# Report of the <br> Arctic Fisheries Working Group 

4-13 May 2004
ICES, Copenhagen

This report is not to be quoted without prior consultation with the General Secretary. The document is a report of an Expert Group under the auspices of the International Council for the Exploration of the Sea and does not necessarily represent the views of the Council.

## Contents

INTRODUCTION .....  1
Participants ..... 1
Terms of Reference ..... 1
General comment ..... 2
Management strategy for NEA cod and haddock ..... 2
Unreported landings ..... 2
Other inadequacies in the data and possible deficiencies in the assessments ..... 2
Use of age- and length structured models in assessment (Fleksibest) ..... 4
ICES Quality Handbook .....  5
Scientific Presentations ..... 5
1 ECOSYSTEM INFLUENCES ON BARENTS SEA FISH STOCKS ..... 8
1.1 Climate considerations in the Barents Sea .....  8
1.1.1 Temperature and ice conditions (Figures 1.1-1.2) ..... 8
1.1.2 Inflow of Atlantic water .....  8
1.1.3 Predicting Barents Sea temperature (Figure 1.2) ..... 9
1.1.4 Climatic effects on plankton (phyto,- zoo- and ichtyoplankton) .....  9
1.2 Zooplankton ..... 10
1.2.1 Sampling and abundance (Figure 1.3-1.4) ..... 10
1.2.2 Prediction of year-to-year dynamic of krill abundance (Figure 1.5) ..... 10
1.3 Trophic interactions ..... 11
1.3.1 Predicting capelin biomass (Tables 1.1-1.2) ..... 11
1.3.2 Predation by cod (Table 1.3-1.6, Figure 1.6) ..... 11
1.3.3 Predation by other fish species ..... 12
1.3.4 Predation by mammals (Table 1.7) ..... 12
1.4 Ecosystem data for potential use in the stock assessment and projections ..... 13
1.4.1 Recruitment ..... 13
1.4.1.1 Recruitment models (Table 1.8, Figure 1.7) ..... 13
1.4.2 Growth ..... 14
1.4.2.1 Prediction of NEA cod growth rate (Table 1.9) ..... 14
1.4.2.2 Effects of capelin and temperature on maturation of $\operatorname{cod}$ (Table 1.10, Figure 1.8-1.11) ..... 14
1.4.3 Natural mortality ..... 15
1.4.3.1 Cannibalism mortality for cod (Table 1.11) ..... 15
2 NORWEGIAN COASTAL COD IN SUB-AREAS I AND II ..... 32
2.1 Status of the Fisheries ..... 32
2.1.1 Landings prior to 2003 (Tables 2.9, 2.19, Figure 2.2) ..... 32
2.1.2 Expected landings in 2004 (Figure 2.5) ..... 32
2.2 Status of Research ..... 33
2.2.1 Survey results (Tables 2.1.B, 2.2, 2.3, 2.4, 2.5, 2.6, 2.7) ..... 33
2.2.2 Age reading and stock separation ..... 33
2.2.3 Weight-at-age (Tables 2,5 2.11) ..... 33
2.2.4 Maturity-at-age (Tables 2.6, 2.12) ..... 33
2.3 Data Used in the Assessment ..... 34
2.3.1 Catch-at-age (Table 2.9) ..... 34
2.3.2 Weight-at-age (Table 2.10, 2.11) ..... 34
2.3.3 Natural mortality ..... 34
2.3.4 Maturity-at-age (Tables 2.6, 2.12) ..... 34
2.3.5 Tuning data (Table 2.7) ..... 34
2.3.6 Prediction data (Tables 2.20, 2.21, 2.22) ..... 34
2.4 Methods Used in the Assessment. ..... 35
2.4.1 VPA and tuning (Table 2.8) ..... 35
2.5 Results of the Assessment ..... 35
2.5.1 Fishing mortality and VPA (Tables 2.13-2.19, Figure 2.2) ..... 35
2.5.2 Recruitment (Tables 2.7, 2.15, 2.19, 2.20). ..... 36
2.6 Catch Options for 2005 and Management Scenarios (Tables 2.22-2.23, Figure 2.2) ..... 36
2.7 Biological reference points ..... 36
2.7.1 Biomass reference points (Figure 2.4) ..... 36
2.8 Comments to the Assessment ..... 37
2.8.1 A comparison of the assessment results and the survey results (Figure 2.1) ..... 37
2.8.2 Comparison of this years assessment with last years assessment (Figure 2.3) ..... 37
2.8.3 Uncertainties in the assessment ..... 37
2.8.4 Management considerations ..... 37
2.9 Response to ACFM technical minutes ..... 37
3 NORTH-EAST ARCTIC COD (SUB-AREAS I AND II) ..... 57
3.1 Status of the fisheries ..... 57
3.1.1 Historical development of the fisheries (Table 3.1) ..... 57
3.1.2 Landings prior to 2004 (Tables 3.1-3.3, Figure 3.1) ..... 57
3.1.3 Expected landings in 2004 ..... 57
3.2 Status of research ..... 57
3.2.1 Fishing effort and CPUE (Table A1) ..... 57
3.2.2 Survey results (Tables A2-A5, A10-A11, A14-A16) ..... 57
3.2.3 Age reading ..... 58
3.2.4 Length and Weight at age (Tables A6-A9, A12-A13) ..... 58
3.2.5 Maturity at age (Table 3.5) ..... 59
3.2.5.1 Status of research on reproductive potential of NA cod ..... 59
3.2.5.2 Potential causes of interannual variation in maturity ogives ..... 59
3.3 Data used in the assessment ..... 60
3.3.1 Catch at age (Tables 3.8, 3.9 and 3.10) ..... 60
3.3.2 Weight at age (Tables 3.4 and 3.11-3.12) ..... 60
3.3.3 Natural mortality ..... 61
3.3.4 Maturity at age (Tables 3.5 and 3.13) ..... 61
3.3.5 Tuning data (Tables 3.14 and 3.15) ..... 61
3.3.6 Recruitment indices (Tables 3.6 and 3.7) ..... 61
3.3.7 Cannibalism ..... 61
3.3.8 Prediction data (Tables 3.23 and 3.28, Figure 3.2 and 3.14a) ..... 62
3.4 Methods used in the assessment ..... 62
3.4.1 VPA, tuning and sensitivity analysis ..... 62
3.4.2 Including cannibalism in the VPA (Tables 3.16-3.20, 3.22) ..... 63
3.5 Results of the assessment ..... 64
3.5.1 Fishing mortalities and VPA (Tables 3.21-3.26, Figures 3.1) ..... 64
3.5.2 Recruitment (Table 3.6-3.7) ..... 64
3.6 Reference points. ..... 64
3.6.1 Biomass reference points (Figure 3.1) ..... 64
3.6.2 Fishing mortality reference points ..... 64
3.7 Catch options (Table 3.29-3.30) ..... 64
3.8 Medium-term forecasts and management scenarios ..... 65
3.8.1 Adopted harvesting strategy ..... 65
3.8.2 Results ..... 65
3.8.3 Management considerations ..... 65
3.9 Comments to the assessment (Figures 3.2-3.6 and 3.13-3.16, Table 3.15 and 3.31) ..... 65
3.9.1 Comparison of this year's assessment with last year's assessment ..... 66
3.9.2 Comparison with other sources of stock indicators ..... 66
3.10 Alternative assessment methods (Fleksibest) ..... 67
3.10.1 Introduction ..... 67
3.10.2 Stock assessment using Fleksibest ..... 67
3.10.2.1 Model structure ..... 67
3.10.2.2 3.10.2.2 Data used ..... 67
3.10.2.3 Model assumptions ..... 68
3.10.2.4 Optimization algorithm ..... 69
3.10.2.5 Changes from last year ..... 69
3.10.2.6 Estimates of parameters outside the model ..... 69
3.10.3 Results from the assessment ..... 70
3.10.4 Retrospective analysis ..... 70
3.10.5 Use of Fleksibest for predictions ..... 70
3.10.5.1 Comments to the prognosis ..... 71
3.10.6 Reference points related to Fleksibest ..... 71
3.11 Comparison of results from XSA and Fleksibest. ..... 71
3.11.1 Comparison of the assessments ..... 71
3.11.2 Comparison of the predictions ..... 71
3.12 Evaluation of harvest control rule ..... 71
3.12.1 Introduction ..... 71
3.12.2 General considerations for evaluation of harvest control rules ..... 72
3.12.3 Approaches for Harvest control rule evaluation presented to the Working Group ..... 72
3.12.3.1 Long-term stochastic simulation (WD3) ..... 72
3.12.3.2 Stochastic simulations based on historical data (WD 18) ..... 75
3.12.4 Comparison of the approaches ..... 77
3.12.5 Conclusions ..... 77
3.12.6 Further work on management strategies for NEA cod. ..... 78
4 NORTHEAST ARCTIC HADDOCK (SUBAREAS I AND II) ..... 205
4.1 Status of the Fisheries ..... 205
4.1.1 Historical development of the fisheries ..... 205
4.1.2 Landings prior to 2004 (Tables 4.1-4.3, Figure 4.1A) ..... 205
4.1.3 Expected landings in 2004 ..... 206
4.2 Status of Research ..... 206
4.2.1 Fishing effort and CPUE (Table 4.2) ..... 206
4.2.2 Survey results (Tables B1-B4) ..... 206
4.2.3 Weight-at-age (Tables B5, B6) ..... 206
4.3 Data Used in the Assessment ..... 207
4.3.1 Catch-at-age (Table 4.7) ..... 207
4.3.2 Weight-at-age (Tables 4.8-4.9, Table B.6) ..... 207
4.3.3 Natural mortality (Table 4.10) ..... 207
4.3.4 Maturity-at-age (Table 4.4 and 4.11) ..... 207
4.3.5 Data for tuning (Table 4.12) ..... 207
4.3.6 Recruitment indices (Table 4.5) ..... 207
4.3.7 Prediction data (Table 4.19, Table 4.6) ..... 207
4.4 Methods Used in the Assessment. ..... 208
4.4.1 VPA and tuning (Table 4.10, Table 4.12, Table A16, Figures 4.5-4.8) ..... 208
4.4.2 Recruitment (Tables 4.5-4.6) ..... 209
4.5 Results of the Assessment ..... 209
4.5.1 Fishing mortality and VPA (Tables 4.10, 4.13-4.18 and Figures 4.1A-D, 4.5-4.7) ..... 209
4.5.2 Recruitment (Tables 4.6, 4.15 and Figure 4.1C) ..... 209
4.5.3 Yield per Recruit, SSB per Recruit (Table 4.19-4.20, Figures 4.2-4.3) ..... 210
4.5.4 Catch options for 2003 (Tables 4.19, 4.21-4.22) ..... 210
4.6 Biological reference points ..... 210
4.6.1 Biomass reference points ..... 210
4.6.2 Fishing mortality reference points (Figure 4.4) ..... 210
4.7 Medium-term simulations ..... 210
4.8 Comments to the assessment and forecasts ..... 210
4.8.1 Changes from last year ..... 211
4.9 Technical minutes from ACFM ..... 211
5 NORTHEAST ARCTIC SAITHE (SUB-AREAS I AND II) ..... 262
5.1 Status of the Fishery ..... 262
5.1.1 Landings prior to 2004 (Tables 5.1-5.2, Figure 5.1) ..... 262
5.1.2 Expected landings in 2004 ..... 262
5.2 Status of Research ..... 263
5.2.1 Fishing Effort and Catch-per-unit-effort (Tables C1-C2) ..... 263
5.2.2 Survey results (Tables C3) ..... 263
5.3 Data used in the Assessment ..... 263
5.3.1 Catch numbers at age (Table 5.3) ..... 263
5.3.2 Weight at age (Table 5.4) ..... 263
5.3.3 Natural mortality ..... 263
5.3.4 Maturity at age (Table 5.14) ..... 263
5.3.5 Tuning data (Table 5.5) ..... 263
5.3.6 Recruitment indices ..... 263
5.3.7 Prediction data (Table 5.14) ..... 264
5.4 Methods used in the Assessment. ..... 264
5.4.1 XSA and tuning (Table 5.6, Figures 5.2A-C, 5.3A-B) ..... 264
5.4.2 Recruitment (Tables 5.8, 5.12-5.13 and C.3, Figure 5.1) ..... 264
5.5 Results of the Assessment ..... 264
5.5.1 Fishing mortalities and VPA (Tables 5.7-5.11, Figures 5.1 and 5.4) ..... 264
5.5.2 Recruitment (Tables 5.12-5.13) ..... 264
5.6 Reference points. ..... 265
5.6.1 Biomass reference points ..... 265
5.6.2 Fishing mortality reference points (Tables 5.14, 5.15, Figures 5.1) ..... 265
5.7 Catch options for 2005 (short term predictions) (Table 5.16) ..... 265
5.8 Medium-term forecasts and management scenarios (Table 5.17A-B, Figures 5.5A-B) ..... 265
5.9 Comparison of this year's assessment with last year's assessment ..... 265
5.10 Comments on the assessment and the forecast ..... 265
5.11 Response to ACFM technical minutes ..... 266
6 SEBASTES MENTELLA (DEEP-SEA REDFISH) IN SUB-AREAS I AND II ..... 300
6.1 Status of the Fisheries ..... 300
6.1.1 Historical development of the fishery ..... 300
6.1.2 Landings prior to 2004 (Tables 6.1-6.4, D1-D2, Figure 6.1) ..... 300
6.1.3 Expected landings in 2004 ..... 300
6.2 Data used in the Assessment ..... 300
6.2.1 Fishing effort and catch-per-unit-effort ..... 301
6.2.2 Catch at age (Table 6.5) ..... 301
6.2.3 Weight at age (Table 6.6) ..... 301
6.2.4 Maturity at age (Table D8) ..... 301
6.2.5 Survey results (Tables A14, D3-D7, Figures 6.2-6.6) ..... 301
6.3 Results of the Assessment ..... 302
6.4 Comments to the assessment ..... 302
6.5 Biological reference points ..... 302
6.6 Management advice ..... 303
6.7 Response to ACFM technical minutes ..... 303
7 SEBASTES MARINUS (GOLDEN REDFISH) IN SUB-AREAS I AND II ..... 323
7.1 Status of the Fisheries ..... 323
7.1.1 Historical development of the fishery ..... 323
7.1.2 Landings prior to 2004 (Tables 7.1-7.5, D1 and D2, Figure 7.1) ..... 323
7.1.3 Expected landings in 2004 ..... 323
7.2 Data Used in the Assessment ..... 323
7.2.1 Fishing effort and catch-per-unit-effort (Tables D9, Figure 7.2) ..... 323
7.2.2 Weight at Age (Table 7.7) ..... 324
7.2.3 Maturity at age ..... 324
7.2.4 Survey results (Tables D10a,b-D11a,b-D12, Figures 7.3a,b-7.4a,b) ..... 324
7.3 Results of the Assessment ..... 324
7.4 Biological reference points ..... 325
7.5 Response to ACFM technical minutes ..... 325
8 GREENLAND HALIBUT IN SUBAREAS I AND II. ..... 338
8.1 Status of the fisheries ..... 338
8.1.1 Landings prior to 2003 (Tables 8.1-8.5, E10) ..... 338
8.1.2 Expected landings in 2004 ..... 338
8.2 Status of research ..... 339
8.2.1 Survey results (Tables A14, E1-E8) ..... 339
8.2.2 Commercial catch-per-unit-effort (Table 8.6 and E9) ..... 340
8.2.3 Age readings ..... 340
8.3 Data used in the assessment ..... 340
8.3.1 Catch-at-age (Table 8.7) ..... 340
8.3.2 Weight-at-age (Table 8.8) ..... 340
8.3.3 Natural mortality ..... 340
8.3.4 Maturity-at-age (Tables 8.9) ..... 340
8.3.5 Tuning data ..... 341
8.4 Recruitment indices (Tables A14, E1-E9) ..... 341
8.5 Methods used in the assessment ..... 341
8.5.1 VPA and tuning ..... 341
8.6 Results of the Assessment ..... 341
8.6.1 Results of the VPA (Figure 8.2, Tables 8.11-8.15) ..... 341
8.6.2 Biological reference points ..... 342
8.6.3 Catch options for 2004. ..... 342
8.7 Comparison of this years assessment with last years assessment ..... 343
8.8 Comments to the assessment ..... 343

