2 INTRODUCTION

2.1 Terms of Reference

At the 79th Statutory Meeting of ICES in 1991 it was decided (C.Res.1991/2:7:13) that:

"The Arctic Fisheries Working Group (Chairman: Mr K. Sunnanå, Norway) will meet at ICES Headquarters from 25 August - 3 September 1992 to assess the status of and provide catch options for 1993 within safe biological limits for the stocks of cod, haddock, saithe, redfish and Greenland halibut in Sub-area I and II, taking into account of biological interactions between cod and capelin as far as possible."

3 NORTH-EAST ARCTIC COD (SUB-AREAS I AND II)

3.1 3.1 Status of the Fisheries

3.1.1 Landings prior to 1992 (Tables 3.1-3.4, Figure 3.1A)

The final reported landings of 1990 amounts to 187,000 t (Table 3.1), excluding 24,263 t of Norwegian coastal cod (Table 3.2). The provisional figures for 1991 are 257,882 t excluding 24,749 t Norwegian coastal cod. The agreed TAC on North-East Arctic cod was exceeded by 42,882 t, and the total quota including 40,000 t Norwegian coastal cod was exceeded by 27,631 t. This is about 6,500 t more than expected by the Working Group last year.

Table 3.3 shows that the increase in the landings has taken place mainly in Divisions IIa and IIb.

3.1.2 Expected landings in 1992

The final agreed TAC of North-East Arctic cod for 1992 was 356,000 t after it had been increased by 56,000 t during the year. According to the agreement between Norway and Russia, Norway is allowed to take an additional 40,000 t Norwegian coastal cod. From earlier experience and provisional reports it is expected that the total landings of cod will be about 406,000 t including about 30,000 t Norwegian coastal cod.

3.1.3 Effort and catch-per-unit-effort (Table 3.5)

The catch-per-unit-effort (CPUE) is derived by dividing the total catch by the total effort involved in taking the catch over the year, except for 1992, for which the data are from the first half of the year. For Norway and Russia, this effort will include effort directed towards other species.

From 1990 to 1991, there was a marked increase in the Russian CPUE in Division IIa, and a slight decrease in Sub-area I and Division IIb. There was also a strong increase in the Spanish CPUE in Division IIb. The Norwegian CPUE decreased in Sub-Area I and Division IIb, while it increased in Division IIa.

3.2 Data from Catches

3.2.1 Catch in numbers at age (Table 3.25)

Revised age compositions in the Norwegian landings together with final total landings were used to revise the numbers at age in the 1990 landings. For 1991, age compositions for all areas were available from Norway and Russia. From the UK, the age composition from Division IIa was available. Spain and Germany provided age compositions from Division IIb. Age compositions of the total landings were calculated separately in Sub-area I and Divisions IIa and IIb by using the age compositions provided and raising the landings from other countries (Denmark, Faroe Islands, France, Greenland, Portugal, the UK (I and IIb) and Germany (IIa)) by Norwegian trawl in Sub-area I, by UK trawl in Division IIa and by Spanish trawl in Division IIb.

The 1983 year class (age 8 in 1991) is still dominant in the catches, but its proportion of the total numbers has been reduced from 43% in 1990 to 29% in 1991. The ages 5-7 comprise 53% of the catch in numbers in 1991.

The catch in numbers at age for 1991 predicted last year assuming the fishing pattern to be the same in 1991 as in 1990 turned out to be rather close to the catch at age calculated this year, except that the catch of age 10 and older fish was substantially smaller than predicted last year.

3.2.2 Weight at age in the landings (Tables 3.6 and 3.20)

The mean weight at age in the catch (Table 3.20) is calculated as a weighted average of the weight in the catch from Norway and Russia (Table 3.6). The time series weights are used for the older age groups for the year classes prior to 1978. The weight at age in the Norwegian catches in 1990 has increased compared to last year, because there was an error in the length-weight relationship used last year. For 1992 the unweighted average of Norwegian and Russian weights in the first half of the year has been used.

From 1988 the calculated length-weight relationship in the Norwegian catches is based on individual length-weight measurements. This is also the case for the German length-weight relationship and the 1991 data from Germany and Norway show similar weights at age by area. These weights of fish of ages 6 and older show good correspondence with the Russian data. However, there is still a large difference for the younger fish. These differences may in part be due to the discrepancies in the age reading (Section 3.3.3).

3.3 Survey Results (Tables 3.7-3.12)

The surveys were updated by data from the last year. The age distribution in the Norwegian acoustic survey in the Barents Sea in February-March 1991 (Table 3.10) has been revised. For the Norwegian bottom trawl surveys (Tables 3.7 and 3.8) back-calculations from bobbins to rock-hopper gear have not yet been done for the 1981 and 1982 data.

3.3.1 Recruitment indices (Tables 3.13 and 3.14)

The recruitment indices were updated with the last year's data and are given in Table 3.13. The sizes of the recruiting year classes were estimated using the indices of the year classes at ages 0, 1, 2 and 3 from surveys and the program RCT3. No 0-group index for 1992 was available because the 0-group survey was not finished at the time of the Working Group meeting. The analysis was performed using the final VPA as input up to the 1986 year class.

The estimates of the 1987-1991 year classes (Table 3.14) were all higher than the estimates made by the Working Group last year. The difference was greatest for the 1989-1991 year classes, where new survey indices have been included.

3.3.2 Length and weight at age in the stock (Tables 3.15-3.19)

The length and weight-at-age data from the Russian survey in November-December 1990 (Tables 3.16 and

3.18) have been revised.

Stock weights used from 1985 to 1992 for ages 3 to 8 are averages of values derived from Norwegian surveys in January - February 1985 - 1992 and Russian surveys in November - December 1984 - 1991 to give representative values at 1 January (Table 3.19). For ages 9 and older, the weights from the time series are used, except for 1991 (age 9) and 1992 (ages 9 and 10), where the average of the survey weights are used, in the same way as for the younger year classes.

3.3.3 Discrepancies in age readings

It is evident from Tables 3.15-3.18 that for some years there is a discrepancy in length at age and weight at age between the Russian survey in October-December and the Norwegian survey in February-March which cannot be explained only by growth in the intermediate time. In addition to influencing the assessment of cod, this discrepancy will influence the assessment of capelin because the consumption of mature capelin by immature cod is assumed to be directly related to the biomass of the immature cod stock. Also, research on how the individual growth of cod depends on food supply and temperature, which is very important for making better prognosis on the development of the cod biomass, is greatly hampered by these discrepancies.

A working document on "Discrepancy of length at age and weight at age by cod" was presented. In this document cross-reading experiments on otoliths are analyzed. In general, there seems to be some correlation between the year-to-year variation in size at age in the survey and the variation between years in the discrepancy of the otolith reading.

The Russian age readings for the second half of 1990 were in error (too high) because of a new and inexperienced Russian reader. The Russian data (both survey data and data from catches) for that period will be revised. Some inconsistencies in weight-at-age data between the 1990 and 1991 Russian surveys may be explained by these errors. Also, the differences in size at age between the Norwegian and Russian surveys will become smaller.

3.3.4 Maturity ogives (Table 3.21)

As in 1991, only Russia provided a maturity ogive. For the last three years, there has been a trend towards earlier maturation.

3.4 Stock Assessment

3.4.1 Revised assessment using the revised data from 1991

Running last year's assessment with revised catch data and survey data, and iterating the tuning and the separable VPA to produce the same reference F_{5-10} , we get $F_{5-10} = 0.22$ which is lower than the $F_{5-10} = 0.28$ from last year's assessment. However, the F_{5-8} , which was 0.23 in last years assessment (tuning) and 0.25 (separable), drops only slightly, to 0.22. In the separable VPA an input $F_8 = 0.25$ and $S = 1.0$ was used, and the ratio of F_{old} to the average of the 4 younger ages in the tuning was set to 1.0.

3.4.2 Tuning the VPA to survey results (Tables 3.22-3.24)

It was decided to only use survey data as input to the tuning.

For age 9, the surveys give very low indices for most years, and a large part of the stock may be on the spawning grounds and hence outside the survey area for some of the surveys. Hence, it was decided to exclude this age group from the tuning. Also, it was decided not to exclude some year classes from the tuning for some of the surveys, as was done last year.

