are not part of the Working Group database, and are not used for calculating abundance indices described in section 2.3 above. The Demersal Young Fish Survey (DYFS) is a group of national surveys carried out by the Netherlands, Belgium and Germany in the continental nursery areas of the North Sea to record abundance of 0- and 1-group plaice and sole. A comparable survey is carried out by the UK on the flatfish nursery grounds of the North Sea (UKYFS). The Sole Net Survey (SNS) is a survey undertaken by the Netherlands to obtain pre-recruit indices for 1- and 2-group plaice and sole in coastal waters between the Scheldt estuary and Denmark. These surveys are described in further detail elsewhere (Beek 1997; Riley *et al.* 1981). Abundance indices for 0- group to 3-group sole and plaice produced by these surveys are shown in Table 2.5.1 a) to c).

It is appropriate to consider whether these survey data, and those from other European beam trawl surveys, should now be included in the routine output of WGBEAM. While this would be an important step forward, the time involved in collating and checking the data should not be underestimated.

2.6 International Beam Trawl Survey Database (TOR b)

The main purpose of the Group in the past 12 months has been to provide the wider scientific community with access to data from the beam trawl surveys. Although annual summary reports have been provided by the Group since 1990, and selected data published in scientific journals, it was felt that the major national survey datasets should be combined centrally by the Chairman of the Working Group, as a first step to preparing a formal database.

After some discussion it was decided that the basic format of using a separate trawl data file and fish length frequency file was to be adopted, following the principles of the International Bottom Trawl Survey database. The specification of these files has already been described (ICES 1996), but some modifications have taken place during the past 12 months. The agreed basic procedures and responsibilities are as follows:

- a) Data for each country is provided by the chief scientist of the relevant cruise.
- b) The responsibility for checking accuracy of entries and completeness of datasets remains entirely with the source country.
- c) The role of the Working Group Chairman is only to combine annual datasets and make the resulting compilation available.

During the past 12 months the Working Group has compiled a standardised dataset for the period up to and including 1998, and this is described in the following section.

2.6.1 Format of the International Beam Trawl Survey Database

Data are available for six countries for a maximum period of 9 years (Table 2.2).

In the database, data for each country is saved in a separate directory. For each country, data is saved separately for each year. For each survey year, data is separated into two files, one containing fish length frequency data (Table 2.6.1), and one for trawl details (Table 2.6.2). These two files can be combined using three variables common to both datasets, STATION, COUNTRY, and YEAR. Fish species length frequency data is presented by 1 cm length categories, raised to the catch / 8 m beam trawl / hour (Table 2.6.1). The SPECIES variable uses the three letter NODC codes common to ICES countries, and shown in Table 2.2.1 for all demersal fish species caught since 1990, and all macro-benthic invertebrates caught in UK and RV Tridens surveys since 1997. The beam trawl station position file (Table 2.6.2) includes important variables that are relevant to the position of the tow, and the prevailing sea conditions during the survey.

The Database consists of data stored in the format described in Tables 2.6.1 and 2.6.2. This format has been kept as simple as possible, and without restriction on the length of each variable. Data are submitted to WGBEAM as plain data or comma separated files (*.csv), and are subsequently held in the database both a SAS (version 6.12 MS DOS) format and as comma separated files, to allow easy export to different software. All files, including the text, tables and figures of this report, are stored on CD ROM. These data are held by all contributing countries, and are available to other scientists depending on their region of interest.

It is recommended that this format is adopted as standard when submitting data to the WGBEAM Chairman.

Additional information on fish age, and maturity at length, is also available for some species from the surveys but has not yet been included in the database. This will be considered as a possible subject of future investigation by the Working Group.

2.7 Analysis of benthic species distribution (TOR e)

Many invertebrates are caught as bycatch on beam trawl surveys. The level of sampling varies depending on the gear and type of vessel used, but the larger, epibenthic invertebrates are generally all identified and their abundances recorded. The less frequently observed, and smaller, epibenthic species do not form part of the database, but standardised sampling methods for this part of the biota are now becoming established by the UK and The Netherlands. There is still much that needs to be done by the Working Group to set quality standards for species identification, and to

describe the main species that need to be recorded. The main invertebrate species routinely sampled are given in (ICES 1994), and all epibenthic invertebrates identified since 1997 by the UK and The Netherlands are shown in Table 2.2.1.