## Terms of Reference

At its October 2003 meeting ACFM decided the following:

## The Arctic Fisheries Working Group [AFWG] (Chair: Y. Kovalev, Russia) will meet at ICES Headquarters from $4-$

 13 May 2004 to:a) assess the status of and provide catch options for the year 2005 for the stocks of cod, haddock, saithe, Greenland halibut, and redfish in Subareas I and II, taking into account interactions with other species and attempting alternative assessment methods where applicable;
b) evaluate the agreed management strategy for cod and haddock, with special attention to the reference points for spawning stock biomass and fishing mortality;
c) provide specific information on possible deficiencies in the 2004 assessments including, at least, any major inadequacies in the data on catches, effort or discards; any major inadequacies in research vessel surveys data, and any major difficulties in model formulation, including inadequacies in available software. The consequences of these deficiencies for the assessment of the status of the stocks and for the projection should be clarified;
d) comment on this meeting's assessments compared to the last assessment of the same stock, for stocks for which a full or update assessment is presented;
e) document fully the methods to be applied in subsequent update assessments and list factors that would warrant reconsideration of doing an update, and consider doing a benchmark ahead of schedule, for stocks for which benchmark assessments are done.

AFWG will report by 17 May 2004 for the attention of ACFM.

## General comment

Because Barents Sea shrimp assessment will be dealt with by a joint NAFO-ICES pandalus working group, its section is deleted from the AFWG report from this year.

## Management strategy for NEA cod and haddock

At the $31^{\text {st }}$ session of The Joint Norwegian-Russian Fishery Commission the Parties agreed on a new harvesting strategy for Northeast Arctic cod and haddock. An evaluation of this harvesting strategy is ToR b) for the working group. Two working documents considering the evaluation of this rule for cod were presented (WD3 and WD18). The evaluation of the harvest control rule is given in Section 3.12. The evaluation of the harvesting strategy for haddock was postponed.

## Unreported landings

ICES received an official letter from the Norwegian ICES delegate with information about unreported landings of cod in the Barents Sea and Svalbard areas. Quoting from this letter:
"The Norwegian Directorate of Fisheries has with assistance from the Norwegian Coast Guard conducted comprehensive investigations to estimate the total catch of North-East Arctic Cod in the Barents Sea since 2002.

Based on the information available, it seems that the total catch of North-East Arctic Cod in 2002 is about 80.000100.000 tonnes higher than the officially reported catch quantities. The estimate for 2003 is not yet completed, but available information indicates that the extent of over-fishing is about the same quantity as in 2002."

## Other inadequacies in the data and possible deficiencies in the assessments

At recent AFWG meetings it has been recognized that there is growing evidence of both substantial discarding and mis-/un-reporting of catches throughout the Barents Sea for most groundfish stocks in recent years (ICES CM 2002/ACFM:18, ICES CM 2001/ACFM:02, ICES CM 2001/ACFM:19, Dingsør WD 132002 WG, Hareide and Garnes WD 142002 WG, Nakken WD 102001 WG, Nakken WD8 2000 WG, Schöne WD4 1999 WG, Sokolov, WD 92003 WG). During the present meeting, in addition to the Norwegian report on unreported landings in 2002 and 2003, a working document (Sokolov, WD 7) estimating cod discard in the Russian bottom trawl fishery in the Barents Sea in 1983-2002 was presented. The discard was found to be highly variable over time and affected mainly age groups 3 and 4 , and on average over the time period, 6 million individuals, mostly age groups 3 and 4 ( $30-45 \mathrm{~cm}$ ), were annually discarded. On average, this composes about $6 \%$ of the total number of cod caught. Ajiad et al. (WD 24) presents preliminary results on the total cod by-catch in the Norwegian shrimp fishery during 1983-2002 based on data from the Norwegian commercial shrimp landing statistics, data from the Norwegian fishery surveillance agency and the scientific shrimp surveys. The working group was informed about the focus on discards in Norway recently, which resulted in a report to the Norwegian Ministry of Fisheries about possible actions to quantify and reduce the problem. The total effect of the discarding is still very unclear and requires more work before it can be included in the assessments.

Inaccuracies in the catch statistics continue to represent one of the most serious errors in stock assessments. The $32^{\text {nd }}$ Russian-Norwegian Fisheries Commission declared at its meeting in November 2003 that 2004 should be the "Year of control". The Commission has asked the Permanent Russian-Norwegian Committee on Fisheries Management and Control to work out and present a joint report by 1 July 2004 on how to stop unreported landings. To secure that the official landing statistics become reliable, it is important that the responsible authorities intensify their control and estimate the catches and landings by independent methods on a regular basis.

While the area coverage of the winter surveys was incomplete in 1997 and 1998, the coverage was normal for these surveys in 1999-2002. In the autumn 2002 and winter 2003, however, surveys have again been incomplete due to lack of access to both the Norwegian and Russian Economic Zones. This affects the reliability of some of the most important survey time series for cod and haddock and consequently also the quality of the assessments. In some years, the permission to work in the Norwegian and Russian Economic Zones, respectively, has been received so late that the work has been severely hampered, e.g., the Russian survey in autumn 2003. There is no acceptable way around this problem except asking the Norwegian and Russian authorities to give each other's research vessels full access to the respective economical zones when assessing the joint resources, as, e.g., was the case for the Norwegian survey in winter 2004.

In 1992, PINRO, Murmansk and IMR, Bergen began a routine exchange program of cod otoliths in order to validate age readings and ensure consistency in age interpretations (Nedreaas and Yaragina, WD 112003 WG). Later, a similar exchange program was established for haddock otoliths. Once a year the age readers come together and evaluate discrepancies, which are seldom more than 1 year, and the results show an improvement over the time period from $30 \%$ to $15 \%$ discrepancies for cod. The discrepancies are discussed and a final agreement on the exchanged otoliths is at present achieved for all otoliths except ca. $2 \%$. A similar positive development is also seen for haddock age readings.

## Inadequacies in available software

The AFWG have found that the prediction program in use lack some important options. The stocks on the observation list require various methods to examine forecast options. The MFDP program would improve if F multiplier could be typed in for each year in the short term prediction.

Regarding the MFYPR program, useful improvements could be to have additional options for some parameters. These are:

- Scenario for different weight in catch at age for each year in the forecast.
- Scenario for different weight in stock at age for each year in the forecast.
- Scenario for different natural mortality in stock at age for each year in the forecast, due to e.g., cannibalism that may be predicted to vary from year to year.
- Scenario for different maturity at age for each year in the forecast.

As example, for doing the predictions of NeA cod in this year's assessment all the above listed parameter options were needed. It is preferred that the MFYPR program has the option to permit files to input these numbers in addition to the option to type the numbers from the keyboard.

During the AFWG-meeting, the survey-based assessments program SURBA (Needle 2003, 2004) was presented to the group, and useful runs were made with this program to explore the survey data and as a supplement to the adopted assessment procedures. However, when using SURBA some shortcomings were discovered. Below are listed some desired improvements/further developments.

The AFWG have used SURBA 2.1 version and SURBA version 2.2. Some fleets could be analyzed in SURBA 2.1 but give error handling problem in the newer version. An example is the single tuning series used in NeA cod assessment. Two tuning series could be analyzed in SURBA 2.2 and all four in the older version.

The following surveys and commercial CPUE data series was used for initial tuning runs by single fleets:

|  | Name | Place | Season | Age | Years |
| :--- | :--- | :--- | :--- | :--- | :--- |
| Fleet 17 | Russian bottom trawl surv. | Total area | Oct-Dec | $3-8$ | $1982-2003$ |
| Fleet 09 | Russian trawl CPUE | Total area | All year | $9-12$ | $1985-2003$ |
| Fleet 15 | Joint bottom trawl survey | Barents Sea | Feb-Mar | $3-8$ | $1981-2004$ |
| Fleet 16 | Joint acoustic survey | Barents Sea + Lofoten | Feb-Mar | 3-11 | 1985-2004 (Table A16) |

Running SURBA 2.2 with the shaded tuning fleets, give the error message:

FishFrame, an international web based database and data warehouse for biological information of commercial catches, was presented to the AFWG. The working group considered this software very useful for standardizing and quality assurance of the compilation of assessment input data. It will also provide important historical records of the assessment input data, the possibility to post-stratify data, to facilitate an easy access and overview to all data existing internationally, and to provide basis for additional analysis across countries and areas. The software including a dummy, but complete data set, should be made available to members of assessment working groups for further evaluation in order to do evaluations of FishFrame before eventually being adopted as a standard tool.

## Use of age- and length structured models in assessment (Fleksibest)

The development of a new assessment model for Northeast Arctic cod - Fleksibest - started at IMR, Bergen, in 1997. A description of the model is given in Frøysa et al. (2002). The model is age- and length-structured, and the biological processes growth, maturation, mortality, fishing and cannibalism are modelled as length-structured processes. Fleksibest is a forward simulation model based on the Gadget (formerly BORMICON, Stefánsson and Pálsson 1997, 1998, Anon., 2001, 2002) framework within which different formulations of biological processes can be tested and compared. Fleksibest is an extension of the type of age-structured assessment models where catches are modelled, sometimes termed CAGEAN or 'statistical catch at age analysis' (Fournier and Archibald, 1982, Deriso et al., 1985).

For NEA cod, Fleksibest has been used as a supplementary model to XSA for some years. Fleksibest is now a complete assessment model which provides the same kind of output (assessment, retrospective analysis, prognosis, diagnostics) as e.g. XSA. Although questions concerning choice of likelihood functions and appropriate aggregation level for model/data comparisons need further study, it may be time to give the results from Fleksibest more weight. The use of several assessment models for the same stock is increasingly common in several assessment working groups. A comprehensive analysis of the performance of XSA and Fleksibest should be presented to the 2005 AFWG meeting.

A project is currently underway to construct a multi-area, multi-species (cod, capelin, herring, minke whale) model for the Barents Sea using the Gadget modelling framework (see http://www.hafro.is/gadget), with the Fleksibest cod model as the starting point. This model will also build upon the MULTSPEC model (Bogstad et al., 1997). The ability to model the length-dependent interactions between species is critical to this work, which forms part of the new EU project BECAUSE. The move (with this model and elsewhere) towards biologically realistic multi-species models represents one possible route to a goal of more inclusive ecosystem-based management.

Adding length structure makes it easier to include biological realism by modelling growth, maturity, fecundity, recruitment, fishing mortality and natural mortality (e.g. cannibalism) as processes depending on fish length/weight, temperature, prey abundance and other factors. The current NEA cod Fleksibest model has been extended to contain four population groups (EggsandLarvae, 0-group, immature fish and mature fish) in order to model the closed life-cycle for cod as well as to include more biological realism. Results of extending the model down to age 1+ (without closed life-cycle) are discussed in this year's report. Results of the closed life-cycle model will be presented in a paper to the 2004 ICES ASC. With such an extension Fleksibest can be used to model the abundance of all age groups in the stock. Splitting immature and mature fish by sex in order to take sex differences in maturity, growth and natural mortality into account could further extend this approach. Such an extension will also make it possible to include fecundity/length/weight relationships in more appropriate way.

Age-length structured models such as Fleksibest were studied at the ICES Study Group on Age-Length Structured Assessment Models (SGASAM) in Bergen in June 2003 (ICES CM 2003/D:07). The meeting reviewed current status for age-length-structured and length-structured population models. Age-based models make an implicit assumption that processes are either age-dependant, or that age can be used as a proxy for the controlling factor (typically length). There is thus a need to consider length-structured or age-length-structured models where this assumption fails, or where age data is sparse or unreliable. Maturation, growth, cannibalism, predation and fishing mortalities were all presented as processes where age-structured modelling alone may prove insufficient. Examples of some attempts to resolve these issues with different model were presented, and the meeting compared age-length-structured models constructed for several different areas (Celtic Sea cod, whiting and blue whiting, NE Arctic cod, New Zealand snapper), and a lengthstructured model (Northern Shelf anglerfish). Length based modelling may also be useful in a situation where stock demographics (e.g. length-at-age, maturity-at-age) show changes over time. Such changes occur on an inter-annual basis, and may also show longer-term trends in response to fishing pressure or environmental changes.