Earlier all the autumn surveys have been allocated to the year of the winter surveys. This was done because the tuning requires data for the last year for all indices used in the tuning. The Laurec-Shepherd tuning method compares the survey indices to the average population of the year but the surveys do not reflect the change in the average population caused by the fishing mortality in the year they are allocated to (i.e the year of the winter surveys). It is clear that the autumn surveys would compare best to the average population in the year they are conducted, and the winter surveys in the subsequent year are also reflecting the same stock level. In order to take account of the surveys conducted in the winter 1992, it was decided to allocate the autumn surveys to the year they are conducted, and to allocate the winter surveys to the year before they are conducted.

Running the tuning with the surveys in the calendar year, and iterating the separable VPA and the tuning in the way mentioned above, we get $F_{5-8} = 0.12$ and $F_{5-10} = 0.12$. The input to the tuning is given in table 3.22 and the results in Table 3.23. At this Working Group meeting, two other methods of tuning were available, the Extended Survivors Analysis (XSA) (Shepherd, 1992) and the ADAPT framework (Gavaris, 1988). Both were run on the same data and gave $F_{5-10} = 0.21$ and $F_{5-8} = 0.20$ (ADAPT) and $F_{5-8} = 0.20$ (XSA). XSA had to be run including only the ages 3-8, for which there are

tuning data. ADAPT was run with F at ages older than 8 equal to F at age 8.

The Working Group has little confidence in the F level obtained from the iteration of the Laurec-Shepherd tuning and the separable VPA. Because the XSA and the ADAPT gave the same F level, it was decided to accept this as the 1991 fishing level. The separable VPA and the ADAPT were iterated to produce the same reference F, using S = 1.0. The final F_8 was 0.24. The separable VPA gave F's on younger ages lower than the ADAPT values while the F's on ages 7 and 8 were slightly higher. Given that the two techniques which yielded the accepted F_{5-8} are relatively new to this Working Group, it was decided to use the separable VPA with $F_{5-8} = 0.20$. The resulting fishing pattern is given in Table 3.24.

3.4.3 Final VPA and present state of the stock (Tables 3.25-3.30)

It was decided not to accept the population size of the 1987 and 1988 year class from the separable VPA. These values were (at age 3) 184 and 725 million, respectively, while the RCT3 gave 139 and 226 million for these two year classes. The final VPA was run using the Fs from the separable VPA as input, except for age 3 and 4, where these mortalities were adjusted to give the same population at age 3 as obtained from the RCT3 program. The fishing mortalities and stock numbers and biomasses are given in Tables 3.25-3.29. A summary of landings, fishing mortality and biomass since 1962 is given in Table 3.30.

3.5 Prediction of Catch and Stock Biomass

3.5.1 Input variables to the prediction (Table 3.31)

The stock number at age is taken from the final VPA (Table 3.27) and the recruitment of the 1989 year class from Table 3.14. The fishing pattern is taken from the separable VPA (Table 3.24). The maturity ogive is taken as the average of the recent 3 years (1990-1992) in Table 3.21 and is used for 1993 onwards.

The recruitment in the prediction is taken from the RCT3 analysis for the 1990 and 1991 year classes (Table 3.14). The recruitment of the 1992 and later year classes is set to the recent average (VPA mean = 5.67 = 290 million). For the management option table the weight at age in the stock and the catches is set to the average of the recent 3 years (1990-1992) for 1993 onwards. (Tables 3.19 and 3.20).

For the medium term prediction (1994-1997) 3 different scenarios were chosen to give an indication of the uncertainty of the predictions. Two biological reference points, F_{low} and F_{med} were given in each scenario. The

scenarios are only considering different weight at age, i.e. different growth, as the source of uncertainty. The scenarios are the following: Weight at age equal to the average in the years 1983-1986, i.e. high growth, weight at age equal to the average in the years 1983-1992, i.e. average growth, and weight at age are equal to the average in the years 1987-1990, i.e. low growth. The scenario weights are taken from Table 3.19 and 3.20. The weights given in Table 3.31 are used for 1992 and 1993 and the scenario weights are used from 1994 onwards.

3.5.2 Biological reference points

The yield per recruit analysis using the same fishing pattern and stock parameters as in the management option table resulted in estimates of $F_{0.1} = 0.14$ and $F_{\max} = 0.25$. Jakobsen (1992) gives the values of $F_{\text{low}} = 0.32$, $F_{\text{med}} = 0.46$ and $F_{\text{high}} = 0.78$ for North-East Arctic Cod. The present exploitation level is $F_{92} = 0.31$. The exploitation level of $F = 0.19$ estimated for 1991 is influenced by the abnormal exploitation pattern in that year and is likely to be an underestimate.

3.5.3 Projections of catch and biomass (Tables 3.32-3.33)

The management options are given in Table 3.32 for the F-values $F_{0.1}$, F_{91} , F_{\max} , F_{low} , F_{92} , F_{med} and F_{high} . In Figure 3.1D the catch level in 1993 and spawning stock biomass level in 1994 are plotted against the fishing mortality, F , in 1992.

In Table 3.33, the results of the three growth scenarios for the medium-term prediction are given, for the biological reference points F_{low} and F_{med} . It should be noted that these scenarios are not assessments, but calculations. The aim of these calculations is to demonstrate the uncertainty introduced in long term predictions because of the large change in growth experienced in this stock. The catches in the table must therefore not be taken as options for long term strategies.

3.5.4 Comments to the stock situation

The stock situation has improved much quicker than expected after the current severe management strategy was introduced in 1989. This rapid development is due mainly to good growth. Early maturity has given an additional growth in the spawning stock. The Working Group feels that the severe restrictions on the fishery, although in retrospect perhaps more severe than intended, have been very beneficial to the stock. In future management the main objective should be to maintain the spawning stock biomass at a high level to avoid further long periods of very poor recruitment.

3.6 SHOT Forecast for Coastal Cod (Table 3.34)

The Working Group had no new available information concerning coastal cod. As in last year, a SHOT forecast was made using the estimated catch of Norwegian coastal cod in 1991. However, it is the opinion of the Working Group that only a combined assessment should be made to avoid future overshooting of the North-East Arctic cod TAC. Norwegian and Russian scientists will consider arranging a study group to look more closely into the problems with carrying out a combined assessment.

The SHOT forecast was made according to the method described by Shepherd (1991). The input to the forecast was the catches in '000 tonnes (Table 3.2) The natural mortality was set to $M = 0.2$ and the growth rate, as estimated last year, to $G = 0.42$. The yield per biomass rate was calculated using input F values to adjust the estimated landings to be equal to the actual landings. No recruitment indices were available and the series were set to 1.0. The result is given in Table 3.34.

Under these assumptions the decrease in yield from about 40,000 t to about 30,000 t in the years 1984 to 1987 is caused by a reduction in F. The observed low growth in the North-East Arctic cod is also reflected in the low production estimates of 1988 and 1989. The low F level in 1989, due to a stop in the fishery, has been followed by an increase to the present level of $F = 0.21$. Continued fishing at this level will give a catch of 27,000 t in 1992 and 30,000 t in 1993.

4 NORTH-EAST ARCTIC HADDOCK (SUB-AREAS I AND II)

4.1 Status of the Fisheries

4.1.1 Landings prior to 1992 (Tables 4.1, 4.2 and 4.3, Figure 4.1A)

The final landings figure for 1990 was 25,816 t which is close to the figure used in last year's assessment. This figure is 816 t more than the agreed TAC. The preliminary landings figure for 1991 is 33,214 t which is 5,214 t more than the agreed TAC and 4,714 t more than expected in last year's meeting. The increase in catch from 1990 to 1991 has taken place both in Sub-area I and Division IIa in almost equal quantities.

4.1.2 Expected landings in 1992

The agreed TAC of North-east Arctic haddock for 1992 is 63,000 t after it had been increased by 8,000 t during the year. Based on reports for the first half of the year, the expected landings in 1992 will be 54,000 t, which is 9,000 t below the agreed TAC.

4.1.3 Effort and catch per unit effort.

No new effort data were available at this meeting because the haddock caught by trawl in 1991 was only by-catch. The data on catch per unit effort are not used in the assessment and the table containing effort data is removed from this year's report.

4.2 Data from Catches

4.2.1 Catch in numbers at age (Table 4.21)

Revised age compositions in the Norwegian landings together with final total landings were used to revise the numbers at age in the 1990 landings.

For 1991, age compositions of the catches were available from Norway in all areas, from Russia in Sub-area I and Division IIa, from Germany in Division IIb and from UK (England and Wales) in Division IIa. The catches of other countries were distributed on ages using an average Norwegian and Russian age composition in area I, the UK (England and Wales) age composition in Division IIa and the German age composition in Division IIb.