The distributions of nine selected epibenthic invertebrates, which include species with predominantly either northern and southern distributions, are shown in Figures 2.7.1 to 2.7.9. The shaded region in these figures represents all rectangles comprehensively sampled for epibenthic invertebrates. It is clear that several species are widespread throughout the shelf seas of Northwest Europe, and that sampling the beam trawl bycatch for these species appears to be an effective way of collecting data on their relative abundance. Future studies will need to investigate the catchability and gear efficiency of beam trawls before conclusions can be drawn from the regional differences in invertebrate species distributions. These preliminary results suggest, however, that the groundfish surveys can provide valuable information for some macro-invertebrates.

3 COMMENT ON THE DRAFT OBJECTIVES AND ACTIVITIES IN THE LIVING RESOURCES COMMITTEE COMPONENT OF THE ICES 5-YEAR STRATEGIC PLAN.

The ICES scientific objectives, which incorporate the activities of the Living Resources Committee, include broad topics which are of relevance to the purpose and objectives of WGBEAM. Specifically, two of these scientific objectives refer to the need to understand the functioning of the natural ecosystem, and also to describe and quantify the effects of human impacts on these natural resources. Initially, the groundfish surveys which comprise the database of WGBEAM were established only with the purpose of monitoring the flatfish stocks of the coastal waters of north-west Europe. It has become clear, however, that all ICES member countries must justify the relatively high cost of sea time, and so the use and interpretation of additional information collected during these surveys has become an increasingly important output. Although the surveys were not designed to sample macro-epibenthic bycatch, for example, the data collected has real value and importance, and with careful interpretation can lead to real progress with the understanding of natural processes in the marine environment. The productivity of this working group, in terms of both annual WG reports and published scientific papers, shows how valuable a resource these groundfish surveys are.

The ICES 5-year plan makes it clear that understanding natural processes, and the effect of human impact on these processes, will be a fundamental part of its research. The broad scale fisheries sampling programmes of member countries are a valuable resource, and can make a real contribution to this research. For this to happen within the next five years, it will be necessary for this potential to be fully realised.

Table 2.6.1

Variables in fish length frequency file

variable	type	label	format
STATION	Char	Station number	
COUNTRY	Char	Country	
YEAR	Num	Year	19**
SPECIES	Char	3 letter NODC code	see Table 2.2.1
SEX	Char	sex	M, F, U,
CTCHNOHR	Num	Catch number / hour / 8m beam	
CTCHWTHR	Num	Catch weight / hour / 8m beam	kg
LENGRP	Num	Length group	cm
LENNOHR	Num	Number at length / hour / 8m beam	
SHIP	Char	Ship	
RECTAN	Char	ICES square	
PRIMSTN	Char	Primary station	English data only

Table 2.6.2

Variables in trawl station details file

variable	type	label	format
STATION	Char	Station number	
COUNTRY	Char	Country	
YEAR	Num	Year	19**
QUARTER	Num	Quarter	
MONTH	Num	Month	
DAY	Num	Day	
TIME	Num	Shot time	for example "1035"
SHIP	Char	Ship	
GEAR	Char	Gear type	see Table 2.1
PRIMSTN	Char	Primary station	English data only
HALDUR	Num	Haul duration	in minutes
HALLAT	Num	Haul Latitude	Decimal
HALLON	Num	Haul Longitude	Decimal
SHTLAT	Num	Shot Latitude	Decimal
SHTLON	Num	Shot Longitude	Decimal
DISTANCE	Num	length of haul	metres
DAYNIGHT	Char	Day / night	D, N
DIVISION	Char	ICES Division	
RECTAN	Char	ICES square	
SHTDEP	Num	Shot depth	metres
SFSALN	Num	Surface salinity	ppt
SFTEMP	Num	Surface temperature	deg C
WIND	Char	Wind direction & speed (Beaufort scale)	for example "SW10"
VHAULS	Char	valid haul	V, P, I

Figure 2.1 Total number of beam trawl hauls per rectangle.
 Total hauls in 1998 (above) and total for 1990–98 (below).