A second meeting of SGASAM will be held in December 2004. In addition to reviewing ongoing developments in age-length-structured models, this meeting will examine incorporating process-based developments from the SGGROMAT meeting (ICES CM 2004/D:02) into age-length-structured models. The meeting also intends to examine comparisons between age-structured and age-length-structured models.

## ICES Quality Handbook

Following the guidelines as adopted by ACFM in October 2002, a stock specific template was filled out for all AFWG stocks, describing how the annual assessment calculations and projections are performed, as well as the biological stock dynamic, ecosystem aspect, and the fisheries relevant for fisheries management. These templates are presented as appendices to the working group report, and the report has been re-structured accordingly.

## Scientific Presentations

WD 1 (presented by J.E. Stiansen) describes the present oceanographic conditions, the role of zooplankton and some relations between climate and fish population parameters. A forecast for sea temperature in the Barents Sea is given.

WD2 (presented by B. Bogstad) gives a prognosis for the development of the Barents Sea capelin stock. The capelin stock is predicted to be 410 thousand tonnes at 1 January 2004 and 1420 thousand tonnes at 1 January 2005. The predictions are given with uncertainty. The prediction method has now been integrated into the capelin assessment software. It is planned to carry out a review of the prediction method before the capelin assessment meeting in October 2004.

WD3 (presented by B. Bogstad) describes the status of joint Norwegian-Russian work on evaluation of the proposed harvest control rule for Northeast Arctic cod. A biologically detailed population model for cod to be used in the evaluation is described. In this model, recruitment is modelled using a segmented regression approach, as well as a periodic term and a term including the mean weight of spawning fish. Growth and maturation is modelled as density dependent, and cod cannibalism can also be included. Assessment error and uncertainty in the stock/recruitment relationship is included. It is outlined, which harvest control rules should be explored and how they could be evaluated.

WD6 (presented by B. Bogstad) presents data on length, weight and growth at age for Northeast Arctic cod from surveys and commercial catches as well as data on cod stomach content. The condition factor has declined during the last year. Also, the amount of capelin in cod stomachs during the period January-March decreased by about $50 \%$ from 2003 to 2004 for most age groups, but did not reach historic low levels. The 1-year prediction of weight at age in the stock and in the catch made by AFWG last year was fairly accurate, with errors $<12 \%$ for all age groups 3-10 both for catch weights and stock weights. This document gives relevant information for predicting growth and maturation of cod.

WD9 (presented by Y. Kovalev) concludes that incorporation of the North-East Arctic cod cannibalism data into the VPA model improves the overall quality of its assessment but only when the entire time-series is considered (19852002). This is achieved by better consistency between survey abundance indices and VPA estimates for juvenile cod. In addition, variability in model estimates is also reduced according to retrospective analysis. The improvement is most apparent for estimates of recruitment at age 3 , which enhances confidence in predicting recruitment. However, when examining XSA diagnostics for the most recent years the improvement in the quality of the assessment is not quite so clear.

WD10 (presented by Y. Kovalev) demonstrates the low quality of predicting cod natural mortality caused by cannibalism with the method currently used by AFWG. Examining the feasible predictors of cod natural mortality from cannibalism, such as abundance/biomass of cannibals, prey abundance and capelin biomass, a parameter was chosen having the closest relationship with the mortality level - the biomass of cod spawning stock with minus 3 -year lag. In spite of the fact that the mechanism of the cod SSB influence on the level of natural mortality of young cod 3-4 years later is unclear, the strength of the statistical relationship between these quantities and some advantages compared to all other discussed methods of prognostication, may recommend this as the predictor for use at AFWG.

WD14 (presented by B. Bogstad) presents extensions and changes of the Fleksibest model from 2003 to 2004. Fleksibest has now been extended to cover age 1-12+ (previously $3-12+$ was used). Catch is now modelled by modelling effort, while previously it was modelled using fishing mortalities. Similarly, cod cannibalism is modelled as predation, not as mortality. The length selectivity is now described by logistic curves for all surveys.

WD16 (presented by A. Filin) describes results of simulation of year-to-year abundance dynamic of krill in the Barents Sea. The prognostic model is constructed on the basis of multiple linear regressions incorporating along with environmental factors (water temperature, NAO indices, sea level and ice coverage) and biomass of capelin. The model was tuned by data for the period 1977-2000. According to the model it is expected that in 2004-2005 euphausiid abundance will increase compared to 2003-2004 to above average (similar to 1987 and 1995), and subsequently decrease in 2005-2006 down to the level of 1989 and 1994.

WD17 (presented by A. Filin) describes results of monitoring of abundance and distribution of krill (euphausiids) in the Barents Sea, conducted by PINRO since 1952. From these monitoring data, it is seen that the abundance of euphausiids, as well as the peculiarities of their distribution, and that the specific composition is characterized by significant year-to-year dynamics, influence the fish feeding conditions. In autumn-winter 2003/04 the mean annual indices of euphausiid abundance was approximately $50 \%$ higher than the long-term mean. However, a reduction of these indices compared to the previous year was noticed. In the samples, Thysanoessa raschii prevailed and made up
$53 \%$. The relative abundance of $T$. inermis was $24 \%$, of Meganyctiphanes norvegica $-18 \%$ and of T. longicaudata $4 \%$.

WD 18 (presented by T. Bulgakova) proposes a simulation model, which is intended for testing and comparison of various management regimes for their feasibility and suitability for the NEA cod stock. The model is realized in the environment of EXCEL + VBA and works on a long retrospective period. This is a cod population model with recruitment depending on population fecundity index, on established inflow index of Atlantic waters, and on the SSB as cannibalism factor. The model comprises the management rule and stochastic modules, too. Three versions of harvest rule adopted by The Joint Russian-Norwegian Fisheries Commission are tested. The best of them (judged from the perspective to get high average multiannual catch and low risk probability to cross limit reference points) gives that the risk probability to fall below $\mathrm{B}_{\lim }$ is $5 \%$ during the simulation period, and the risk probability to come above the $\mathrm{F}_{\text {lim }}$ level is equal to $10 \%$. The increase of this allowable limit to $15 \%$ gave a zero probability of $\mathrm{SSB}<\mathrm{B}_{\mathrm{lim}}$ and of $\mathrm{F}>\mathrm{F}_{\text {lim }}$. Further increase of the percentage catch changes from year to year did not influence the cod population dynamics.

WD20 (presented by A. Filin) describes results of cod growth rate in the Barents Sea, performed by the STOCOBAR model. Model parameters were estimated by historical data for 1984-2002. The prognosis of cod growth rate is done for a three-year period, from 2003 to 2005. In the prognosis the forecasts of mean annual temperature in the Kola Section for 2003-2005 was used as input data, together with the prognosis of capelin biomass. According to model calculations, on the whole, the mean weight of fish is expected to be decreasing from 2003 to 2005 due to the predicted reduction in water temperature and capelin stock in the Barents Sea. The most pronounced reduction in growth rate is expected for fish from the younger age groups, 3-5 years. Significant changes of fish mean weight at the beginning of 2006, compared with 2005, are not predicted. As a whole, the mean weight of fish in 2004-2006 is expected to be lower than the long-term mean level (1984-2003).

WD 24 (presented by A. Aglen). The aim of this work is to establish a bycatch database for cod and other commercially important species in the shrimp fishery in the Barents Sea. The present WD estimates cod bycatch in numbers and weight by length groups on quarterly and yearly basis during 1983-2002 by tracing both in space and time the commercial shrimp catch and cod bycatch. Data available for this estimation include the official shrimp landing statistics, log-book data from shrimp trawlers, fishery surveillance data from the Directorate of Fisheries, and data from shrimp surveys and demersal fish surveys using Campelen shrimp trawl. The annual bycatch of young cod in the Norwegian shrimp fishery has been up to 60 mill. individuals, but has in recent years due to effective regulation measures decreased to $10-12$ mill. specimens. By adding similar bycatch estimates from other countries' shrimp fisheries, an implementation of cod bycatch as additional fishing mortality to cod stock assessment and management procedures should be considered.

WD 25 (presented by A. Aglen) a time series of total catch numbers at age of cod in the Norwegian trawl fishery was used to estimate partial Fs for this fleet. From effort data F per effort was calculated for the period 1977-2003. An increasing trend in F per effort was observed for the period after 1990 for age 7 and older. For age 5 and younger it has decreased again since 1993. These changes in F per effort make Catch per effort a biased indicator of stock size. (Calculations updated with the new vpa-assessment are presented in Figure 3.16 in the wg-report).WD 26 (presented by A. Aglen) a method for using catch at age analysis to calibrate survey estimates was presented. This is indicate to give more robust estimates of stock size than when using survey estimates to calibrate catch at age analysis (like xsa). The method was applied for the cod estimates in the Joint bottom trawl winter survey and compared to xsa-results from AFWG. Survey based predictions for 2004 were given.WD 27 (presented by V. Borisov) a retrospective analysis of percentage variations in the cod fishable stock in year "i" relative to year "i-1" for the period 1946-2002 was made. It was shown that in 35 cases in the period of 54 years the stock varied more than $\pm 10 \%$ from one year to the other; in 17 cases deviations exceeded $\pm 20 \%$, and in 6 cases they constituted from 30 to $61 \%$. TAC, which does not take into account fluctuations of the stock in neighboring years, can lead to overfishing in years of its decrease and also to underfishing in years of the stock growth. Adequacy of the relative yearly variation of TAC to the variation of the fishable stock should be included into the main elements of the fisheries management.

Two confidential reports (for 2002 and 2003) from the Norwegian Directorate of Fisheries, including spreadsheet examples of the estimation procedure, were circulated and presented by K. Nedreaas to the AFWG. Over the recent years there has been a growing concern that trans-shipping of fish from the Barents Sea may to some extent utilize loopholes in international control systems (and regulations) and thereby lead to trading of fish not counted against quotas. This topic was of high priority for the coordinated Norwegian-Russian activities on Fisheries Control in 2002, and was initiated by growing concern by Russia due to the sudden new development of trans-shipping fish in the open sea, and by Norway due to sudden decrease of landings in Norwegian harbours. It is therefore believed that the magnitude of the unreported landings increased sharply in 2002 and has continued since then. Various sources of information has been used to quantify the amount of cod landed, e.g., observations/inspections by the Norwegian coast guard (both transshipping vessels and fishing vessels), satellite tracking (VMS) of trans-shipping vessels and fishing vessels, detailed information on landings in Norway and supplementary and supporting information on landings in Russia, EU and

Canada. Also direct and indirect information from trans-shipping companies and information on quotas and catches by several fishing companies have been available. Out of ca. 400 active trawlers fishing cod in the Barents Sea, and systematically controlled by airplanes and coastguard, about 190 vessels got special attention.

## Time of Next Meeting

The Working Group proposes the dates of April $20-29,2005$ for it's next meeting.

The population dynamics of all commercial fish stocks are determined by fisheries effects and by environmental effects on growth, recruitment and natural mortality. The goal of this chapter is to describe the implications of interannual variation in the climate and trophic interactions for fish stocks in the Barents Sea ecosystem. Forecasts for the upcoming year are made for several variables. The consequences for growth, recruitment and natural mortality are also discussed.

### 1.1 Climate considerations in the Barents Sea

### 1.1.1 Temperature and ice conditions (Figures 1.1-1.2)

The Barents Sea is characterised by large year-to-year fluctuations in heat content and ice coverage caused by variations in the influx of Atlantic water from the Norwegian Sea. Temperatures in the Barents Sea have been relatively high during most of the 1990s, and with a continuous warm period from 1989-1995. During 1996-1997, the temperature was just below the long-term average before it turned warm again at the end of the decade, and has remained warm until present. Even though the whole decade was warm; it was only the third warmest decade in the $20^{\text {th }}$ century (Bochkov, 1982, Ingvaldsen et al. 2002).

In January 2003 the temperature was just above the long-term average in the whole Barents Sea, but then the temperature increased quickly until March when it was $0.7^{\circ} \mathrm{C}$ above the long-term mean. From April and the rest of the year, the temperature was $0.5^{\circ} \mathrm{C}$ above the long-term average. In January and March 2004 the temperature was still $0.5^{\circ} \mathrm{C}$ above the average. (Figs. 1.1 and 1.2, Stiansen et al., WD1).

The variability in the ice coverage is closely linked to the temperature of the inflowing Atlantic water. The ice has a relatively short response time on temperature changes in the ocean, but usually the sea ice distribution in the eastern Barents Sea responds a bit later than in the western part. 2003 had a negative ice index, which means more ice than average. This was very surprising since the sea temperature was high. There were two reasons for this. Firstly the really ice melt did not start before mid June, which is about one month later that usual. Secondly, the ice melt during summer was extremely low, most likely due to atmospheric forcing. In 2004 the ice coverage is expected to be the same as in 2003, but the ice index will depend on the ice melting in the summer 2004 (Stiansen et al., WD1).

### 1.1.2 Inflow of Atlantic water

Transport of Atlantic water to the Barents Sea has been measured since August 1997. The flow of Atlantic water is very variable. Most of the time there is a net inflow of Atlantic water to the Barents Sea, but in some periods large outflows are observed. High outflows occurred around April in 1998, 1999 and 2001. In 2000 there was strong outflow in January while in 2002 and 2003 strong outflow was observed in August/September. In the first half of 2003 the inflow was continuously high, which may explain the rapid temperature increase between January and March. The intensity of the flow was reduced during spring and summer. Results from a wind driven model shows similar results (Stiansen et al., WD1). Except for January, it is a good fit with the observations. The model results indicate that the variations in the local atmospheric pressure field may be important for the inflow of Atlantic water to the Barents Sea (Ådlandsvik and Loeng, 1991, Ingvaldsen et al., 2002, Stiansen et al., WD1).