As the catch in 1991 is 4,714 t more than expected in last year's meeting, the catch in numbers are also significantly different from the estimate made at that meeting. However, the relative distribution of numbers at age is also very different from the one predicted last year using the fishing pattern from the tuning. The catches of 3 and 4 year olds are larger than predicted. So is the catch of age 7 (1984 year class) whereas the catch of age 8 (1983 year class) is lower.

4.2.2 Weight at age in the landings (Tables 4.4 and 4.16)

There seems to be a reasonable correspondence between the Norwegian and Russian weights at age in the catches in recent years (Table 4.4). In general, for ages 3 and 4 the Norwegian weights are higher and for the older individuals the Russian weights are slightly higher. The mean weight at age in the catch (Table 4.16) is calculated as a weighted average of the weight in the catch from Norway and Russia. For 1992 the unweighted average of Norwegian and Russian weights in the first half of the year have been used.

4.3 Survey Results (Tables 4.5 - 4.10)

Results from the Barents Sea bottom trawl survey in the winter 1992, the Svalbard bottom trawl survey in the autumn 1991 (new table this year), the Barents Sea acoustic survey in winter 1992, and the Svalbard - Barents Sea acoustic survey in the autumn 1991 were available from Norway. From Russia the data from the trawl survey and the acoustic survey in the Barents Sea

and adjacent waters in late autumn 1991 were available.

4.3.1 Recruitment indices (Tables 4.11 and 4.12)

The recruitment indices were updated and the indices are given in Table 4.11. The analysis of recruitment is carried out using the final VPA as input up to 1988 year class. Because of the tendency of the C-type regression to overestimate the recruitment for haddock it was decided to use a P-type regression and not to shrink the estimates towards the mean.

4.3.2 Length and weight at age in the stock (Tables 4.13 - 4.15)

Weight at age is available from Russian autumn survey from 1984 representing weight at age from 1 January 1985. These weights seem to correspond fairly well with the old time series and are therefore used as weight at age in 1985 and 1986 for ages up to 7 year. From 1987 the weighted average of Norwegian weight at age in the winter survey and Russian weight at age on the same year class in the autumn survey the year before are used up to and including age 7.

Few fishes of older ages have been found in the surveys in the 1980s. The first year class showing up as older fish is the 1982 year class and it was decided to allow this year class to update the weight and length at age for the older fish in the Tables 4.13 and 4.14 showing the length and weight at age in the Norwegian bottom trawl survey in early winter and the Russian trawl acoustic survey in late autumn. The weight at age in the stock is calculated as the unweighted average of the Norwegian and Russian weights from the surveys up to the 1982 year class. For the older fish the old time series is used (Table 4.15)

4.3.3 Maturity ogives (Table 4.17)

Maturity ogives were available from Russia for 1991 and 1992 and is given in Table 4.17.

4.4 Stock Assessment

4.4.1 Tuning the VPA to survey results (Tables 4.18 - 4.20)

The tuning module in the VPA using the Laurec-Shepherd method was run using the updated 1991 catch at age data. The same procedure as last year was followed, iterating the tuning module and the separable module to give corresponding $F_{4.7}$. The terminal S-value in the separable was set to 0.7. The ratio of oldest F to the average of the 4 preceding ages in the tuning was also set to 0.7 and the input Fs to be given in the tuning were taken to be the Fs from the separable VPA. An $F_{4.7} = 0.20$ was found for 1990 and this is higher than the $F_{4.7}$

= 0.10 that was found in last year's assessment.

In last year's assessment the predicted catches in 1991 were included in the VPA in order to take account of the survey results obtained in 1991. The catch at age reported to the Working Group this year differ considerably from the ones predicted last year. Less fish are caught of the 1983 year class and more are caught of the 1984 year class. Also a considerably higher catch of 3 and 4 year olds was reported. This causes a higher F_{4+} to be estimated and a corresponding lower stock size. Doubts about the quality of the predicted catch at age data together with possible problems arising from using the estimated catches from a tuned VPA into a similar VPA, made the Working Group decide not to run the VPA including the year 1992.

The surveys are allocated to years in the same way and for the same reason as for cod, see Section 3.4.1. The tuning data are given in Table 4.18 for the ages 3 to 7. The year of the earliest survey index is 1980 for the Norwegian bottom trawl survey conducted in February 1981. The different surveys are the Norwegian bottom trawl survey in February (Fleet 1), the Norwegian acoustic survey at the same time (Fleet 2), the Russian bottom trawl survey in October - December (Fleet 3) and the Russian acoustic survey at the same time (Fleet 4).

The Laurec-Shepherd tuning was iterated with the separable VPA using $S = 0.7$ in the separable VPA, $r = 0.7$ in the tuning and the input F's to the tuning taken from the separable VPA. It resulted in $F_{4+} = 0.34$, which is considerably higher than the assessment of last year and the first run done on the revised catch data. It shows that introducing the survey indices of autumn 1991 and winter 1992 into the tuning give a somewhat lower abundance.

At this Working Group meeting, two other methods of tuning were available, the Extended Survivors Analysis (Shepherd, 1992) and the ADAPT framework (Gavaris, 1988). Both were run on the same data and gave $F_{4+} = 0.32$ from the XSA and $F_{4+} = 0.28$ from the ADAPT. Both these methods confirm the general level of F in 1991. Both the XSA and ADAPT allow the surveys to be allocated to the time of the year they were conducted, and runs performed on the last years assessment allocating the surveys as close to their time of performance as possible gave F_{4+} close to 0.3 for both methods. The XSA had to be run only including the ages for which there are survey indices. The theory behind XSA and ADAPT is new to the Working Group and since there is no major conflict between the F-level from any of the methods, it was decided to carry out the assessment this year as usual, using the Laurec-Shepherd tuning iterated with the separable VPA.

4.4.2 Final VPA and state of the stock (Tables 4.21 - 4.26)

The analysis of the residuals from the separable VPA indicate that the fishing pattern is fairly stable, except from the oldest ages in the later years. It was therefore decided to use the separable VPA as the final VPA. The final VPA was then run using the terminal F's from the separable VPA as input to the IFAP files, and then running a standard VPA back to 1962. The results are given in Tables 4.22 to 4.26.

The F's on the youngest ages are somewhat higher in the tuning (Table 4.19) than in the final VPA (Table 4.22). From the recruitment analysis (Table 4.12) it is seen that the 1988 year class (34 million individuals) is estimated as below average, but it is found to be abundant in the catches in 1991. It is clear from the data (Table 4.11) that all surveys show a year class strength at age 3 above average. However, the time series having the highest weight in the regression is for age 2 and fails to pick up this year class. The time series for age 3, estimates the 1988 year class to 76 million individuals. The figures of 3 year olds in the final VPA is left unchanged, but may be an overestimate of the 1988 year class as 3 year olds.

A summary of landings, fishing mortality, recruitment and biomass since 1962 is given in Table 4.26.

4.5 Prediction of Catch and Biomass

4.5.1 Input variables to the prediction (Table 4.27)

The recruitment in the prediction is taken from Table 4.12, showing that the 1989 and 1991 year classes are abundant and the 1990 is a strong year class. The somewhat high abundance in the VPA of the 1988 year class may be compensated by the following year classes due to the tendency of the P-type regression to underestimate strong recruitment. The recruitments of the 1992 and later year classes are taken as the recent average of 40 million individuals (log value of 3.65 as VPA mean in Table 4.12).

The stock size at age in 1992 is taken from the final VPA (Table 4.23) and the recruitment of the 1989 year class from Table 4.12. The fishing pattern to be used in the predictions is the separable fishing pattern (Table 4.20). The F pattern is calculated so that the F factors are equal to the average F_{4+} .

The maturity is taken as the average of the recent 3 years in Table 4.17. For the management option table the weight at age in the catches and in the stock is taken as the value given for 1992 and as the average of the recent 3 years in Tables 4.15 and 4.16, i.e. 1990 - 1992 for 1993 and 1994.

For the medium term prediction, 3 different scenarios were chosen to give an indication of the uncertainty of the predictions. Two biological reference points, $F_{0.1}$ and F_{med} , were given in each scenario. The scenarios are only considering different weight at age, i.e. different growth, as the source of uncertainty. The scenarios are the following: Weight at age equal to the average in the years 1983 - 1986, i.e. high growth, weight at age equal to the average in the years 1983 - 1992, i.e. average growth, and weight at age equal to the average in the years 1987 - 1990, i.e. low growth. The scenario weights are taken from Tables 4.15 and 4.16 for the stock weights and catch weights respectively. The weights given in Table 4.27 are used for 1992 and 1993 and the scenario weights are used from 1994.