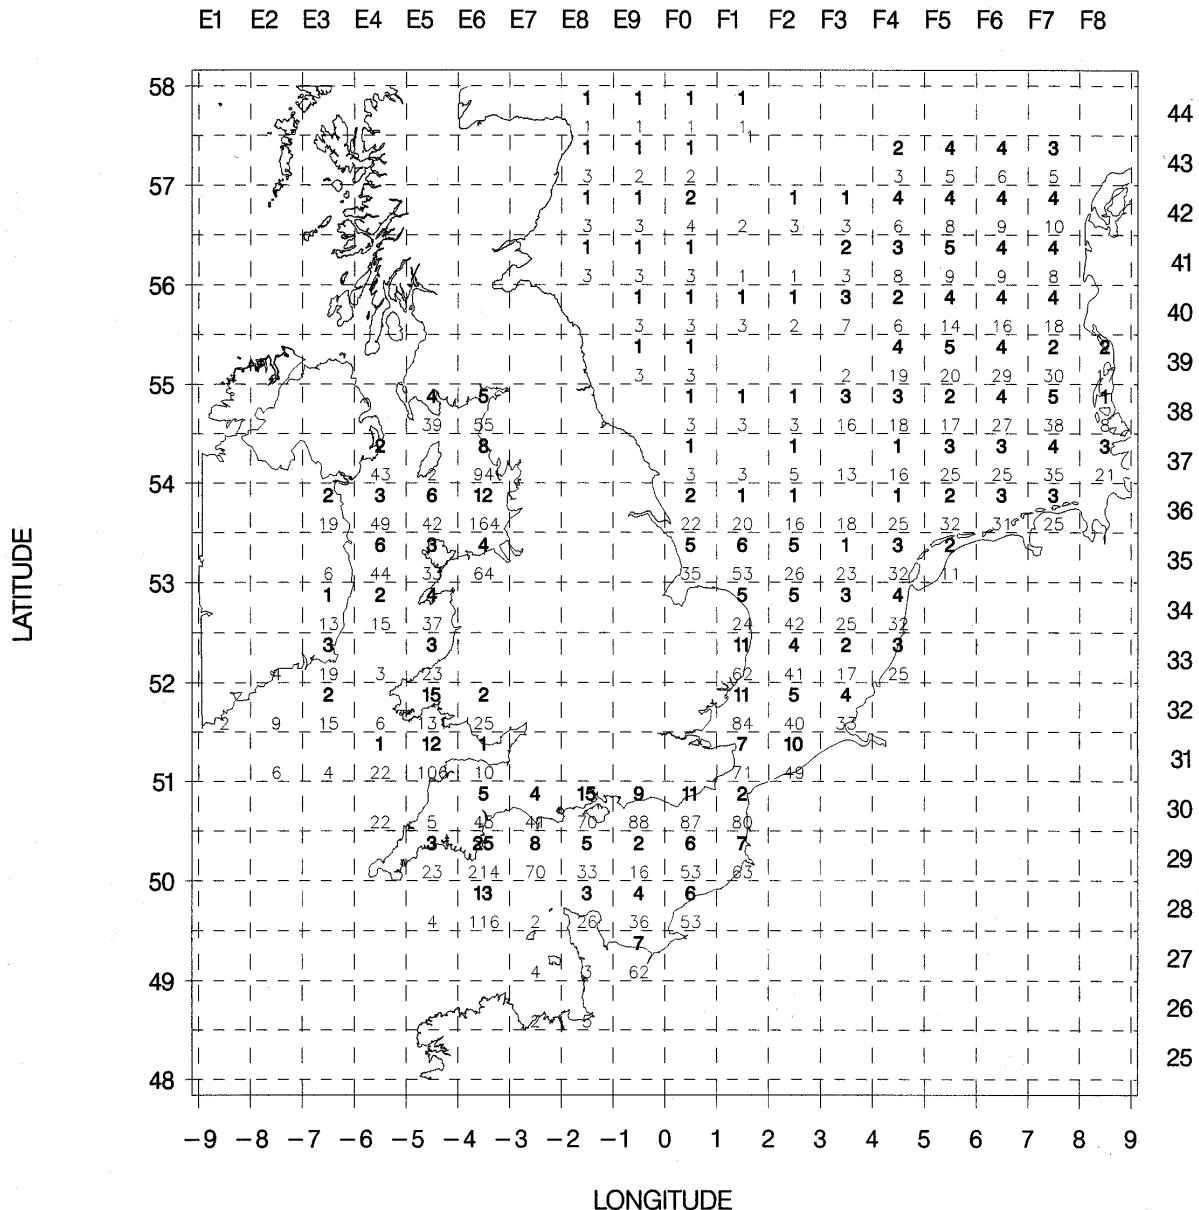

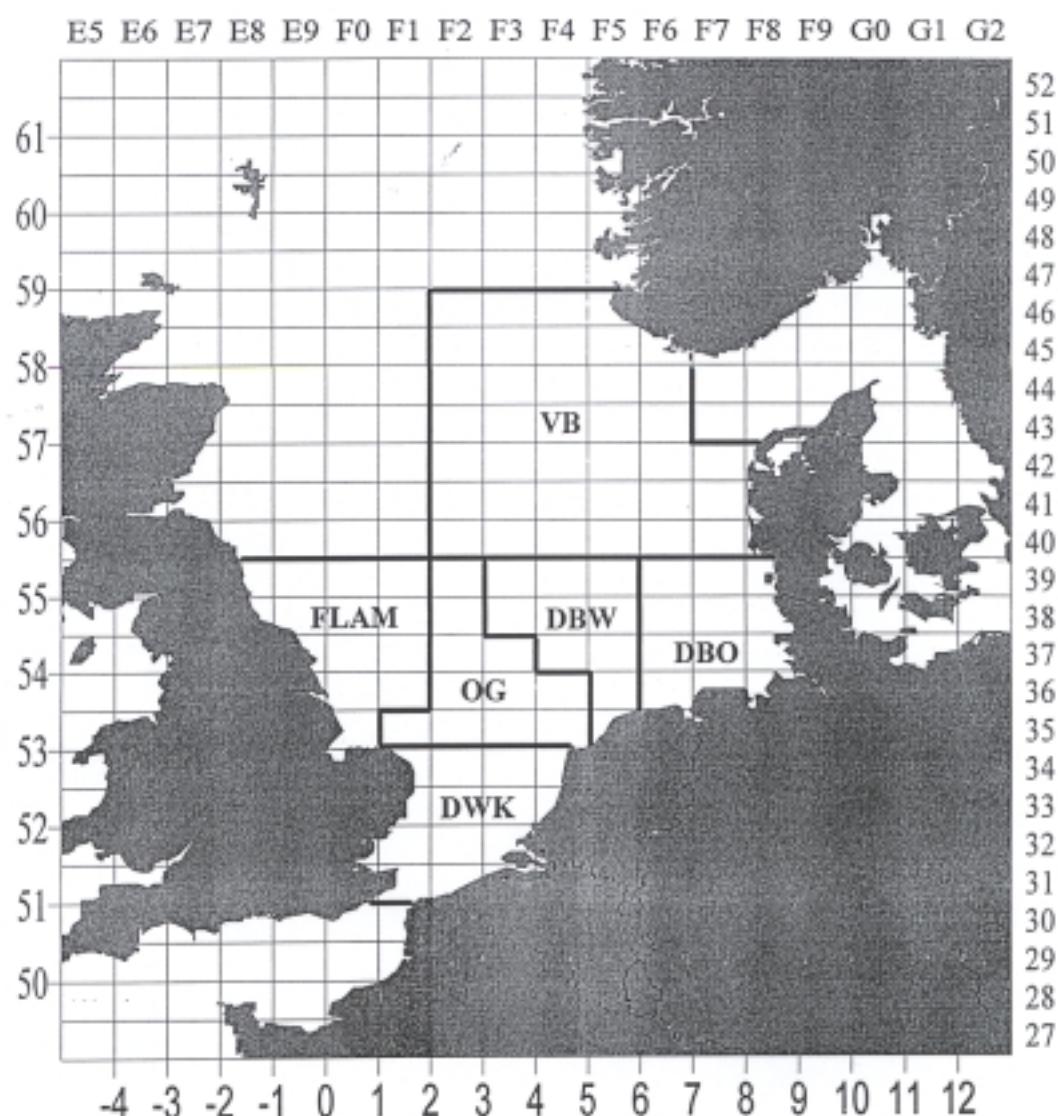

Fig. 2.2: Otolith sampling areas