### 1.1.3 Predicting Barents Sea temperature (Figure 1.2)

Prediction of Barents Sea temperature is complicated since the variation is governed by processes of both external and local origin that operate on different time scales (Stiansen et al, WD1). The volume flux and temperature of inflowing Atlantic water masses, as well as heat exchange with the atmosphere, is important in determining the temperature of the Barents Sea. Thus, both slowly moving advective propagation and rapid barotropic responses due to large-scale changes in air pressure must be considered. The major changes in Barents Sea climate take place during the winter months. The variability in the amount of heat flowing in with Atlantic water masses from the south is particularly high during this season. Furthermore, variability in low-pressure passages and cloud cover has a strong influence on the winter atmosphere-ocean heat exchange.

This seasonal difference is reflected in the merit of simple six-month forecasts (Ottersen et al., 2000) of Kola-section temperature (Bochkov, 1982) based on linear regression models. The tendency is that persistence across the spring and summer months are higher than for other seasons, allowing for reasonably reliable forecasts from spring until autumn. Data available until March 2004 allow for a six-month forecast until September 2004 (Stiansen et al., WD1). The predictions indicates that the temperatures in the southern Barents Sea will be close to average from April to June, followed by a warm ( $0.4^{\circ} \mathrm{C}$ above average) period from July to September (Fig. 1. 2).

### 1.1.4 Climatic effects on plankton (phyto,- zoo- and ichtyoplankton)

Variation in climate factors can have strong impact on the lower trophic levels in the ecosystem. Plankton is always subject to the surrounding physical environment. Limited self-motion compared to surrounding currents sets strong limitations on the ability to avoid or seek better climate condition. This is especially the case for climatic factors, which vary slowly and/or over large scale in space and time (e.g. temperature in the open waters). However, many plankton organisms have mechanisms allowing some kind of vertical motion and may thereby move to more profitable vertical layers. The influences on plankton from climatic factors with strong vertical gradients (e.g. turbulence and light) are therefore also dependent on the individual's behaviour. Different climatic factors may also affect individual plankton differently at different stages of its life cycle, and for fish also in nekton stages. Climate variation also affects the trophic interactions on different scales in time and space. The total effect of climate variation on plankton (and also nekton) is therefore a complicated matter.

The identification of which factors are most important in different processes is a major task in this field of research. For assessment purposes it is not possible to take all such factors and mechanisms into account. Still it is important to recognise that climate play a major effect on plankton.

A promising approach for implementing climate effects into the assessment is through the use of climate indicators. One such indicator is the North Atlantic Oscillation index (NAO), which is an overall indicator of the climate in the North Atlantic, Nordic Seas and the Barents Sea. Another climate indicator is the mean temperature in the Kola Section (Bochkov, 1982), which is a more local indicator of the temperature in the southern Barents Sea.

Based on such indicators the effect of climate on recruitment of cod has been estimated to account for as much as 50$70 \%$ of the variation in survival (AFWG 2003). Also, a high correlation is found between the NAO index and the zooplankton biomass in the Norwegian Sea the following year (Melle and Holst, 2001). Both these examples illustrate the necessity of taking climate conditions into account when considering the ecosystem.

## Conclusions section 1.1:

- 2003 was warmer than average. The temperature in the beginning of the year was just above average, followed by an strong increase in the spring and remaining warm for the rest of the year. In January and March 2004 the temperature was still $0.5^{\circ} \mathrm{C}$ above the average.
- The inflow of Atlantic water was high in the first half of the year, but with normal variation for the rest of 2003.
- The temperature in 2004 is expected to be normal for spring/early summer and warm for late summer/autumn in most of the Barents Sea.
- Climate conditions are predicted to be at the average long-term level, showing a slight trend towards warming. This will have a positive effect on zooplankton development and survival of fish at their early life stages.

### 1.2 Zooplankton

### 1.2.1 Sampling and abundance (Figure 1.3-1.4)

Zooplankton sampling on a regular basis IMR began in the Barents Sea in 1979, and since 1986 zooplankton abundance has been monitored at annual surveys during joint Norwegian/Russian 0-group and capelin surveys in August-October. In addition, the standard sections Bjørnøya-Fugløya and Vardø-N (since 1991) are covered on average 6 and 4 times a year, respectively. Regular macroplankton surveys have been conducted by PINRO in the Barents Sea since 1952. Surveys involve annual monitoring of the total abundance and distribution of euphausiids (krill) in autumn-winter trawlacoustic survey for demersal fishes. In 2002 PINRO also joined the collection of samples of zooplankton during August-October.

Plankton samples in August/October IMR were obtained by using WP2 (IMR, PINRO), MOCNESS (Multiple Opening Closing Net and Environmental Sensing System) plankton net (IMR) and Juday net (PINRO). In the PINRO macroplankton survey the trawl net was attached to the upper headline of the bottom trawl. During winter crustaceans are concentrated in the near-bottom layer and have no pronounced daily migrations and the consumption by fish is minimal. Therefore sampling of euphausiids during autumn-winter survey can be used to estimate year-to-year
dynamics of their abundance in the Barents Sea. Annually 200-300 samples of macroplankton are collected during these surveys. Species and size composition of the euphausiids in the samples are determined.

In autumn-winter most of the production has taken place and the zooplankton biomass can be expressed as the overwintering population of zooplankton. According to the data from August/October survey there was a marked increase in zooplankton biomass during the period 1991-1994. Though the biomass has decreased from 1994 to present, the average biomass values during 1995 to 2003 are still higher than in the 1988-1992 period. In 2003 the zooplankton biomass was at an average level, with a slight decrease from 2002 to 2003 (Stiansen et al., WD1).

Possible reasons for the large year-to-year variations are the differences in advective transport and predation pressure. Figure 1.3 shows the total biomass of zooplankton together with capelin stock size (million tonnes). There seems to be an inverse relationship between capelin stock size and zooplankton biomass, indicating capelin to exercise strong feedback control on the system through its predation pressure on zooplankton.

The results from long-term investigations of macroplankton in autumn-winter indicate that the abundance of euphausiids (Fig.1.4), as well as the distribution and specific composition, is affected by interannual dynamics. This leads to changes in the feeding conditions of fish (cod in particular). According to Ponomarenko (1973, 1984) interannual changes of euphausiid abundance determined the survival rate of cod yearlings. Adult cod feeding on euphausiids in summer influences seasonal dynamics of their fatness (Orlova et al., 1998). The role of euphausiids for cod feeding increases in the years when capelin stock is at a low level (Ponomarenko and Yaragina, 1990).

The Barents Sea community of euphausiids is represented by four abundant species: neritic shelf boreal Meganyctiphanes norvegica (M.Sars), oceanic arcto-boreal Thysanoessa longicaudata (Krøyer), neritic shelf arctoboreal Th. inermis (Krøyer) and neritic coastal arcto-boreal Th. raschii (M.Sars) (Drobysheva, 1994). According to the data from the long-term observations (Drobysheva, 1994; Drobysheva and Nesterova, 1996) Th. inermis and Th. raschii make up $80-98 \%$ of the total euphausiid abundance. Species ratio in the Barents Sea euphausiid community is characterized by year-to-year variability probably due to climatic variation as a main factor (Drobysheva, 1994).

In 2003/04, the samples of macroplankton were collected during cruises by three Russian and one Norwegian vessel (Zhukova et al., WD 17). In all, 373 macroplankton samples were collected.

In autumn-winter 2003/04 the mean annual indices of euphausiid abundance were about $50 \%$ higher than the long-term mean, both in the northwest and southern areas (Fig. 1.4). However, a reduction of these indices as compared to the previous year was noticed. In the samples Th. raschii prevailed and made up $53 \%$. The relative abundance of $T h$. inermis was $24 \%$, of Meganyctiphanes norvegica - $18 \%$ and of Thysanoessa longicaudata $-4 \%$.

### 1.2.2 Prediction of year-to-year dynamic of krill abundance (Figure 1.5)

The main reasons for the year-to-year variations in abundance of krill in the Barents Sea are the differences in advective transport and predation pressure. A multiple regression model for the abundance indices of euphausids in the Barents Sea is presented in Nikiforov (WD16). The model is based on capelin biomass along with environmental factors, and gives a two-year prognosis.

The model was tuned by data for the period 1977-2000. For the period from 1977 to 2000 the relationship between the mean water temperature in the Kola Section (averaged for three years with time lag of two years) and abundance indices of euphausids showed a correlation coefficient of 0.55 . Analysis of the relationship between euphausiid abundance indices and NAO indices showed that the closest inverse relationship ( $\mathrm{r}=-0.64$ ) was observed in August with a time lag of one year.

The analysis showed that when using synchronous series, the closest relationship between variations in the sea level and abundance indices of euphausiids occurred in April with a correlation coefficient of 0.43 . The relationship between ice coverage in the Barents Sea (time lag of one year) and euphausiid biomass was also fairly high ( $\mathrm{r}=0.42$ ).

Thus during 1977-2000, the effect of temperature and NAO indices on variations of euphausiid abundance was characterized by a negative relationship, while the sea level and ice coverage displayed positive relationship.

A trial run using dependent material as well as independent data for the period 2001-2003 showed that the model described up to $73 \%$ of year-to-year variability of abundance indices of euphausiids in the southern Barents Sea (Fig. 1.5). According to the model it is expected that in 2004-2005 euphausiid abundance will increase to above average,
compared to 2003-2004 (similar to 1987 and 1995) Further, it is expected to be a decrease in 2005-2006 down to the level of 1989 and 1994.

## Conclusion section 1.2:

- An overwintering zooplankton biomass moderately above the average in 2003/2004 will create the basis for an average zooplankton production in 2004. This will give average feeding conditions for capelin and other pelagic fish and juvenile demersal species in the Barents Sea in 2004.

### 1.3 Trophic interactions

### 1.3.1 Predicting capelin biomass (Tables 1.1-1.2)

Capelin is the most important prey species for Northeast Arctic cod, and the development of the capelin stock may have a strong effect on growth and maturation of cod, as well as cod cannibalism.

The biomass of capelin (1+) decreased from 2.2 million tonnes in 2002 to 0.5 million tonnes in 2003 (Anon., 2003). This is considerably lower than the prediction for 2003 made by AFWG last year ( 2.0 million tonnes). The prediction method used in Anon. (2003), which is essentially the same as previously used, predicts the biomass of 1+ capelin in October 2004 to be 1.71 million tonnes ( $90 \%$ confidence interval: $0.86-2.87$ ). Of this 0.13 million tonnes ( $90 \%$ confidence interval: 0.001-0.439) are predicted to be mature capelin (Gjøsæter and Bogstad, WD2). The stock history for capelin from 1984 onwards is given in Table 1.1 together with the estimated biomass of capelin removed from the stock by natural mortality.

A 1-year prognosis has been presented to AFWG since 1999. A review of the prognoses made during this period is given in Table 1.2. The prognoses seem to be overestimates in most cases. The prediction methodology is still under development. Before the assessment meeting for Barents Sea capelin in October 2004, it is planned to carry out an analysis of the how the current prediction method performs on historical data.

### 1.3.2 Predation by cod (Table 1.3-1.6, Figure 1.6)

The consumption by cod of various prey species for the period 1984-2003 is given in Table 1.3, using the same method as described by Bogstad and Mehl (1997). Dolgov (WD 4, Table 1.4) also calculated the consumption by cod based on the same data, using a somewhat different methodology.

As usual, capelin was the most important prey for cod. Table 1.3 shows that the proportion of capelin in the diet of cod was about $50 \%$ both in 2002 and 2003, but the total consumption of capelin by cod increased from 2002 to 2003 due to an increase of the cod stock. These results are somewhat surprising in view of the decline in the capelin stock. The consumption by cod of herring, polar cod, haddock, shrimp, krill and amphipods) increased from 2002 to 2003, while the consumption of cod and blue whiting decreased from 2002 to 2003. The calculation of consumption of cod and haddock by cod using this method are used in the assessment of cod and haddock (Sections 3 and 4).

The consumption by prey species from the two calculation methods for 2003 and the changes from 2002 to 2003 are fairly similar. The main difference is that the calculations in Table 1.3 give an increase in the consumption of capelin from 2002 to 2003, while the calculations in Table 1.4 show a decrease. Also, the consumption of haddock by cod in 2003 given in Table 1.4 is much higher than the figures given in Table 1.3, and there are notable differences in the time series of number at age of cod and haddock consumed by cod. It should be noted that the calculations in Table 1.3 are based on the number at age of cod from the VPA given in this year's report, while the calculations in Table 1.4 are based on the VPA from the 2003 AFWG meeting. The difference between the methodologies is less than shown in last year's report, as the same stomach evacuation rate model is now used in both methods. However, there are still inconsistencies between the methods, in that the consumption per cod is fairly equal for all age groups (Table 1.5 and 1.6) while the total consumption differs substantially for some prey items (Table 1.3 and 1.4). Steps will be taken to investigate possible reasons for these differences and reconcile them.

Preliminary data from the Joint winter survey in 2004 show that the amount of capelin in cod stomachs during JanuaryMarch 2004 was about $50 \%$ of the level observed during the same period in 2003, but still well above the lowest level observed (Bogstad, WD6).

The annual consumption for each age group of cod (kg/year), based on the consumption calculations shown in Tables 1.3 and 1.4 are given in Tables 1.5 and 1.6, respectively. Table 1.5 shows that the consumption per cod increased
somewhat from 2002 to 2003 for most age groups, while Table 1.6 shows a slight decrease for most age groups. Both tables show that the consumption per cod in 2003 is close to the long-term average. The discrepancies in consumption per cod by age group are fairly small.

The consumption estimates in Tables 1.3 and 1.4 do not include the consumption by mature cod in the period when it is outside the Barents Sea (assumed to be 3 months during the first half of the year). During this period it may consume significant amounts of adult herring (Bogstad and Mehl 1997).

Johansen et al. (2004) describe a new method for calculating the consumption by cod, and applies this to calculate the consumption of herring by cod in the period 1992-1997. Their consumption estimates are comparable to the estimates given in Table 1.3, except for 1994, when they obtained a much higher estimate ( 494 vs. 147 thousand tonnes).