4.5.2 Biological reference points

The yield-per-recruit-analysis was performed with the fishing pattern used in the prediction and the 1992 weight at age in the stock and in the catches. This resulted in $F_{0.1} = 0.14$ and $F_{max} = 1.23$ (Figure 4.1C) Jakobsen (1992) gives the values of $F_{low} = 0.02$, $F_{med} = 0.35$ and $F_{high} = 1.11$ for the North-East Arctic haddock. The present exploitation level is $F_{92} = 0.35$, which is equal to F_{med} .

4.5.3 Projection of catch and biomass (Tables 4.28 and 4.29)

The management options table is given in Table 4.28, and the F -values of $F_{0.1}$, F_{90} , F_{91} and $F_{med} = F_{92}$ are shown. Figure 4.1D shows the plot of the catch and spawning stock biomass levels in 1993 by choice of fishing mortality, F .

The medium term scenarios are given in Table 4.29 and show that the spawning stock will increase in all the scenarios. The total biomass will also increase, but it will decrease somewhat at the end of the period. For one scenario, low growth and F_{med} fishing, the stock will be close to the present level in 1997. It should be noted that these scenarios are not assessments, but calculations. The aim of these calculations are to demonstrate the uncertainty introduced in long term predictions because of the large change in growth experienced in this stock. The catches in the table must therefore not be taken as options for long term strategies.

4.5.4 Comments on the stock situation and the assessment.

The recruitment of the year classes 1988 to 1991 does not seem to give as large a contribution to the stock as the year classes 1982 to 1984. Also, the recruitment is not yet showing up in the fishery and care should be taken not to increase the exploitation level above the present level.

5 NORTH-EAST ARCTIC SAITHE (SUB-AREAS I AND II)

5.1 Status of the Fishery

5.1.1 Landings prior to 1992 (Tables 5.1 and 5.2, Figure 5.1A)

Revised landings as reported to ICES for 1990 were 95,393 t, a decrease of 26,917 t from 1989 (Table 5.1). Provisional reports of landings in 1991 give a total of 109,221 t compared to 100,000 t expected by last year's Working Group. The increase is due to the purse seine fishery where landings went up to nearly the same level as from the trawlers (Table 5.2).

5.1.2 Expected landings in 1992

Norwegian authorities have introduced quota regulations for other countries and for purse seine and trawl in the Norwegian fisheries in order to limit the total landings in 1992 to the *status quo* F level of 115,000 t. Landings to date in 1992 do not give any basis for revising this figure.

5.1.3 Effort and catch-per-unit effort (Tables 5.3-5.5)

Table 5.3 shows the number of vessels of different size categories that have taken part in the purse seine fishery for saithe since 1977, with corresponding catch and catch per vessel. On the basis of these data, indices of total purse seine effort have been calculated and are given in Table 5.5. The unit of effort is number of vessels of 20-24.9 m. This category currently accounts for about half of the purse seine landings and comprises most of the typical purse seiners, i.e., vessels having purse seining for saithe as main form of fishing. An increase in purse seine effort of 9% from 1990 to 1991 is indicated.

Table 5.4 gives catch, effort, and catch per unit effort for Norwegian trawlers since 1976, including only hauls where the effort almost certainly has been directed towards saithe, i.e., hauls with more than 50% saithe on trips with more than 50% saithe. Indices of total Norwegian trawl effort are given in Table 5.5 and show a decrease from 1990 to 1991 of 13%.

Combined effort has also been calculated (Table 5.5). Catches from the two gear categories have on average been at the same level (Table 5.2) and the indices have been given equal weight. Using 1977-1990 as a reference period, multiplying the trawl indices by 2.75 raises them to the same average level as the purse seine indices. The indices are then added to give the combined index. There is a decrease of 5% in the combined index from 1990 to 1991.

5.2 Catch in Numbers at Age (Table 5.10)

Age compositions of Norwegian landings in 1990 were revised. There were substantial changes, especially on age groups 2-4. The main reason for the changes is that some Norwegian age samples failed to show up in the data output prepared for last year's meeting. Data for 1991 were available from Germany and Norway, accounting for 98% of the landings. Landings by other countries were assumed to have the same age composition as that of Germany.

5.3 Weight-at-Age (Table 5.11)

A constant set of weight-at-age data is used for all years in the period 1962-1979. For subsequent years, annual estimates of weight-at-age in the catches are used. Data for 1990 were revised and for most age groups the revision gave an increase, at age 2 by as much as 46%. The main reason is the data problem mentioned in Section 5.2. New data were available for 1991. The weight-at-age in the stock is assumed to be equal to the weight-at-age in the catch.

5.4 Age at Maturity

No maturity ogive is available for this stock. As in the previous assessments, knife-edge maturity at age 6 has been assumed.

5.5 Survey Results (Table 5.6)

An acoustic survey for saithe in October-November was started in 1985. Indices of abundance of immature saithe are obtained (Table 5.6) and are used in the VPA tuning. The 1988 year class was abundant at age 2 in the 1990 survey, but the Working Group felt last year that more evidence was needed on the year-class strength. The 1988 year class was accordingly assumed to be average. The 1991 survey, however, confirmed that the 1988 year class is substantially stronger than the previous ones in the series. This is also evident from the catch-at-age data (Table 5.10). The 1991 survey indicates that the 1989 year class is also relatively abundant.

5.6 Recruitment

The index for the 1988 year class from the 0-group (post-larvae) survey is very low compared to the indices for the 1985-1987 year classes. The abundance indices for the year classes 1985-1992 are: 828, 545, 280, 165, 242, 58, 637, 443. Since the 1988 year class evidently is stronger than the proceeding ones, the prospect of being able to estimate recruitment from this survey is poor even if some of the discrepancy can be explained by predation by seals during the invasion of seals in coastal areas in 1987 and 1988. Considering the good coverage of the survey, it is possible that the year class strength is

still not established at that time (around May).

5.7 Fishing Mortalities and VPA (Tables 5.7-5.16, Figures 5.1A and 5.1B)

In the assessment last year, catch and effort data for trawl and purse seine were combined in the VPA tuning. One reason for this was that tuning with the separate fleets gave results that were inconsistent with earlier assessment. Trial VPA tuning runs this year revealed that the inconsistency was caused by the catch-at-age data problem mentioned in Section 5.2. There is little difference in tuning results between separate and combined fleets for running VPA up to both 1990 and 1991. In spite of the substantial change in catch-at-age data, repetition of last year's assessment resulted in approximately the same level of fishing mortality. Although the tuning diagnostics for combined fleets are still somewhat better than for separate fleets, the Working Group decided on the basis of the comments made by ACFM to use separate fleets in the tuning. The two fleets are used together with the Norwegian acoustic survey (Table 5.7) and the results of the tuning are given in Table 5.8. F_{3-6} for 1991 was estimated to be 0.40.

The fishing mortality levels from the tuning were carried forward to the separable VPA (Table 5.9). The resulting fishing mortalities were used as input to the conventional VPA and the results are given in Tables 5.12-5.15 and Figures 5.1A and 5.1B. The fishing mortality in the most recent years is markedly higher than in last year's assessment and biomass estimates correspondingly lower. Thus, the trend in spawning stock biomass after 1988 is no longer increasing.

Uncertainty about the size of the 1987 year class was expressed by the Working Group last year. After the revision of the catch-at-age data, this year class is now clearly established as a poor one. The 1988 year class, however, appears to be one of the strongest on record. A summary of landings, fishing mortality recruitment and biomass since 1962 is given in Table 5.16.

Runs were also made with ADAPT and the Extended Survivors Analysis. The former gave a lower fishing mortality ($F_{3-6} = 0.29$) than the Laurec-Shepherd tuning, whereas the XSA gave a slightly higher value ($F_{3-6} = 0.50$). Excluding age 8 in the tuning gave lower values for both methods, 0.25 for ADAPT and 0.42 for XSA, and indicates that these methods, like Laurec-Shepherd, are vulnerable to sample errors on the older age groups.