Sub-area codes

Beam trawl survey sub-areas: 1995

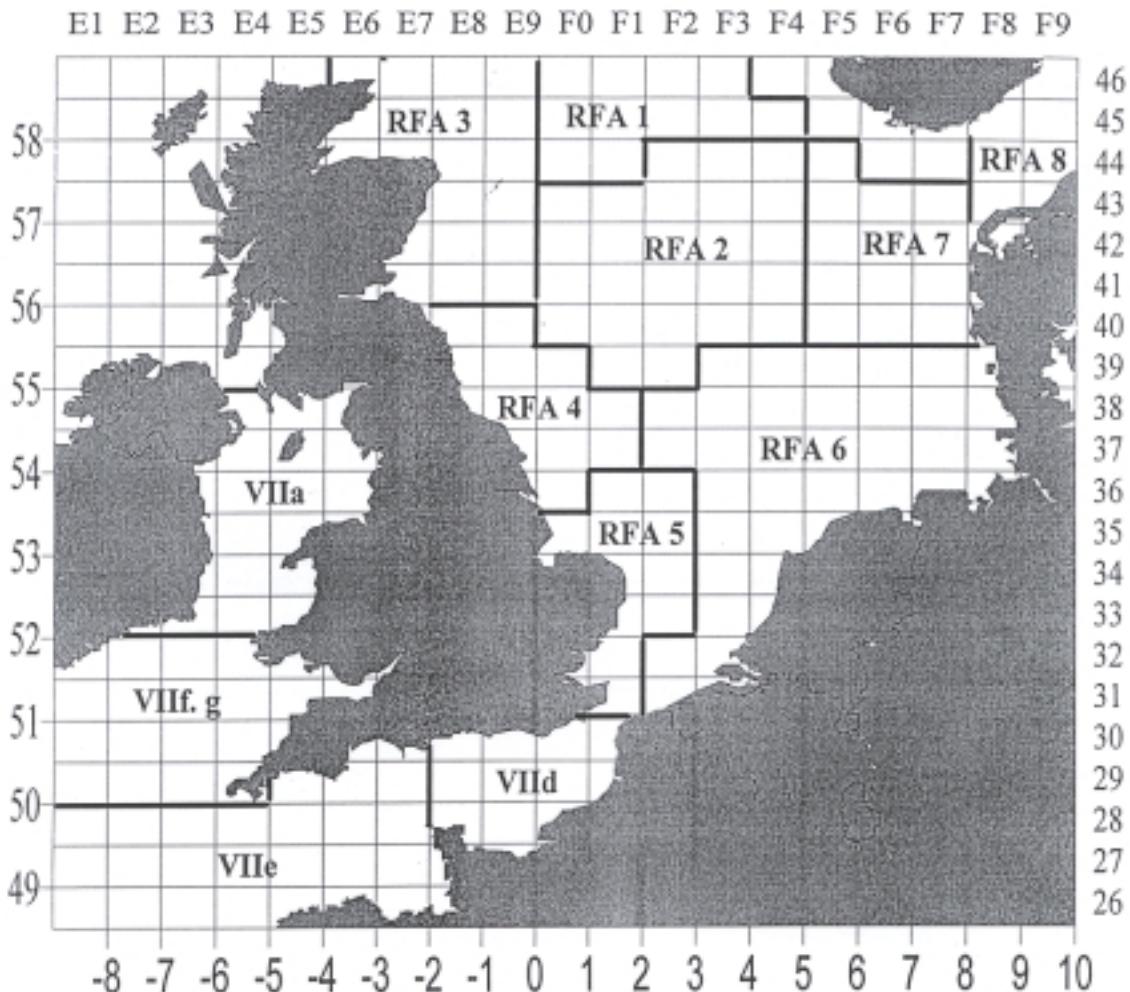

Fig. 2.3: Sub-areas for beam trawl surveys. Area classification is according to Roundfish areas for North Sea and Management areas (ICES Divisions) for other areas.