As in previous years, the consumption of cod and haddock by cod (Section 3 and 4), which is taken into account in the assessment of these species, was calculated using the method described by Bogstad and Mehl (1997).

The calculations of annual cod consumption of capelin, krill and young cod in the Barents Sea in 1984-2005 using the STOCOBAR model (Filin, WD20) are presented in Figure 1.6. In general there is a good agreement between the model calculations and calculations based on methods described by Bogstad and Mehl (1997) and Dolgov (WD 4, Table 1.4), except for 1992. This year the capelin stock was large, and according to the STOCOBAR model the consumption by cod must also have been high. Concerning cod consumption of their juveniles, the results from STOCOBAR exceed the figures obtained by Bogstad and Dolgov for 1984-1996, but show good agreement for the recent years. Model results of consumption of krill by cod were in general between calculations by Bogstad and Dolgov. A comparison of the STOCOBAR model with results from Bogstad and Dolgov is shown in Figure 1.6.

### 1.3.3 Predation by other fish species

Dolgov et al. (WD 11, AFWG 2002) investigated the diet of blue whiting in the Barents Sea in the period 1998-2001. They concluded that predation by blue whiting will not have a significant impact on the recruitment of cod, haddock and redfish. However, food competition between blue whiting and juveniles of other commercial fish stocks due to blue whiting grazing zooplankton in the areas of larval drift may occur. The diet of saithe in the period 1998-2001 was investigated by Dolgov (WD12, AFWG 2002). The diet of saithe $>40 \mathrm{~cm}$ is dominated by capelin, with herring and euphausiids being next in order of importance. In some areas there are significant amounts of blue whiting and haddock juveniles. For saithe $<40 \mathrm{~cm}$, the diet is dominated by euphausiids.

### 1.3.4 Predation by mammals (Table 1.7)

The consumption by minke whale (Folkow et al. 2000) and by harp seal (Nilssen et al. 2000) is given in Table 1.7. These consumption estimates are based on stock size estimates of 85000 minke whales in the Barents Sea and Norwegian coastal waters (Schweder et al., 1997) and of 2223000 harp seals in the Barents Sea (ICES 1999/ACFM:7). The consumption by harp seal is calculated both for situations with high and low capelin stock, while the consumption by minke whale is calculated for a situation with a high herring stock and a low capelin stock. Food consumption by harp seals and minke whales combined is at about the same level as the food consumption by cod, and the predation by these two species needs to be considered when calculating the mortality of capelin and young herring in the Barents Sea.

In the period 1992-1999, the mean annual consumption of immature herring by minke whales in the southern Barents Sea varied considerably ( $640 \mathrm{t}-118000 \mathrm{t}$ ) (Lindstrøm et al. 2002). The major part of the consumed herring belonged to the strong 1991 and 1992 year classes and there was a substantial reduction in the dietary importance of herring to whales after 1995, when a major part of both the 1991 and 1992 year classes migrated out of the Barents Sea. In 19921997, minke whales may have consumed 230000 t and 74000 t , corresponding to 14.6 billion and 2.8 billion individuals of the herring year classes of 1991 and 1992, respectively. The dietary importance of herring to whales appeared to increase in a non-linear relation with herring abundance.

## Conclusions section 1.3:

- The capelin biomass is expected to increase from 2003 to 2004, but the mature stock is expected to remain at a low level also in 2004.
- The consumption of capelin by cod increased from 2002 to 2003, according to Norwegian consumption calculations, but decreased according to the Russian calculations.
- The consumption of herring, polar cod, haddock, shrimp, krill and amphipods by cod increased from 2002 to 2003, while the consumption of blue whiting and cod decreased from 2002 to 2003. The consumption per cod is close to the long-term average.

### 1.4 Ecosystem data for potential use in the stock assessment and projections

### 1.4.1 Recruitment

### 1.4.1.1 Recruitment models (Table 1.8, Figure 1.7)

Predictions of the recruitment in fish stocks are essential for future harvesting of the fish stocks. Traditionally prediction methods have not included effects of climate variability. Multiple linear regression models can be used to incorporate both climate and fish parameters. Especially interesting are the cases where there exists a time lag between the predictor and response variables as this gives the opportunity to make a prediction.

Models (Stiansen et al., WD1), based on climate and fish stock parameters, for prediction of recruitment have been given for the 0 -group index (with 2 -year prognoses) and the number of three-year-old fish for North East Arctic Cod (with 3-year prognoses), for the number of one-year-old fish for Barents Sea capelin (with 1-year prognoses) and for the number of three-year old fish for Norwegian spring spawning herring (with 3-year prognoses) (Tab. 1.8). The models are encouraging, and the models might at present prove useful as background information for stock assessment, and may in the future be incorporated as recruitment models in the assessments.

Borisov and Bulgakova (2002) give another approach. A new stock-recruitment model is developed, which includes an index of Atlantic inflow (Bulgakova, 2003). This model together with a new management scheme, are incorporated in a simulation model for NEA cod. This simulation model allows for a three-year prediction of recruits of age 3 (Tab. 1.8) up to 2006 (WD 15).

Models by Titov (1999, 2001, WD8) estimate the recruitment of the Barents Sea capelin at age 1 and NEA cod at age 3, with prognostic probabilities of 1-2 and 1-4 years respectively. The model uses aggregated ecosystem indices, which incorporates both biological and climate parameters (further details can be found in Titov, WD8). The predictions for cod at age 3 are shown in Table 1.8 for comparison with the other models.

The recruitment estimates from XSA/RCT3 and from Fleksibest are also given in Tab. 1.8. The various models are compared graphically in Fig. 1.7. There is relative good correspondence between the various methods concerning recruitment in 2005 and 2006, while there are large discrepancies for 2004 It was decided to use the 'traditional' RCT3 estimates in the predictions of cod recruitment.

## Conclusions sections 1.4.1:

- The 0-group index of NEA cod is expected to increase to a medium strong level in 2004 and 2005.
- Six out of eight recruitment models give a prognosis for the number of recruits (age 3) in 2004 below average. For 2005 and 2006 the corresponding fractions are three out of six and three out of four, which may indicate that the prospects for recruitment in near future is average or below average. The RCT3 method was used to predict recruitment also in this year's assessment.
- The number of recruits (age 1) of Barents Sea capelin is expected to be at a medium high level in 2004.

### 1.4.2 Growth

### 1.4.2.1 Prediction of NEA cod growth rate (Table 1.9)

The Northeast arctic cod is characterized by significant year-to-year variations in the growth rate. In different years the mean weight of fish at the same age may differ 2-3 times. This should be taken into consideration when forecasting stock dynamics. Among the factors influencing cod growth are water temperature, food supply and cod population abundance. A prognosis of cod growth in the Barents Sea was performed by the STOCOBAR model (Filin, WD20). The model is used to calculate mean weight of fish at age 2-10 in the beginning of the year based on input data on food supply, temperature and size of cod abundance.

Model parameters were estimated based on historical data for 1984-2002, using stomach data from the RussianNorwegian database, mean annual temperature data in the Kola Section, estimated biomass of capelin and data on abundance and mean weight-at-age from the AFWG 2003 assessment.

The forecast of cod growth rate was made for 2003-2005 with 2002 taken as a starting year. Observed data from the start of 2002 were used in the forecast of mean weight at age. The mean weight of a cod aged 1 for 2004 and 2005 was calculated as a mean over the 3 previous years. In the prognosis the forecasts of mean annual temperature in the Kola Section for 2004-2005 was used as input data, together with the prognosis of capelin biomass in 2004 and 2005 (Gjøsæter and Bogstad, WD2).

The results of forecasting the growth rate of cod aged 3-8 are presented in Table 1.9. The modeled weight of fish at the beginning of 2003 is shown as compared to the actual data. The greatest discrepancy of modeled and actual fish individual weight values was noticed for 3 and 4 -year-old age groups. The modeled weight at age in the beginning of 2004 is slightly below the observed values for age groups 2-9.

In general, model calculations showed that the mean weight of fish is expected to be decreasing from 2003 to 2005, due to the predicted reduction in water temperature and capelin stock in the Barents Sea. The most pronounced reduction in growth rate is expected for fish from the younger age groups (age 3-5). For 2004-2006 the mean weight of fish is in general expected to be lower than the long-term mean average (1984-2003).

### 1.4.2.2 Effects of capelin and temperature on maturation of cod (Table 1.10, Figure 1.8-1.11)

The decrease in capelin stock biomass potentially impacts the maturation dynamics of Northeast Arctic cod by delaying the onset of maturation and/or increasing the incidence of skipped spawning. From the perspective of incorporating this knowledge into a predictive model which could be used in the assessment there must be some degree of similarity between the data that are produced by the assessment and the variables included in the model. One approach to investigating the links between food availability and maturation is to examine the correlation between weight- and maturity-at-age. Bivariate plots of these two variables for Northeast Arctic cod show that there is a clear distinction between the 1946-1979 and 1985-2001 time periods (Fig. 1.8). In the earlier time period cod were maturing more slowly for their weight-at-age. Norwegian and Russian estimates of weight- and maturity-at-age (i.e., the time series that are used to estimate the stock weight- and maturity-at-age) confirm that the two time periods are distinct. Because the distinction is evident in two independent databases there is little likelihood that it is a result of changes in data quality.

Weight- and maturity-at-age data in Figure 1.8 were converted to weight- and maturity-at-length using age/length keys described by Marshall et al. (in press). The relationship between weight- and length-at-age shows that for a given length weight-at-length is positively correlated with proportion mature-at-length for the 1985-2001 time period (Fig. 1.9). Furthermore, the recent time period has distinctly higher values of weight-at-length than the earlier time period. This indicates that fish mature earlier when they are heavier at length. These results are consistent with bioenergetic studies that show feeding rates impact the onset of cod maturation (Lehmann et al. 1991) and with field observations showing condition to have a significant effect on the proportion of mature cod (Marteinsdottir and Begg 2002).

Estimates of weight-at-length were multiplied by the Russian liver condition index at length (Yaragina and Marshall 2000) to derive estimates of liver weight in grams for cod at a standard length (see Marshall et al. in press for details of this calculation). This analysis indicated that for the 1985-2001 there is a consistently significant, positive relationship between liver weight and proportion mature (Fig. 1.10). For two length classes (midpoints 72.5 and 82.5 cm ) there are significant correlations between liver weight and proportion mature for the earlier time period as well. This result confirms that the magnitude of stored energy is positively correlated with proportion mature. Furthermore, these derived estimates of liver weight are, positively correlated with capelin stock biomass over the entire 1946-2001 time period (Fig. 1.11) $\left(\mathrm{n}=54, \mathrm{r}^{2}=0.44, \mathrm{p}<0.001\right.$ Marshall et al. in press). Thus, capelin stock biomass impacts cod maturation by influencing the magnitude of stored energy reserves.

To investigate whether temperature had any effect on the relationship between liver weights and proportion mature average temperature values for July through December were calculated using the Kola section time series. The mean temperature of the last six months in the preceding year was did not explain a significant amount of variability in the proportion mature-at-length in models that use liver weight to represent the bioenergetic status (Table 1.10). Thus, variability in temperature does not appear to impact the proportion mature of cod.

This analysis also serves to illustrate the usefulness of converting age-based assessment data to length-based. There was no relationship between weight-at-age and maturity-at-age for the 1985-2001 time period (Fig. 1.8) but when converted to length the data showed statistically significant relationships between weight and proportion mature (Fig. 1.9) as well
as between liver weight and proportion mature (Fig. 1.10). Thus, age/length keys are an essential requirement for modelling the maturity dynamics of cod for projection purposes. Results obtained using age-based data are highly likely to obscure important trends. A modelling approach to implement this knowledge in the assessment could be developed intersessionally.

Conclusions section 1.4.2:

- Mean weight of cod is expected to decrease from 2003 to 2005 . The most pronounced reduction in growth rate is expected for fish from the younger age groups (age 3-5). For 2004-2006 the mean weight of fish is in general expected to be lower than the long-term mean average (1984-2003).
- Cod weight-at-length is uncorrelated with capelin stock biomass, whereas liver weights show a positive correlation. Thus, assessing the degree of inter-annual variation in condition requires routine monitoring of liver weights, such as has been done by PINRO since 1927.
- There is a significant, positive relationship between liver weight and proportion mature (for the period 19852001). Thus, the magnitude of stored energy is positively correlated with proportion mature.
- For a given length weight-at-length is positively correlated with proportion mature-at-length for the 1985-2001 time period. This was illustrated by converting age-based assessment data to length-based, age/length keys are an essential requirement for modelling the maturity dynamics of cod for projection purposes.

### 1.4.3 Natural mortality

### 1.4.3.1 Cannibalism mortality for cod (Table 1.11)

An alternative approach for prediction of NEA cod cannibalism based on the linear relationship between the natural mortality of cod at ages 3-5 and the biomass of cod spawning stock with minus 3-year lag was proposed (WD10). Using this approach the predicted natural mortality coefficient for cod including cannibalism seems to be higher compared to "the standard" prediction sec. 3.3.8

For age 3 the level of natural mortality tend to increase from 0.3 in 2004 to 0.54 in 2007 and for age 4 from 0.23 to 0.31 . Values for the years 2004 to 2006 are given in the text table below:

|  | M2 age 3 | M2 age 4 |
| :---: | :---: | :---: |
|  | by regression |  |
| 2004 | 0.30 | 0.23 |
| 2005 | 0.40 | 0.26 |
| 2006 | 0.45 | 0.28 |
| values used in assessment |  |  |
| $2004-$ | 0.2655 | 0.2134 |

Because the mechanism of the cod SSB influence on the level of own young natural mortality in 3-4 years is unclear the WG decided not to use this approach for prediction before it will be further tested.

Table 1.11 shows the proportion of cod in the cod diet, by predator age and year. This proportion increases by predator age.

Table 1.1. Capelin stock history from 1984 and prognosis for capelin biomass in 2004. M output biomass is the estimated biomass of the capelin removed from the stock by natural mortality.