5.8 Prediction of Catch and Biomass

5.8.1 Input variables to the predictions (Table 5.17)

Input variables to the predictions are given in Table

5.17. The separable exploitation pattern and mean weights of 1990 and 1991 are used.

The estimates of recruiting year classes up to the 1988 year class, from the VPA, was accepted. Population numbers for these year classes in 1992 were used as inputs to the predictions. For the 1989 year class, evidence on the abundance is conflicting. The catches indicate a year class of below average strength, whereas the survey abundance at age 2 was nearly as high as for the 1988 year class. The size of the 1989 year class represents the largest uncertainty in the short-term prediction and three options are therefore presented, assuming the 1989 year class abundance to be low, medium and high, respectively. The low level (182 millions at age 1) is taken from the VPA, i.e., the one based on the catch at age 2 and the F at age 2 from terminal populations in the separable VPA. The high level (404 millions at age 1) is taken from tuning with age 2 in the survey included. The medium level (294 millions at age 1) is the mean of these two. For more recent year classes, 200 millions at age 1 was used, corresponding approximately to the average recruitment in the 1980s.

5.8.2 Biological reference points

Yield and SSB per recruit was based on the parameters in Table 5.17. The calculations gave $F_{0.1} = 0.18$ and $F_{\max} = 0.32$ (Figure 5.1C). The values of F_{low} , F_{med} and F_{high} were not recalculated and the values estimated last year as 0.17, 0.31 and 0.46, respectively, are used.

5.8.3 Results of the prediction (Tables 5.18-5.20)

Tables 5.18, 5.19 and 5.20 represent options 1, 2 and 3 respectively, for the size of the 1989 year class. Fishing mortality ($F_{3.6}$) in 1991 for landings of 115,000 t will be in the range of 0.29-0.36, depending on the strength of the 1989 year class. Landings in 1993 at F_{med} will be in the range of 107,000-144,000 t, for the *status quo* F (1991) level in the range of 132,000-177,000 t and for the *status quo* F (1992) level in the range of 121,000-137,000 t. Because of the strong 1988 year class, spawning stock biomass estimates increase in 1994 for all options and will reach about 200,000 t, more than twice the 1992 level, assuming catches near recent levels in 1993.

5.9 Comments on the Assessment

The data from the commercial fleets have limitations and considerable year to year changes in the assessment are also likely to occur in the future. The design of the acoustic survey has been gradually established during its six years' history and the survey may become a stabilizing factor in the VPA tuning in the future. The survey gave strong signals about the 1988 year class which have

been confirmed in the fisheries. If the survey proves to be a good predictor of year class strength at age 2, it will reduce a lot of the uncertainty in the predictions.

6 REDFISH IN SUB-AREAS I AND II

6.1 Status of the Fisheries

6.1.1 Landings prior to 1992 (Tables 6.1-6.6, Figure 6.3A)

Nominal catches by country for Sub-areas I and II combined are presented in Table 6.1. The nominal catches by country for Sub-area I and Divisions IIa and IIb separately are shown in Tables 6.2-6.4. The total catch in 1991 was 61,526 t, nearly the same amount as in the year before.

The landings of 2,820 t from Sub-area I in 1991 were at the average level of the 1980s. Landings in Division IIa declined from 100,163 t in 1983 to 27,729 t in 1987, but show an increase to 47,389 t in 1991. This is accounted for by an increase in the Norwegian landings. Landings in Division IIb increased considerably in 1990 due to the German (former GDR), the Norwegian and the Russian fisheries. Although the Norwegian fishery continued to increase in 1991, the total landings of 11,317 t were less than the year before due to a decrease in the German and Russian fisheries.

The national landings statistics of redfish for Russia, Germany, Norway, and Spain are split into species by the respective national laboratories. For other countries, the Working Group has split the landings into *Sebastes mentella* and *Sebastes marinus* based on reports from their different fleets to the Norwegian fisheries authorities. The total landings of *S. mentella* declined progressively from 115,383 t in 1982 to only 10,518 t in 1987, but since showed an increase to 39,983 t in 1991. This is 7,983 t more than expected from last year's prediction, and is caused by a 150% increase in the Norwegian landings of this species since 1990. Landings of *S. marinus* in 1991 were 21,543 t, a decrease compared to 1990, and 10,457 t less than expected in the last year's prediction, and this may be attributed to revised Norwegian catch statistics.

The redfish population in Sub-area IV (North Sea) is believed to belong to the North-East Arctic stock. The landings from Sub-area IV have been about 1,000-2,000 t per year (Table 6.6). Historically these landings have been *S. marinus*, but in the most recent years Norwegian trawlers have also caught *S. mentella* along the northern slopes of this sub-area. The catches are not included in the assessment.

6.1.2 Expected landings in 1992

On the basis of reports of landings from the first seven months of the year, landings expected for the whole 1992 are estimated to decrease compared to 1991 for both species, i.e., 20,000 t and 12,000 t for *S. mentella* and *S. marinus*, respectively.

Although higher quotas of cod and haddock have reduced the pressure upon the redfish stocks, CPUE in the Russian fishery for *S. mentella* is decreasing. CPUE from the Norwegian trawl fishery, although variable, indicates a decreasing trend. This could be an indication of stock reduction. It is expected that both the Russian and the Norwegian landings will be about 10,000 t less than in 1991. Provided the expectations for 1992 hold, then the landings of *S. mentella* will be close to the recommended precautionary TAC of 22,000 t.

Regarding *S. marinus*, Norwegian fishermen are worried about the stock and say it must be declining. Provided the expectations for 1992 hold, then the landings of *S. marinus* will be 13,000 t below the recommended precautionary catch of 25,000 t.

6.1.3 Effort and catch per unit effort (Tables 6.7 and 6.8)

Catch-per-hour-trawling data for the *S. mentella* fishery were available for the Russian PST vessels. There is an increase from 1987 to 1990, while a 40% decrease is observed from 1990 to 1992. Estimates of total effort are based on Russian PST units raised to total international catch, showing an increasing trend for 1987 to 1991, but a decline in 1992.

Data for *S. marinus* were available for Norwegian fresh fish trawlers from 1981 (Table 6.8) from which the total international effort was estimated. This is a new series using GLIM analysis on data from each month and the statistical areas 03, 04, 05, 06 and 07 along the Norwegian coast. Difficulties related to the splitting of the redfish species in the catches should lead us to be careful when using this series, and the observed increasing trend may not be correct. This will be further investigated.

6.2 Catch in Numbers at Age (Tables 6.16 and 6.25)

Data for 1989 and 1990 were revised. Data for 1991 for *S. mentella* were available from Russia and Norway, corresponding to 35% and 63% of the total landings, respectively. The Norwegian age readings were based on otoliths and the catch-at-age from Norway were clearly different from the Russian. The Working Group decided last year to wait until at least five subsequent years with otolith readings are available before it should be tried to implement it in an assessment. The Norwegian catch-at-

length data were therefore converted to ages using the Russian age-length key from Division IIa. The landings from other countries were distributed on age according to the combined age distribution from these two countries.

For *S. marinus*, age composition data for 1991 (based on otoliths) were only provided by Norway, accounting for 88% of the total landings. From the German fishery, accounting for nearly 5% of the total, catch-at-length data were available, and these were converted to age by using a Norwegian age-length key for trawl from the area and time the German fishery was conducted. The landings from other countries were distributed on age according to the combined age distribution from Germany and Norway.

6.3 Weight at Age (Table 6.17)

Catch weight-at-age data were available from Russia for *S. mentella* for the ages 5-18 in 1991 and from Norway for the ages 10-24 based on otoliths. Mean length-at-age of the Norwegian landings coming out from using the Russian age-length key (scales) were converted to weight-at-age using the relationship W (kilogram) = $0.0000314 \times L^{2.75}$ (cm), which is based on Norwegian data for 1991. The weight at age in the catches were weighted by the numbers caught at age by these two countries. Finally the weights were somewhat adjusted to fit the SOP check. As in previous assessments weight at age in the stock was taken to be the same as the weight at age in the catch.

For *S. marinus*, weight-at-age data based on otoliths were available from the Norwegian landings in 1991. Mean weight-at-age for the German landings were found using the Norwegian age-length key and the weight-length relationship W (kilogram) = $0.0000294 \times L^{2.81}$ (cm). The weight at age in the catches were weighted by the numbers caught at age by Germany and Norway. A final SOP check showed a good fit with the nominal catch.

6.4 Age at Maturity (Table 6.12)

Maturity-at-age ogives for *S. mentella* from research vessels, sexes combined, have been made by Russia for several time periods. The average ogive for 1975-1983 has been used for the years 1976-1983. Then, for 1984-1990 a three-year running average has been used, while for 1991 an average of the 1990 and 1991 ogives in Table 6.12 was adopted.

A maturity ogive was not available for *S. marinus*, and a knife-edge maturity at age 15 was assumed.