Table 1.7. Consumption by minke whale and harp seal (thousand tonnes). The figures for minke whales are based on data from 1992-1995, while the figures for harp seals are based on data for 1990-1996.

| Prey | Minke whale consumption | Harp seal consumption <br> (low capelin stock) | Harp seal consumption <br> (high capelin stock) |
| :--- | :---: | :---: | :---: |
| Capelin | 142 | 23 | 812 |
| Herring | 633 | 394 | 213 |
| Cod | 256 | 298 | 101 |
| Haddock | 128 | 47 | 1 |
| Krill | 602 | 550 | 605 |
| Amphipods | 0 | 304 | $313^{2}$ |
| Shrimp | 0 | 1 | 1 |
| Polar cod | 1 | 880 | 608 |
| Other fish | 55 | 622 | 406 |
| Other crustaceans | 0 | 356 | 312 |
| Total | 1817 | 3491 | 3371 |

[^0]Table 1.8. Overview of recruitment models prognoses together with the 2004 assessment estimates. Models A-C is from WD1, model D from WD8, model E from WD15 and model F from WD1. The models G and H are similar to model D, with the exception that for the survey index for age 2 and age 3 are used instead of age 1. The last rows show the NEA cod recruitment estimates from the assessments by XSA in 2003 and 2004 and for Fleksibest in 2004 (Section 3.5.2 and 3.10.4). The given month in the fifth column indicate when the prognoses can be extended for another year.

|  | Species | Variable | Prognoses year | Prognoses available | $\begin{aligned} & \hline 2004 \\ & \text { Prognoses } \\ & \hline \end{aligned}$ | $\begin{aligned} & \hline 2005 \\ & \text { Prognoses } \\ & \hline \end{aligned}$ | $\begin{aligned} & \hline 2006 \\ & \text { Prognoses } \\ & \hline \end{aligned}$ |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| A | NEA cod | $\begin{gathered} \text { 0-group, } \\ \log (\text { age } 0) \end{gathered}$ | 2 | November | 1.47 | 1.65 | X |
| B | Barents Sea capelin | Recruits <br> (age 1) | 1 | November | $315 * 10^{9}$ | X | X |
| C | Norwegian spring spawning herring | Recruits <br> (age 3) | 3 | November | $3.0 * 10^{9}$ | $9.0 * 10^{9}$ | $12.1 * 10^{9}$ |
| D | NEA cod | Recruits (age 3) | 4 | Before assessment | $384 * 10^{6}$ | $626 * 10^{6}$ | $494 * 10^{6}$ |
| E | NEA cod | Recruits <br> (age 3) | 3 | Before assessment | $667 * 10^{6}$ | $565 * 10^{6}$ | $689 * 10^{6}$ |
| F | NEA cod | Recruits <br> (age 3) | $2\left(3^{1}\right)$ | November (March ${ }^{1}$ ) | $679 * 10^{6}$ | $747 * 10^{6}$ | $459 * 10^{6}$ |
| G | NEA cod | Recruits <br> (age 3) | $1\left(2^{1}\right)$ | November (March ${ }^{1}$ ) | $539 * 10^{6}$ | $486 * 10^{6}{ }^{1}$ | X |
| H | NEA cod | Recruits <br> (age 3) | $0\left(1^{1}\right)$ | November (March ${ }^{1}$ ) | $553 * 10^{6}{ }^{1}$ | X | X |
| XSA/RCT3 <br> Assessment 2003 | NEA cod | Recruits <br> (age 3) | 3 | At assessment | $308 * 10^{6}$ | $664 * 10^{6}$ | X |
| XSA/RCT3 <br> Assessment 2004 | NEA cod | Recruits <br> (age 3) | 3 | At assessment | $276 * 10^{6}$ | $604 * 10^{6}$ | $455 * 10^{6}$ |
| Fleksibest Assessment 2004 | NEA cod | Recruits <br> (age 3) | 1 | At assessment | $131 * 10^{6}$ | X | X |

${ }^{1}$ For the prognosis of NEA cod recruitment in model F-G a prognosis of mature capelin biomass for 2004 (129 000 tonnes) is used (Section 1.3.1), thereby allowing for an additional year.

Table 1.9 Prognoses of mean weight at age of NEA cod at the beginning of the year by the STOCOBAR model, together with the observations in 2003 and 2004.

### 2.1 Status of the Fisheries

### 2.1.1 Landings prior to 2003 (Tables 2.9, 2.19, Figure 2.2)

The catches of Norwegian Coastal cod (NCC) have been calculated back to 1984. During this period the catches have been between 25,000 and $75,000 \mathrm{t}$. The estimated landings of NCC in 2002 reported to the Working Group is $40,994 \mathrm{t}$ and the provisional figure for 2003 is $34,635 \mathrm{t}$ (Tables 2.9, 2.19, Figure 2.2). The landings in 2003 decreased compared with 2002. However, the landings were higher than expected. In the Lofoten area and in the southern part (statistical area 06 and 07) the landings were at the same level as in 2002 while the landings in the northernmost region decreased. In this region the availability of Northeast Arctic cod was high on the fishing banks near the coast and a major part of the smaller vessels quotas consisted therefore of Northeast Arctic cod. The catches inside the 12 n.mile zone was separated to type of cod by the structure of the otoliths (ref. Quality Control Handbook, Coastal cod). A total of 12,437 were collected from the commercial catches (Table 2.1.A) separated into quarter of catch and fishing gear. Approximately $25 \%$ of the otoliths were classified as coastal cod.

### 2.1.2 Expected landings in 2004 (Figure 2.5)

The quota for Norwegian coastal cod was reduced from $40,000 \mathrm{t}$. in 2003 to 20,000 t. in 2004. To achieve a reduction in landings of coastal cod new technical regulations were adopted in 2004 in Norway. In the new regulations lines are drawn along the shore to close several fjords for direct cod fishing with vessels larger than 15 meter (Figure 2.5). These regulations are supposed to turn the traditional coastal fishery over from catching coastal cod in the fjords to catch more cod outside the fjords where the proportion of Northeast Arctic cod is higher. However, these new regulations did not become operative before the beginning of May. At this time many of the small coastal vessels had already fished most of their cod quotas and the new regulations might therefore only to some extent influence the landings of coastal cod.

During winter/spring the amount of Northeast Arctic cod at spawning migration near the Norwegian coast was large (Mehl et al., WD 12 ) and hence the accessibility for the fishermen, and most of the smaller coastal vessel quotas were therefore taken before May. The amount of Northeast Arctic cod spawning inside the Lofoten area was small, and hence a major part of the landings in this region is expected to consist of coastal cod. I addition, the remaining part of the quotas for the coastal vessels that will be taken after May will consists of a high proportion coastal cod. This makes it difficult to estimate the landings in 2004 accurate. The working group therefore assume a status quo fishing mortality in 2004, which will result in landings of 21,847 tonnes using the same exploitation pattern as in the period 2001-2003, scaled to the 2003 level.

### 2.2 Status of Research

### 2.2.1 Survey results (Tables 2.1.B, 2.2, 2.3, 2.4, 2.5, 2.6, 2.7)

A new trawl-acoustic survey was conducted along the Norwegian coast from Varanger to Stadt in October-November 2003 using RV Jan Mayen and RV Johan Hjort. This is a combined survey covering the distribution of coastal cod and Northeast Arctic saithe and replaces two other surveys (saithe survey and coastal survey). In 2003 the survey covered a larger area than the coastal surveys in 1995-2002. However, the survey indices are calculated the same way as previous years using the same covering area as for previous surveys. The survey indices will not be recalculated before the time series from the new survey is extended.

The trawl-acoustic coastal survey in 2003 estimated a total survey biomass of NCC of about $32,000 \mathrm{t}$ ( 19 million fish) from Varanger to Stadt at $62^{\circ} \mathrm{N}$ (Tables 2.1.B, 2.2, 2.7). The spawning biomass accounted for $16,000 \mathrm{t}$ ( 4 million fish) of the total (Tables 2.3, 2.4). More than eighty percent of the total coastal biomass was distributed from the Russian border to $67^{\circ} \mathrm{N}$ and less than $20 \%$ south of $67^{\circ} \mathrm{N}$ (Norwegian statistical areas 06 and 07 ). The bulk of the biomass was comprised of ages 3-8 (Table 2.2).

The data indicated a higher proportion of NCC in the fjords and to the south compared with the northern and outer areas. In the Norwegian statistical areas 06 and 07 (south of $67^{\circ} \mathrm{N}$ ) nearly all otoliths collected were of the NCC type, which is similar to the results of the 1995-2002 surveys.

The numbers of NCC per age groups from all the coastal surveys is given in Table 2.7. The total numbers decreased in 2003 compared with the 2002 survey. For age groups 2-5 the biomass and numbers decreased considerably from 2002 to 2003. The numbers decreased most in the southernmost region (area 07) (Table 2.1.B).

The Norwegian 2004 coastal survey (October-November) will be conducted in a similar way as the previous one (2003) to further extend the time series for NCC over its distribution area.

### 2.2.2 Age reading and stock separation

Age readings of the cod both from the surveys and from the catches, are done the same way as for the NEAC. A total of 3133 cod otoliths were sampled during the 2003 survey, and separated into NCC type (2593) and NEAC (540). The precision and accuracy of the separation method is under investigation by comparison of different otolith readers and results from genetic investigation of cod. Preliminary results indicate more than $95 \%$ accuracy in the estimates.

As in previous years, NCC was found throughout the survey area. The 2003 survey data shows the same pattern as the 1995-2002 surveys. The proportion of the NCC increases going from north to south along the Norwegian coast. The NCC type otoliths dominate south of $67^{\circ} \mathrm{N}$ (Norwegian statistical areas 06 and 07 ). Although the proportion is lower, there is significant biomass of NCC north of $67^{\circ} \mathrm{N}$. It must be emphasised that the Norwegian coastal surveys have been conducted in August-November, and there may be more NEAC in the southern area at other times of the year, especially during the spawning season in the wintertime.

### 2.2.3 Weight-at-age (Tables 2,5 2.11)

There is a general tendency for cod to have higher weight-at-age when caught further south along the coast (Tables 2.5, 2.11). The same tendency was found for the surveys in 1995-2002. The number of cod estimated in the southernmost area decreased substantially from 2002 to 2003 . This is probably the main reason why the weight-at-age (weighted average) from the trawl-acoustic survey in 2003 was lower for all ages (except for age 8) compared with the 2002 survey. The difference in weight at age between 2003 and 2002 increased with age. The weight-at-age for NCC is however, well above the present level for NEAC.

### 2.2.4 Maturity-at-age (Tables 2.6, 2.12)

The maturity-at-age is estimated from the data collected at the Norwegian coastal survey. The age at $50 \%$ maturity $\left(\mathrm{M}_{50}\right)$ for the NCC was estimated to be close to 6 year on average for the surveyed area in 2003 (Tables 2.6, 2.12). There are some variations between the different areas. The 2003 data show that the average $\mathrm{M}_{50}$ is at a higher age as that found in the 2002 survey. The main reason for the higher age at maturation might be the substantial reduction in number of cod estimated in the southern area, where cod is growing faster and reaches $\mathrm{M}_{50}$ at younger age. However, the survey is conducted in the period October/November. In this period the maturity ogive can be difficult to define exactly and might influence the estimation of maturity-at-age and hence the estimation of SSB. In addition, the average $\mathrm{M}_{50}$ for the NEAC in 2003 is close to 7 years.

### 2.3 Data Used in the Assessment

### 2.3.1 Catch-at-age (Table 2.9)

The catches of coastal cod are calculated splitting the total catches of cod caught inside the 12 n.mile zone into coastal cod and Northeast Arctic cod based on samples from commercial catches. The proportion coastal cod is estimated by inspection of the otoliths (see chapter 2.2.2).

The catch-at-age (2-10+) for the period 1984-2003 is given in Table 2.9. The exploitation pattern in 2003 was similar to that observed last year.

### 2.3.2 Weight-at-age (Table 2.10, 2.11)

The weight-at-age in the stock, used in the assessment, is obtained from the Norwegian coastal survey (Table 2.11). The survey is covering the distribution area of the stock. Weight-at-age from this survey is therefore assumed to reflect the weight-at-age in the stock. Weight-at-age in 2003 was slightly lower for all ages (except for age 8 ) compared with 2002 (see 2.2.3). The weight-at-age in the catch is given in Table 2.10. Weight at age in the catch increased from 2002 to 2003 caused by a relative higher proportion cod caught in the southernmost area where weight at age is somewhat higher compared with further north.

### 2.3.3 Natural mortality

A fixed natural mortality of 0.2 was used.

### 2.3.4 Maturity-at-age (Tables 2.6, 2.12)

The maturity ogive data in 2003 is obtained from the Norwegian coastal survey (Tables 2.6, 2.12). The proportion mature at age has decreased the latest years for ages 3-6 (ref. chapter 2.2.4) (Table 2.12).

### 2.3.5 Tuning data (Table 2.7)

In previous assessments (until 2002) the acoustic indices (age 2-10+) from the Norwegian coastal survey conducted late autumn (1995-2001) have been used in the tuning (Table 2.7). ACFM proposed in 2002 to exclude age group 9 from the tuning fleet due to high S.E. $(\log q)$ for this age group. The S.E. $(\log q)$ was slightly lower for several ages when excluding age 9 , and the WG in 2003 therefore decided to exclude it in the tuning in last year's assessment. The same age groups are used in this year's assessment.

### 2.3.6 Prediction data (Tables 2.20, 2.21, 2.22)

The input data to the short-term prediction with management option table (2004-2006) are given in Table 2.21. Weight at age in the stock has decreased and the age-at-maturation $\left(\mathrm{M}_{50}\right)$ increased because the proportion of cod in southernmost area has decreased the latest years. Cod in this area grows faster and has lower $\mathrm{M}_{50}$ than further north. For 2004-2006 the weight-at-age in stock and maturity-at-age were therefore set to the level in 2003. Weight at age in catch was set to the level in 2002 because the proportion of cod caught in the southernmost area is supposed to decrease in 2004-2006 compared with 2003.

The recruitment (age 2) in 2004 was estimated using RCT3 with C regression and without shrinkage towards the mean since SSB has been steadily declining and is present at the lowest observed level. Shrinkage towards the mean would therefore probably overestimate the recruitment radically. A run using P-regression was also tried. However, this gave also recruitment at the same level as using shrinkage and well above the two latest observed year classes (year classes 2000 and 2001). Since the SSB has been declining substantially since 1999 the recruitment in 2004-2006 is supposed to be lower than the last estimated by the XSA ( 4.1 million). However, the recruiting year classes will not influence the SSB in 2005 and 2006 since hardly any of these are mature in 2006. Estimated number at age 1 from the Norwegian coastal survey was used as recruitment index, and the index in the 2003 survey was therefore used to estimate the 2002 year class (age 2 in 2004). The recruitment in 2004 was estimated to 2.7 million in 2004 and set to the same level in 2005 and 2006 (Table 2.20). It must be emphasized that the regression diagnosis is not very good $\left(\mathrm{R}^{2}=0.27\right)$. The reason for the bad $R^{2}$ is mainly caused by the 1994 year class. As 1 -year old in the survey this year class was observed as very weak.

The exploitation pattern is calculated using the average fishing mortality (age 4-7) from 2001 to 2003 scaled to the fishing mortality (age 4-7) in 2003. The scaling was used since there has been a trend towards fishing at older ages in recent years.

### 2.4 Methods Used in the Assessment

### 2.4.1 VPA and tuning (Table 2.8)

Tuning of the VPA was carried out using Extended Survival Analysis (XSA), using the default settings for the XSA with the following exceptions:

1. Catchability was set to be stock size independent for all ages. When examining the diagnostics from several exploratory runs in 2003 the regression statistics showed a slope not significant different from one when catchability was set to be stock size independent for all ages.
2. Catchability was set to be age dependent for ages 8 and older. This setting were obtained after examining the diagnostics of the mean log catchabilities from several exploratory XSA-runs in 2003 when changing this setting with one age at the time.
3. The survivors estimate was shrunk towards the mean F of the final 2 years since the exploitation pattern has changed the last few years. The 4 oldest ages are used in the shrinkage to stabilize fluctuations in historical Fvalues for ages 8 and above.
4. The standard error of the mean to which the survivor estimates are shrunk was set to 1.0 (Table 2.8). It was set above the default level because the coastal survey has shown a steadily decline in the latest years. The WG assumes the survey is reflecting the development of the stock and more weight is therefore assigned to the survey.

The XSA converged after 125 iterations. The log catchability residuals were positive for most of the ages in 2003, while they were negative for all ages below 8 for the 2002 survey. The Norwegian coastal survey in 2003 covered a larger area than the coastal surveys in 1995-2002. However, the survey indices are calculated the same way as previous years using the same covering area as in the previous surveys. The survey index in 2003 might still suffer from this and from comparing bottom trawl indices the index might be an overestimation. At next WG a bottom trawl index based on fixed trawl stations extending back to 1995 will be presented. The mean $\log$ catchabilities has slightly increased for ages 7 and 8 , and decreased for ages 6 and younger in this years assessment. This is probably the main reason to the observed retrospective pattern in fishing mortality.

### 2.5 Results of the Assessment

### 2.5.1 Fishing mortality and VPA (Tables 2.13-2.19, Figure 2.2)

The average ages $4-7$ fishing mortality in 2003 were estimated to be 0.62 (Table 2.13). This is the highest observed level (except for 1984) and well above the level in 2002 (0.46). Fishing mortalities tend to be overestimated while SSB tends to be underestimated in the assessment year as illustrated by the retrospective plots in Figure 2.3. If the retrospective pattern is continued the estimated $\mathrm{F}_{4-7}$ in 2003 is supposed to somewhat to high. However, the fishing mortality has increased substantially since 2000.

In 1990 and 1991 the lowest F -values was estimated ( 0.18 and 0.16 ). The fishing mortality was quite stable in the period 1996-2001 at a level of about 0.40 , but has for the last two years increased. The total biomass of the stock in the period from 1984-2003 has been between $69,000 \mathrm{t}$ and $314,000 \mathrm{t}$ (Tables 2.17, 2.19). In 2003 the biomass was estimated to be the lowest observed and about half the biomass in 2002. The spawning stock biomass has been between $38,000 \mathrm{t}$ and $197,000 \mathrm{t}$ (Tables 2.18, 2.19, Figure 2.2). As for the total stock biomass, the lowest observed SSB was estimated in 2003. The SSB has declined steadily from 1996 to present. The SSB in 2003 was only about half of the SSB in 2002. The decline both in the total stock biomass and the SSB has been accelerating, and will continue to decline unless the fishing mortality is substantially reduced.

A summary of landings, fishing mortality, stock biomass, spawning stock biomass and recruitment since 1984 is given in Table 2.19 and Figure 2.2.

### 2.5.2 Recruitment (Tables 2.7, 2.15, 2.19, 2.20)

Both the survey estimates of abundance in 2003 (age 1-4, Table 2.7), the XSA-estimate (age 2 and 3, Tables 2.15, 2.19) and result from the RCT3 (Table 2.20) indicate lower than average year classes from 1997-2002. These seven year classes are the lowest seven observed in the time series. The 2001 year class is the lowest observed in the time series, and the RCT estimate of the 2002 year class is even lower than the 2001 year class. Since 2001 the SSB has decreased further with approximately $50 \%$ and the probability of weak year classes the next few years is assumed to be high.

### 2.6 Catch Options for 2005 and Management Scenarios (Tables 2.22-2.23, Figure 2.2)

The total stock biomass and the SSB were further reduced during 2003 (respectively $17 \%$ and close to $27 \%$ ). The management option table (2.22) shows that the expected catch of $21,847 \mathrm{t}$ in 2004 (assuming F status quo) will give an unchanged fishing mortality $\left(\mathrm{F}_{2004}=0.62\right)$. The total stock biomass and the SSB will however be further reduced $(35,000$ t . and $24,000 \mathrm{t}$.). The status quo catch in 2005 is $14,373 \mathrm{t}$, and leads to a further decrease of the total stock biomass. In 2006 the total stock biomass and the SSB will be $25,000 \mathrm{t}$. and the $16,000 \mathrm{t}$., which is far less than half of the level in 2003. The SSB will not be rebuilt to the 2004 level even if the fishing mortality in 2004 is set to zero (Table 2.22). A catch of $5,000 \mathrm{t}(\mathrm{F}=0.18)$ brings the SSB up to the level in 2005 (Table 2.22, Figure 2.2).

### 2.7.1 Biomass reference points (Figure 2.4)

In the report of the study group on Precautionary Reference Points (February, 2003), the SG stated that the most recent recruitment values are very influential in the segmented regression, since recruitment is at age 2 . The analysis should therefore not include the final 2 data pairs since the assessment is still unstable. The time series is now extended with two more years and both the SSB and recruitment have further decreased.

The recruitment is clearly impaired at this low SSB level. When examining the retrospective pattern in SSB there is a trend towards underestimating the SSB in the assessment year (Figure 2.3). The retrospective pattern in recruitment is better and the estimated recruits have been quite stable since 2000 .

During this years meeting the WG has calculated potential candidates for $\mathbf{B}_{\mathrm{lim}}$ using segmented regression. Two different input data sets were examined. In the first data set, the last two year classes estimated in the XSA were excluded while in the second they were not (see table below). When excluding the latest two year classes the calculated $\mathbf{B}_{\text {lim }}$ was approximately 125,000 tonnes, while including them gave a $\mathbf{B}_{\text {lim }}$ of approximately 140,000 tonnes (see table below and figure 2.4). The sensitivity plots show that removing one more year (1999 year class) reduce the changepoint to about $110,000 \mathrm{t}$. Removing subsequently 8 further points makes no change in the changepoint. The conclusion is that reasonable $\mathbf{B}_{\mathrm{lim}}$ will be in the range 110-140,000 t .

However, there is a time-trend in the $\mathrm{SSB} / \mathrm{R}$ plot (Figure 2.4). The year classes 1986-1990 were all above average and originated from SSB below $140,000 \mathrm{t}$, while the year class 1997 originated from a SSB of more than $150,000 \mathrm{t}$. was well below average. The year classes 1986-1990 tends to reduce $\mathbf{B}_{\text {lim }}$, while for instance the year classes 1997 and onwards tends to increase the estimated $\mathbf{B}_{\text {lim }}$. In addition to SSB , environmental conditions or influence from other fish species might contribute these unexpected time trends of recruitment. However, the highest observed level of recruitment is only about twice average, while the lowest observed is about $1 / 10$ of the average.

The WG has examined potential candidates for $\mathbf{B}_{\text {lim }}$, but will at the time being not propose a specific $\mathbf{B}_{\text {lim }}$ because there seems to be a time trend in the data.

| Input year classes | Model | Resid df | RSS | F-Statistics | B-lim value (tonnes) | Bootstrap p-value |
| :--- | :--- | :--- | :--- | ---: | ---: | ---: |
| $1984-1999$ | Changepoint | $15(\mathrm{n}-1)$ | 3.104376 | 2.821350 | 125,493 | 0.0990 |
| $1984-2001$ | Changepoint | $17(\mathrm{n}-1)$ | 5.981249 | 7.613725 | 139,588 | 0.0099 |

### 2.8 Comments to the Assessment

### 2.8.1 A comparison of the assessment results and the survey results (Figure 2.1)

Both the assessment and the surveys from 1995-2003 show a steeply declining stock. For ages 2-8 the survey indices and the XSA estimates are well correlated (Figure 2.1). It therefore seems like the survey and the XSA assessment reflect the changes in the stock number quite well. There is a general trend towards decreasing catchability with increasing age.

### 2.8.2 Comparison of this years assessment with last years assessment (Figure 2.3)

Fishing mortalities tend to be overestimated while SSB tends to be underestimated in the assessment year as illustrated by the retrospective plots in Figure 2.3. The retrospective pattern for the recruitment is better, especially from 2000 and onwards. The calculated fishing mortality $\mathrm{F}_{4-7}$ and SSB in 2002 is lower ( $23 \%$ ) and SSB higher ( $4 \%$ ) in this years assessment compared with last years assessment (see below). The recruitment in 2002 (2000 year-class) is lower (19\%) in last years assessment compared with this year's assessment.

| Assessment year | $\mathrm{F}_{4-7}$ year 2002 | SSB year 2002 | Total stock biomass 2002 | Recruits age 2 year 2001 |
| :---: | :---: | :---: | :---: | :---: |
| 2003 | 0.60 | 76,443 | 121,818 | 6,055 |
| 2004 | 0.46 | 79,799 | 130,047 | 7,190 |

### 2.8.3

- The Norwegian coastal survey is the only survey covering the distribution area of the stock. The survey is conducted in the period October/November. In this period the maturity ogive can be difficult to define exactly and might influence the estimation of maturity-at-age and hence the estimation of SSB.
- The catches and survey indices are estimated by separating between coastal cod and Northeast Arctic cod by inspection of the otoliths. The precision and accuracy of the method is under investigation by comparison of different otolith readers and results from genetic investigation of the same otoliths. Preliminary results indicate more than $95 \%$ accuracy in the estimates.
- The retrospective pattern shows an overestimation of the F-values in the assessment year. The stock has been steadily declining for several years now. However, the catches are quite high which tends to push the historical stock upwards and the fishing mortality downwards. The accuracy of the estimated number might therefore be uncertain in the assessment year.
- The Norwegian coastal survey in 2003 covered a larger area than the coastal surveys in 1995-2002. However, the survey indices are calculated the same way as previous years using the same covering area as in the previous surveys. The survey index in 2003 might still suffer from this and from comparing bottom trawl indices the index might be an overestimation.

### 2.8.4 Management considerations

New regulations for coastal cod became operative in May 2004 (see chapter 2.1.2). In accordance with the precautionary approach and the state of the stock, the new regulations should be closely evaluated. In case the fishing mortality is not substantially reduced further action needs to be taken.

Recruitment from SSB below $100,000 \mathrm{t}$ is clearly impaired. The SSB is present the lowest observed and only $1 / 3$ of this level and at the beginning of 2005 will be $24,000 \mathrm{t}$ assuming F status quo in 2004. In that sense, SSB in 2004 will be well below any $\mathbf{B}_{\text {lim }}$ candidate, and the probability of further recruitment failure is likely to be very high. This being the case, the SSB should be rebuilt to a level where recruitment is not impaired before fishing is resumed.

### 2.9 Response to ACFM technical minutes

The review committee last year had some comments to the assessment;

- The values of the input tables are now checked for errors.
- More detailed explanations regarding the model inputs (e.g. RCT3 and XSA) are included in the text (2.3.6 and 2.4.1).
- More detailed explanations regarding diagnostics are included in the text (2.3.6 and 2.8.3).
- The XSA model showed a strong year effect in 2003 F estimates. This is further examined and discussed in the text (2.5.1), and a retrospective analysis of the XSA is included in this years report (2.8.2).
- A justification for the heavy reliance on the survey data for tuning the XSA model is included in the text (2.4.1).
- Uncertainties in the assessment is described in more detail in chapter 2.8.3.

### 3.1 Status of the fisheries

### 3.1.1 Historical development of the fisheries (Table 3.1)

From a level of about $900,000 \mathrm{t}$ in the mid-1970s, landings declined steadily to around $300,000 \mathrm{t}$ in 1983-1985 (Table 3.1). Landings increased to above $500,000 \mathrm{t}$ in 1987 before dropping to $212,000 \mathrm{t}$ in 1990, the lowest level recorded in the post-war period. The catches increased rapidly from 1991 onwards, stabilised around $750,000 \mathrm{t}$ in 1994-1997 but decreased to about $414,000 \mathrm{t}$ in 2000. The estimated catch in 2003 was about 522,000 tonnes. The fishery is conducted both with an international trawler fleet and with coastal vessels using traditional fishing gears. Quotas were introduced in 1978 for the trawler fleets and in 1989 for the coastal fleets. In addition to quotas, the fishery is regulated by a minimum catch size, a minimum mesh size in trawls and Danish seines, a maximum by-catch of undersized fish, closure of areas having high densities of juveniles and by seasonal and area restrictions.