6.5 Survey Results (Table 6.9-6.10)

The international 0-group fish survey carried out in the Barents Sea in August-September since 1965 does not distinguish between the species of redfish, and the survey design has also improved during the 27 years this survey has been conducted. The indices for the 1980s should, therefore, not be directly compared with those from the 1960s and early 1970s. A great reduction in the abundance of 0-group redfish was observed during the survey in 1991, and preliminary reports from the ongoing survey this year point to a similar low index for 1992 (Table 6.9).

The only surveys directed towards *S. mentella* are the Russian trawl/acoustic survey on the spawning grounds north of 70° N in March-April, and a pilot Norwegian trawl/acoustic survey in April 1992 on the spawning grounds from 62°N to 74°N. The other investigations on redfish are made during surveys mainly directed for other species.

Since 1981, a stratified random bottom trawl survey has been carried out by Norway in February in the Barents Sea. This has been combined with a synoptic acoustic survey. With regard to redfish, reliable comparable results from year to year from these investigations only exist back to 1987, so the time series is too short to tell whether the observed numbers are at a historical low or high level, and no age distribution has been presented. Furthermore, the bottom trawl indices have not been corrected for the change from bobbins to rock-hopper gear and this may have had an effect on the youngest fish. However, the estimate of total numbers for *S. mentella* in 1992 show little change from the year before. This is mainly caused by a promising high index for specimens less than 17 cm. The estimates from both surveys in 1992 also indicate a stable stock situation for *S. marinus* within the investigated area.

Since 1981, a stratified random bottom trawl survey has also been carried out by Norway in September in the Svalbard and Bear Island areas, and a combined trawl/acoustic survey is implemented into the 0-group survey covering both the Svalbard and the Barents Sea regions. The abundance indices for *S. mentella* in 1991 confirmed the improved recruitment earlier observed in the survey. Both surveys also indicate an improved stock situation of *S. marinus* in this area.

In the years 1986-1988, the USSR carried out a trawl/acoustic survey in March-June on the *S. mentella* spawning grounds near Bear Island. The results indicated a reduction in biomass from 90,000 t in 1986 to 60,000 t in 1987 and 30,000 t in 1988. In 1989 the USSR carried out a similar survey in March which estimated the biomass to be about 111,000 t. However, the surveyed area had been extended compared to previous

years, and a large proportion of immature fish are included in the 1989 estimate. In 1990, the USSR carried out this trawl/acoustic survey in the latter half of April on the *S. mentella* spawning grounds southwest of Bear Island. The investigated area was very limited, and the results are not presented in this report because of difficult and uncertain comparisons with previous years. In 1991 no such survey was conducted. In 1992 Russia conducted a survey in March-April, covering the area from the Fugloy Bank to 76°N and from 12°E to 25°E. The area investigated was larger than in previous years, and the total and spawning biomasses were estimated to 217,000 t and 113,000 t, respectively. The results confirmed that the 1982-year class is the strongest in the stock at the moment.

Young redfish is also covered during a Russian bottom trawl groundfish survey in the Barents Sea and Svalbard regions in October-November. These results have been used as the basis for estimating the recruitment in the assessment in recent years (Table 6.10).

6.6 Recruitment (Tables 6.9-6.11)

There are still large discrepancies between the international 0-group fish survey data (Table 6.8) and the data from the USSR bottom trawl survey on *S. mentella* concerning the 1+ - 6+ groups (Table 6.9). However, the strength of the 1963-1966 and 1969-1971 year classes has been confirmed by later years' assessments.

The data on *S. mentella* from the Russian bottom trawl survey (Table 6.10) were used as input to the recruitment program RCRT3. The results are given in Table 6.11 for two kinds of regressions between survey indices and VPA. The predictive (P) regression gave lower standard errors than the calibrated (C) regression. Problem with the age reading may also mask the real year class strengths. The abundances of the different year classes in the Russian survey last spring were back calculated to abundance at age 6, taking both natural mortality and landings into account (Table 6.10 and Figure 6.1). The resulting relative year class strengths were finally adjusted to the overall level from the RCT3 P-regression. The recruitment at age 6 in 1990 and later has been set to 80 millions.

6.7 Assessment of *Sebastes mentella*

6.7.1 Fishing mortalities - VPA (Tables 6.18-6.22, Figures 6.3A-6.3B)

Russian effort and catch data from the trawl fishery (Table 6.13) for ages 9-17 was used as input to the tuning method. The results from the tuning are shown in Table 6.14. A separable VPA for ages 9-19 was then run with terminal F adjusted to give a mean F for ages 10-15 equal to that from the tuning (Table 6.15). An automatic

weighting was adopted. A plot was made of average fishing mortality (ages 10-15) against total international effort in Russian PST units (Figure 6.2). The points for the years 1985-1991 indicate a linear relationship. The final VPA was made using the F_s estimated from terminal populations from the separable VPA for the ages 12-19. Input F_s for ages 6-11 were set to give the initial population numbers estimated as described in Section 6.6. Table 6.18 gives the final estimates of fishing mortality, and the corresponding estimates of stock numbers and biomass are given in Tables 6.19-6.21. Although the fishing mortality the last year seem to fluctuate from assessment to assessment, it converges fairly rapidly to a level that is confirmed from year to year, and the plots shown in Figure 6.3 also show reasonable biological and fishing relationships.

A summary of the historic series of landings, fishing mortality, stock biomass and recruitment is given in Table 6.22.

6.7.2 Projection of stock biomass and catch (Tables 6.23-6.24)

Input data used in the catch predictions are shown in Table 6.23. Population numbers in 1992 are those calculated by VPA for age groups 7 and older. For the 1985-1988 year classes the strength at age 6 has been set equal to 80 millions. The separable fishing pattern was used as input for ages 12 and older in the prediction. For ages 6-11 the fishing pattern for 1991 was used since this corresponded better to the expected stock level of these youngest ages. However, since the fishing mortality of age 9 in 1991 was low, probably due to the strength of the 1982-year class, the input for this age was set to the same level as that for ages 8 and 10, i.e. 0.07. The maturity ogive is the 1990-1991 average calculated from Table 6.11. Weight-at-age in the catch has been set equal to the average weight-at-age from the catches in 1990 and 1991. Weight-at-age in the stock has been set equal to the weight-at-age in the catch.

Yield and spawning stock biomass-per-recruit curves were calculated using the above data (Figure 6.3c). $F_{0.1}$ and F_{max} were estimated to be 0.09 and 0.23, respectively. In last year's assessment a stock-recruitment plot was made which estimated $F_{high}=0.31$, $F_{med}=0.18$, and $F_{low}=0.02$.

Results of the catch predictions are given in Table 6.24. If the expected catch of 20,000 t in 1992 is taken, the fishing mortality will be reduced compared with 1991. Catch predictions for 1993 have been made for the biological reference points and for fishing mortality being maintained at both the 1991 and 1992 levels.

6.8 Assessment of *Sebastes marinus*

Trawl effort and corresponding catch at age existed for Norwegian trawlers for 1986-1991 (Table 6.26). This time series shows artificial variations in catch at age due to variable availability of age-length keys to convert Norwegian catch at length, accounting for 90% of the total landings, to catch at age. The Working Group still considered the time series too short to give realistic stock estimates. A new series based on otolith readings is being built up. However, the existing data were used as input to the Laurec-Shepherd tuning. Although the summary statistics (Table 6.27) showed acceptable standard errors for some ages, the fishing mortalities from the tuning revealed no consistency compared to last year (Table 6.28). It was therefore again concluded that no meaningful assessment could be made.

SHOT forecasts for this stock are given in Tables 6.29 and 6.30 for two options of recruitment. In these forecasts the Y/B ratio has been set to make the estimated landings correspond with the actual ones. The actual landings have also been used as recruitment indices, i.e., the assumption has been made that the landings reflect the recruitment directly. As input for G-M (G is growth-rate and M is natural mortality, $M=0.1$) the growth rate of the ages 12 to 20 has been calculated. The result was $G-M = -0.05$, i.e. the fishery is based on the recruitment. Since for fish older than about 12 years the natural mortality (if correct) is higher than the growth (dependant on the age reading), fishing more than the recruitment will then reduce the stock.

Dependant on the choice of input for the recruitment, the results indicate that catches in the short term will decrease to a level of 10,000-16,000 t.

7 GREENLAND HALIBUT IN SUB-AREAS I AND II

7.1 7.1 Status of the Fisheries

7.1.1 Landings prior to 1991 (Tables 7.1-7.4, Fig. 7.3A)

Nominal catches by country for Sub-areas I and II combined are presented in Table 7.1. The nominal catches by country for Sub-area I and Divisions IIa and IIb separately are shown in Tables 7.2-7.4. Revised landings for 1990 were 22,755 t. The preliminary figure of total catch in 1991 is 27,152 t; an increase of about 33% and 19% compared with the 1989 and 1990 level, respectively. This is 1,152 t more than expected by last year's Working Group. Nominal catches increased in both sub-areas, and more than 50% of the total catch was taken in Division IIb.

7.1.2 Expected landings in 1992

Due to the low level of this stock the fishery in 1992 has been strongly regulated, and a direct trawl fishery has been forbidden. The catch in 1992 is therefore expected to be taken by long line and gill net in addition to a legal percentage by-catch in the trawl fishery for other species. Based upon reported catches from the first seven months of the year, it is estimated that the 1992 total catch will be about 7,000 t. It is expected that Russia will take 500 t and Norway 6,000 t of the total catch. The recommended and agreed TAC will therefore probably be overfished by about 1,000 t.

7.1.3 Effort and catch-per-unit-effort (Table 7.5)

Catch-per-unit-effort (CPUE) data for 1991 were only available for Norwegian trawlers. The CPUE shows a continuous decrease since 1988, and the level in 1991 was estimated to be 22% lower than the year before. The catch rate of seven years and older fish (CPUE 7+) is, however, at the same level as in 1990, but this is only 50% of the catch rates in the middle of the 1980s. A huge increase in the effort is observed in the most recent years.

7.2 Catch in Numbers at Age (Table 7.11)

The catch-at-age data for 1990 were updated by adjusting the age composition used in the previous assessment to final catch statistics for that year. Catch-at-age data for 1991 were available for the Norwegian fisheries accounting for about 89% of the landings. The Norwegian catch-at-age was finally raised to the total international landings, assuming that landings by other countries having the same age composition as that for Norway.

7.3 Weight-at-Age (Table 7.12)

A constant set of weight-at-age data is used for all years in the period 1970-1978. For subsequent years annual estimates, weighted by the numbers caught at age by each country, are used. Mean weight-at-age data from the Norwegian fishery in 1991 was used for the total catch. A final SOP check showed good fit with the nominal catch.

7.4 Age at Maturity (Table 7.10)

The spawning stock biomasses for 1983-1987 were calculated by application of an average maturity ogive derived from USSR data for the period 1983-1987. As explained in the Working Group report for 1990, the same ogive was applied to the period 1970-1982. For 1988 and 1989 a three-year running average has been used, while for 1990 and 1991 the average of the 1989 and 1990 ogives was adopted (Table 7.10). During the period 1984-1990 the USSR data on maturity have been

collected at different times of the year. According to the Russian scientists the best time of the year to sample such data on Greenland halibut is in August-February.

7.5 Survey Results (Table 7.6)

The index for 0-group Greenland halibut in the International 0-group survey in the Barents Sea and Svalbard area since 1970 showed a sudden drop in 1988 and was in 1991 at the lowest level ever recorded (see text table below). Since the survey design was improved at the end of the 1970s, the survey has been conducted at the same time and following the same procedures every year, although the timing of this survey with regard to Greenland halibut may not be optimal. The fact that four consecutive bad year class indices of this stock have never been observed before, gives cause for concern about the recruitment.

Year	78	79	80	81	82	83	84
O-group index	35	23	12	38	17	16	40

Year	85	86	87	88	89	90	91
O-group index	36	55	41	8	5	2	1

Norwegian stratified random bottom trawl surveys have been conducted annually in both the Svalbard and the Barents Sea since 1981. Whereas the surveys cover the main nursery area of Greenland halibut, they do not fish beyond depths of 600 m, and thus do not cover the whole geographical distribution of the stock. Abundance indices of the different age groups and of fish less than 20 cm in the Svalbard area are presented in Table 7.6. Some of the fluctuations observed clearly are not indicators of stock size and may be an artefact of incomplete survey coverage, migration, and the age-length key used. On the youngest fish there may also be an effect of the change from "bobbins" to "rock-hopper" gear from 1988 to 1989. The older data have not been adjusted to account for this change. However, the clear decrease of 1 and 2 year old fish corresponds to the drop in 0-group indices and should be taken as a warning of possible poor recruitment to the fishery in the near future.

Also indices (on length) from the Norwegian bottom trawl survey in the Barents Sea in February in 1990-1992 (unpublished data) show a decrease of fish less than 35 cm.

In October-November 1990 three USSR research vessels conducted a stratified bottom trawl survey directed towards Greenland halibut (Shevelev and Lepeshevich 1991). This survey focused on the area along the conti-

mental slope between 71° - 80°N and 5° - 18°E, and depths down to 900 m. The numbers and biomass were estimated to 59 mill. specimens and 55,000 t, respectively. Fish 4-7 years old (36-55 cm) dominated. A similar survey was conducted by Russia at the same time in 1991 covering a wider area (east to 35°E). Comparable estimates to those from the 1990-survey gave 17 mill. specimens and a biomass of 17,000 t. No age distribution was available, but 36-50 cm fish dominated. Since the estimates of total number (63 mill.) and biomass (73,000 t) from the 1991 survey were higher than in 1990, i.e. a major part of the stock was in 1991 observed in the area (19°E to 35°E) not covered in 1990, this may be due to a change in distribution from one year to another.

7.6 Recruitment

The results for 1-6 year old fish from the Norwegian bottom trawl survey and the 0-group survey were used as input to the ICES RCT3 program to estimate the abundance of the 1986-1990 year classes. The results showed a bad and variable statistical fit between the survey indices and VPA, and the mean therefore contributed very much to the final estimates. Due to this lack of fit a simple average of the recruitment at age 3 from the VPA for the years 1982-1988, i.e., 27 millions, was taken as the recruitment at age 3 in 1989 to 1991.

7.7 Assessment

7.7.1 Estimation of fishing mortality (Tables 7.7-9, 7.13-7.17 and Figures 7.1-7.2)

Trawl effort data and the corresponding catch-at-age data were available for Norwegian trawlers for the years 1979-1991. The data (Table 7.7) for the Norwegian fleet for age groups 7-12 and the Norwegian Svalbard survey for age groups 3-7, were used in the VPA tuning module, and the results are given in Table 7.8. The Laurec-Shepherd method was used in the tuning. The reference ages of F used were 6-10. A plot was made of average fishing mortality (ages 6-10) against total international effort (Figure 7.1). The plot confirms the change in the fishery from 1989 and onwards. Figure 7.2 shows the development in effort and fishing mortality from 1982 and onwards.

A separable VPA was run with the input terminal F adjusted so that F_{6-10} for 1991 was equal to F_{6-10} for that year as indicated by the tuning. Weights from the automatic weighting were adopted. The matrix of residuals from the separable VPA is given in Table 7.9. The input Fs in 1991 for ages 3 and 4 were finally adjusted to give the average (1982-1988) recruitment (27 millions at age 3) in 1989-1991.

The age range in the VPA was reduced by one year compared to previous assessments making age 15 the

plus group. The fishing mortalities on the older age groups for the years 1970-1980 were therefore adjusted by running separable VPA for different year ranges within that time period. Table 7.13 gives the final estimates of fishing mortality, and the corresponding estimates of stock numbers, stock biomass and spawning stock biomass are given in Tables 7.14 to 7.16, respectively.

A summary of the historic series of landings, fishing mortality, stock biomass and recruitment is given in Table 7.17.

Two additional tunings were run using the Extended Survivors Analysis and the ADAPT framework. The methods gave $F_{6-10} = 0.31$ and 0.42, respectively. The effort in the Norwegian trawl fishery nearly doubled from 1989 to 1991 resulting in a substantial increase in the total effort. The fishing mortalities estimated by these two tuning methods did not reflect this recent trend in the fishing effort, and these analyses were therefore not used for the final assessment.

7.7.2 State of the Stock

The fishing mortality (ages 6-10) was relatively high in 1970-1971 and in 1976 when it was about 0.41 (Table 7.13). It then fell to less than 0.20 for three years before it started increasing again towards a peak in 1988 of 0.40. After a minor drop in 1989, an increase to well above the 1988-level is estimated for 1991. The level of the fishing mortality estimated this year is below that estimated by last year's Working Group, probably because of a revision of the landings and somewhat higher indices in last year's bottom trawl survey of 5-8 year old fish. Assuming that the expected catch of 7,000 t in 1992 will be taken, that will result in a fishing mortality of 0.15. This is a result of strong regulations of the fishery in order to rebuild the stock. Until 1976 the spawning stock was estimated at more than 100,000 t, and in the years 1977-1985 the spawning stock has been stable at a level of 60,000-80,000 t (Table 7.16, Figure 7.3B). However, from 1983, we observe a decreasing trend in spawning stock to a level of about 40,000 t at present. This reduction is consistent with the decline in the combined USSR and Norwegian CPUE from 1985 to 1991 (Table 7.5).

7.8 Catch Predictions (Table 7.18-7.22)

Input data used in the catch predictions are shown in Table 7.18. Population numbers in 1992 are those calculated by VPA for age groups 6 and older. For the 1989-1991 year classes the strength at age 3 has been set equal to the average level used in last year's assessment, i.e. 25 millions. In addition, an option with low recruitment of 10 million specimens has been given. The exploitation pattern used is that from the separable VPA

(Tables 7.9). The maturity ogive is the 1989-1990 average which also was used for 1990 in the VPA. Weight at age in both the catch and the stock has been set equal to the weight at age in the catch averaged for the years 1990 and 1991.

Yield- and spawning stock biomass-per-recruit have been calculated using the above data, and the results have been plotted in Figure 7.3C. The values of $F_{0.1}$ and F_{\max} are 0.13 and 0.29, respectively. Using the stock-recruitment plot from last year's assessment the values of F_{low} , F_{med} and F_{high} have been taken as 0.07, 0.23 and 0.32, respectively.

Short- (up to 1994) and medium term (up to 1997) catch predictions are given in Tables 7.19-7.22 and Figure 7.3D. To take the expected catch of 7,000 t in 1992 will reduce the fishing mortality to a low level. Catch predictions for 1993 have been made for the biological reference points and for fishing mortality being maintained at both the 1991 and the expected 1992 level.

Keeping the fishing mortality at a low level, a slight increase in the spawning stock is expected even with a low recruitment. On the other hand, if we go back to the 1991-level (F_{91}), we will get a further reduction in the spawning stock even with a high recruitment.

7.9 Comments on the Assessment

It is the unanimous opinion of the Working Group that the continuous large reduction in CPUE, declining spawning stock biomass, and indications of weak year classes in the 0-group survey in the four most recent years must be taken into account when TAC recommendations are made. It is also decisive for the near future development of the stock that the recommended TAC will be accepted and enforced, as was done in 1992.

8 RECOMMENDATIONS

8.1 Age Readings

The Working Group agreed that the preliminary work on the ageing problems for the North-East Arctic cod presented at the meeting had been very useful. Standardization of age readings between all readers involved is important for the precision of the assessment. The Working Group, therefore, recommends that this work be continued, both on a routine basis (e.g., exchange of otoliths) and through workshops for representatives of the institutes involved.

8.2 Methods Standardization

The experience of the Working Group in recent years is that too much time is spent on discussing methods,

procedures and technicalities during the meetings. Many of these things might have been standardized if a more thorough analysis and discussion had been undertaken, but at Working Group meetings with the pressure to produce a valid assessment, there is not sufficient time. Standardization would prevent year-to-year changes in the way assessments are carried out and would allow more time for other discussion, or, alternatively, shorter working group meetings. The Working Group suspects that the situation is similar in some other working groups and recommends that a workshop is arranged as soon as possible on standardization of assessment procedures for Arctic demersal stocks, primarily cod and haddock.

¹Preliminary figures.

²Norwegian data - t per 1,000 t*hrs fishing.

³United Kingdom data - t per 100 t*hrs fishing.

⁴Russia data - t per hr fishing.

Period	Sub-area I	Divisions IIa and IIb
1960-1973	RT	RT
1974-1980	PST	RT
1981-	PST	PST

Vessel type:

RT = side trawlers, 800-1000 HP.

PST = stern trawlers, up to 2000 HP.

⁵Norwegian data - t per gillnet boat week in Lofoten.

⁶Spanish data - t per hr fishing.

⁷Data for the first half of the year.

Table 3.14

Analysis by RCT3 ver3.1 of data from file :

rcrt-dat.rci

NORTHEAST ARCTIC COD : recruits as 3 year-olds (inc. data for ages 0,1,2 & 3)

Data for 16 surveys over 35 years : 1957 - 1991

Regression type = C
Tapered time weighting applied
power = 3 over 20 years
Survey weighting not applied

Final estimates shrunk towards mean
Minimum S.E. for any survey taken as .20
Minimum of 3 points used for regression

Forecast/Hindcast variance correction used.

Yearclass = 1987

Title : Cod in the North-East Arctic (Fishing Areas I and II) (run n

Separable analysis

from 1982 to 1991 on ages 3 to 14

with Terminal F of .240 on age 8 and Terminal S of 1.000

Initial sum of squared residuals was 110.085 and
final sum of squared residuals is 31.980 after 93 iterations

Table 4.12 North East Arctic HADDOCK.
Recruitment analysis.

Analysis by RCT3 ver3.1 of data from file :

had-1.rcr

NORTHEAST ARCTIC HADDOCK : recruits as 3 year-olds (inc. data for ages 0,1,2 & 3

Data for 10 surveys over 35 years : 1957 - 1991

Regression type = P

Tapered time weighting applied

power = 3 over 20 years

Survey weighting not applied

Final estimates not shrunk towards mean

Estimates with S.E.'S greater than that of mean included

Minimum S.E. for any survey taken as .00

Minimum of 5 points used for regression

Forecast/Hindcast variance correction used.

Yearclass = 1987

Table 4.20

Title : Haddock in the North-East Arctic (Fishing Areas I and II)

Separable analysis
from 1981 to 1991 on ages 3 to 13
with Terminal F of .255 on age 6 and Terminal S of .700

Initial sum of squared residuals was 120.541 and
final sum of squared residuals is 83.911 after 103 iterations

1989	131	59.8	295
1990	96	60.4	262
1991	105	52.3	249

¹ No. of vessels 20-24.9 m.² Hours trawling ('000).³ Trawl indices scaled up to give the same average for 1977-1990 as the purse seine indices (i.e. x 2.75) before adding the two.

Effort indices for both categories raised to represent total Norwegian landings for the gear.

Table 5.6 North-East Arctic SAITHE. Results from the Norwegian acoustic survey in October-November. Numbers in millions.

Year	Ages					Total
	2	3	4	5	6+	
1985 ¹	7.8	12.3	6.1	1.2	+	27.4

Title : Saithe in the North-East Arctic (Fishing Areas I and II) (ru

Separable analysis

from 1981 to 1991 on ages 2 to 10

with Terminal F of .391 on age 4 and Terminal S of .550

Initial sum of squared residuals was 60.581 and
final sum of squared residuals is 19.906 after 102 iterations

Table 6.15

Title : *Sebastes mentella* in the Norwegian Sea, Spitzbergen and Bear

At 1/09/1992 15:52

Separable analysis
from 1982 to 1991 on ages 9 to 18
with Terminal F of .600 on age 13 and Terminal S of 1.000

Initial sum of squared residuals was 89.613 and
final sum of squared residuals is 23.652 after 61 iterations

Title : Greenland Halibut in the North-East Arctic (Fishing Areas I)

At 31/08/1992 18:48

Separable analysis
from 1982 to 1991 on ages 3 to 14
with Terminal F of .610 on age 8 and Terminal S of 1.000

Initial sum of squared residuals was 241.703 and
final sum of squared residuals is 76.337 after 87 iterations

APPENDIX I

Plots of Survey Indices and VPA (Figures A.1 to A.15)

Time series of survey indices at age, used in the tuning analyses, were plotted along with the accepted VPA to determine how well the age-structured survey results reflected trends in actual stock abundance. This was completed for both cod and haddock. For comparison purposes each time series, for both VPA and survey indices, was scaled to its representative mean. The survey indices at age reflected the trends in stock abundance quite well, although some inconsistencies were apparent for some surveys. It was observed that strong year classes were most influential in determining relationships between survey indices and VPA for both species and at virtually all ages.

Time series of recruitment at ages 0, 1 and 2 for cod, were also plotted along with VPA results at age 3 (Figures A.12-A.15). The recruitment data plotted were not those used in the RCT3 program, but were derived from the same surveys used in the tuning. The new indices appear to more adequately reflect trends in year class strength as described by the VPA than the indices used in the RCT3 program. Results from the original analysis were used for catch predictions for this assessment. During the next assessment of the stock it will be decided if recruitment indices derived from the surveys used for tuning will be used to determine year class strength for predictions.