### 3.1.2 Landings prior to 2004 (Tables 3.1-3.3, Figure 3.1)

## Total landings of cod in sub-area I and Divisions IIa and IIb:

Final official landings for 2002 amount to $464,839 \mathrm{t}$. The provisional official landings for 2003 are $450,493 \mathrm{t}$. Unreported landings of around $90,000 \mathrm{t}$ have been estimated both for 2002 and 2003.

## Landing figures used for the assessment of North-East Arctic cod:

The historical practise (considering catches between $62^{\circ} \mathrm{N}$ and $67^{\circ} \mathrm{N}$ for the whole year and catches between $67^{\circ} \mathrm{N}$ and $69^{\circ} \mathrm{N}$ for the second half of the year to be Norwegian coastal cod) lead to official landings of North-East Arctic cod of $445,045 \mathrm{t}$ in 2002 and $431,949 \mathrm{t}$ in 2003 (Table 3.1). For the assessment the estimated 90,000 tonnes of unreported catches was added both years.

The landings by area, split into trawl and other gears, is given in Table 3.2 and the nominal landings by country is given in Table 3.3. Compared to 2002, the landings in 2003 decreased in Division IIb and increased in Sub-area IIa (Table 3.1).

### 3.1.3 Expected landings in 2004

The mixed Norwegian-Russian fisheries commission agreed on a TAC of $506,000 \mathrm{t}$ for 2004 , including $20,000 \mathrm{t}$ Norwegian coastal cod.

The Working Group has no information on the size of expected unreported landings in 2004 but believes this could continue to be a problem.

### 3.2 Status of research

### 3.2.1 Fishing effort and CPUE (Table A1)

CPUE series of the Norwegian, Russian and Spanish trawl fisheries are given in Table A1. The data reflect the total trawl effort, both for Norway and Russia. The Norwegian series is given as a total for all areas (Table A1).

### 3.2.2 Survey results (Tables A2-A5, A10-A11, A14-A16)

With respect to year class strength, the overall picture seen in the surveys is summarized as follows: the 2001 and 2003 year classes are weak. The 2002 year class is also observed to below average in the latest survey, while it appeared more promising in earlier surveys. Most of the age groups in the fishable stock have increased in the last autumn survey compared to the year before, while they decreased in the last winter survey compared to the year before.

## Joint Barents Sea winter survey (bottom trawl and acoustics)

The preliminary swept area estimates and acoustic estimates from the Joint winter survey on demersal fish in the Barents Sea in winter 2004 are given in Tables A2 and A3.

Before 2000 this survey was made without participation from Russian vessels, while in the four latest surveys Russian vessels have covered important parts of the Russian zone.

It should be noted that the survey conducted in 1993 and later years covered a larger area compared to previous years (Jakobsen et al. 1997). In 1991 and 1992, the number of young cod (particularly 1- and 2-year old fish) was probably underestimated, as cod of these ages were distributed at the edge of the old survey area. Other changes in the survey methodology through time are described by Jakobsen et al. (1997). Note that the change from 35 to 22 mm mesh size in the codend in 1994 is not corrected for in the time series. This mainly affects the age 1 indices.

## Lofoten acoustic survey on spawners

The estimated abundance indices from the Norwegian acoustic survey off Lofoten and Vesterålen (the main spawning area for this stock) in March/April are given in Table A4. A description of the survey, sampling effort and details of the estimation procedure can be found in Korsbrekke (1997). There is still a high proportion of first time spawners in the survey.

## Norwegian summer/autumn survey

Table A5 gives the results of the Norwegian bottom trawl survey in the Svalbard and Barents Sea area in August/September. The results for the Svalbard area (Division IIb) have been used earlier in the XSA tuning but have been left out in the three latest assessments. The series given for the Barents Sea covers ICES Division IIa and IIb and the north-western part of sub-area I, and thus includes the Svalbard area estimates.

## Russian autumn survey

Abundance estimates from the Russian autumn survey (November-December) are given in Table A10 (acoustic estimates) and Table A11 (bottom trawl estimates). The Russian autumn survey did not cover the Norwegian economical zone in 2002. The indices obtained were adjusted assuming the area distribution to be equal to the 19982001 average. The 2003 survey was conducted with complete area coverage.

## International 0-group survey

Abundance indices of 0-group cod from the International 0-group survey are provided in Tables A14 and A15. It should be noted that in 1985 some gear changes were made, and the earlier part of the time series is now adjusted to take account of these changes (Nakken and Raknes 1996). The abundance of 0 -group cod was very low in 2001, and somewhat below average in 2002 and 2003. The same pattern is observed for age 1 of the same year-classes in the groundfish surveys. The 0 -group abundance in the years 1992-1997 is rather outstanding in the time series. Among those year-classes only 1994 and 1995 appear to be above average at age 3 in other surveys.

### 3.2.3 Age reading

The joint Norwegian-Russian work on cod otolith reading has continued, with regular exchanges of otoliths and age readers (Introduction chapter). Within laboratories (IMR, PINRO) and between laboratories (IMR-PINRO) differences in age reading will be presented at the 3rd International Symposium on otoliths (Australia, July 2004).

### 3.2.4 Length and Weight at age (Tables A6-A9, A12-A13)

Length at age is shown in Table A6 for the Norwegian survey in the Barents Sea in winter, in Table A8 for the Lofoten survey and in Table A12 for the Russian survey in October-December. Weight at age is shown in Table A7 for the Norwegian survey in the Barents Sea in winter, in Table A9 for the Lofoten survey and in Table A13 for the Russian survey in October-December.

Both the joint winter survey in 2004 and the Russian autumn survey in 2003 show decrease in weights for some ages (Table A7 and A13).

### 3.2.5

Historical (pre 1982) Norwegian and Russian time series on maturity ogives were reconstructed by the 2001 AFWG meeting (ICES CM 2001/ACFM:19). The Norwegian maturity ogives were constructed using the Gulland method for individual cohorts, based on information on age at first spawning from otoliths. For the time period 1946-1958 only the Norwegian data were available. The Russian proportions mature at age, based on visual examinations of gonads, were available from 1959.

Since 1982 Russian and Norwegian survey data have been used (Table 3.5). For the years 1985-2003, Norwegian maturity at age ogives have been obtained by combining the Barents Sea and Lofoten surveys according to the method described in Marshall et al. (1998). Russian maturity ogives from the autumn survey are available from 1984 until present. The Norwegian maturity ogives tend to give a higher percent mature at age compared to the Russian ogives, which is consistent with the generally higher growth rates observed in cod sampled by the Norwegian surveys. The approach used is consistent with the approach used to estimate the weight at age in the stock (described in Section 3.3.2). The percent mature at age for the Russian and Norwegian surveys have been arithmetically averaged for all years, except 1982-1983 when only Norwegian observations were used and 1984 when only Russian observations were used.

The 2003 AFWG report contains an extensive section (3.2.5), addressing several issues of cod maturity investigations. Essential work is still in progress. Possible intersessional work on refining the maturity ogives includes:

- review the comparability between the Norwegian and Russian maturity stages with particular reference to the procedures used to exclude fish with uncertain maturity stages or identify individuals that may have skipped spawning;
- fill in gaps in the Russian data (by regions and months) by smoothing data using appropriate weighting factors (Lepesevich 2002).
- review the procedures used to combine the Barents Sea Joint Winter survey and the Lofoten survey.

### 3.2.5.1 Status of research on reproductive potential of NA cod

Research is ongoing into developing alternative indices of reproductive potential for NEA cod (Marshall et al. 1998). This research is benefiting from the improved accessibility of both Norwegian and Russian databases.

Preliminary estimates of total egg production were presented to the 2003 AFWG (Needle and Marshall WD2, 2003). These estimates require further refinements before being considered as final. These refinements include: a) developing female-only maturity ogives for the full time period (1946-2001); b) refinements to the method of hindcasting fecundity and c) developing a model to incorporate maternal effects on egg viability. Female-only SSB will also be estimated for the full time period. Additionally, software tools are being developed to estimate alternative indices of reproductive potential from standard assessment output and link this information to both recruitment and medium-term stock projections.

### 3.2.5.2 Potential causes of interannual variation in maturity ogives

The maturity ogives used for the medium-term stock projections have a considerable impact on the forecasted SSB values. Average values are used, however, it would be advantageous to identify factors contributing to variation in maturity ogives. There is a positive relationship between weight-at-age and maturity-at-age for age-classes 8 to 10 (Fig. 1.7), and between weight-at-length and maturity-at-length (Fig 1.8). Liver weight estimates (g) of cod (derived from the Russian liver condition index and age/length keys described in Marshall et al., in press) show a significant, positive relationship with the proportion of mature fish for three length groups for the time period 1984 to 2001 (Fig. 1.9)(Marshall, presentation for ICES Symposium Cod and Climate, Bergen May 2004). This result confirms that the magnitude of stored energy is positively correlated with the proportion mature.

The 2004 maturity-at-age values for age classes 6 and 7 are slightly higher than those for 2003. This is a bit in conflict with present growth rates. However, it may be connected with maturity stages, assumed to be skipped spawners. A decrease of maturity rates may be forecasted in the short-term particularly given the high levels of cod biomass and potentially low capelin biomass.

Bogstad et al. (WD3) found the maturity at age to be correlated with the total stock biomass. However, their analysis was based on the whole time series (1946-2002), while the correlation between weight at age and maturity at age is clearly different between the 1946-1979 and 1985-2001 periods (Section 1.4.2.2). Thus, it may be worthwhile to look at density-dependence of maturation for those periods separately.

Possible future work on projecting maturity ogives includes:

- establish a method for predicting liver weights in the upcoming year. This research can take advantage of the links between capelin stock biomass and liver condition.

### 3.3 Data used in the assessment

### 3.3.1 Catch at age (Tables 3.8, 3.9 and 3.10)

For 2002, age compositions for all areas were available from Norway (by gears), Russia, Spain and Germany. Age compositions of the total landings were calculated separately in Sub-area I and Division IIa and IIb by using the age compositions that were available and raising the landings from other countries by Russian trawl (Sub-area I and Division IIa), and by Norwegian trawl (Division IIb). For 2003, age compositions for all areas were available from Russia, Norway, Germany and Spain. Length measurements were reported from Portuguese catches. On this basis Portuguese catches were distributed by use of the age composition in the Russian catches. Unreported catches in 2002 were distributed on ages using total international catch age distribution in Division Ilb only while in 2003 they were distributed using total international catch age distribution in Division IIb on half the unreported catch and total international catch age distribution in Sub-area I on the other half.

Table 3.8 show available catch at age data for all ages $1-15+$. The catch numbers shown in Table 3.10 together with cannibalism figures (Tables 3.9) were used in the XSA tuning.

### 3.3.2 Weight at age (Tables 3.4 and 3.11-3.12).

## Catch weights

For 2003, the mean weight at age in the catch (Table 3.11) was calculated as a weighted average of the weight at age in the catch for Norway, Russia, Germany and Spain. The weight at age in the catch for these countries is given in Table 3.4 .

## Stock weights

Since ages 12 and 13+ are scarce in the survey samples, fixed values for ages 12 to $15+$ has formerly been used (set equal to typical weights for these ages observed in catches). Since the 2000 working group the assessment has applied 13 as plus group.The $13+$ weights is now calculated year by year as a weighted mean of the former fixed values for older ages.

For ages 1-11 stock weights at age $\mathrm{a}\left(\mathrm{W}_{\mathrm{a}}\right)$ at the start of year y for 1983-2004 (Table 3.12) were calculated as follows:
$W_{a}=0.5\left(W_{\text {rus }, a-1}+\left(\frac{N_{\text {nbar }, a} W_{\text {nbar }, a}+N_{\text {lof }, a} W_{\text {lof }, a}}{N_{\text {nbar }, a}+N_{\text {lof }, a}}\right)\right)$
where
$W_{r u s, a-1}$ : Weight at age a-1 in the Russian survey in year y-1 (Table A13)
$N_{\text {nbar }, a}$ : Abundance at age a in the Norwegian Barents Sea acoustic survey in year y (Table A2)
$W_{n b a r, a}$ : Weight at age a in the Norwegian Barents Sea acoustic survey in year y (Table A7)
$N_{\text {lof }, a}$ : Abundance at age a in the Lofoten survey in year y (Table A4)
$W_{l o f, a}$ : Weight at age a in the Lofoten survey in year y (Table A9)

### 3.3.3 Natural mortality

A natural mortality of 0.2 was used. In addition, cannibalism was taken into account as described in Section 3.4.2. The proportion of F and M before spawning was set to zero.

### 3.3.4 Maturity at age (Tables 3.5 and 3.13)

As noted in Section 3.2.5, arithmetic averages of the Russian and Norwegian maturity at age values were used for 19852003.

### 3.3.5 Tuning data (Tables 3.14 and 3.15)

The following surveys and commercial CPUE data series was used for initial tuning runs by single fleets:

|  | Name | Place | Season | Age | Years |
| :--- | :--- | :--- | :--- | :--- | :--- |
| Fleet 17 | Russian bottom trawl surv. | Total area | Oct-Dec | $3-8$ | $1982-2003$ |
| Fleet 09 | Russian trawl CPUE | Total area | All year | $9-12$ | 1985-2003 |
| Fleet 15 | Joint bottom trawl survey | Barents Sea | Feb-Mar | $3-8$ | 1981-2004 |
| Fleet 16 | Joint acoustic survey | Barents Sea + Lofoten | Feb-Mar | 3-11 | 1985-2004 (Table A16) |

The output tables from the tuning include ages 1 and 2 , just to show the year-class abundance at age 1 and 2 created by the cannibalism numbers used in the tuning.

As in earlier assessments the surveys that were conducted during winter were allocated to the end of the previous year. This was done so that data from the surveys in 2004 could be included in the assessment. Some of the survey indices have been multiplied by a factor 10. This was done to keep the dynamics of the surveys even for very low indices, because XSA adds 1.0 to the indices before the logarithm is taken. The tuning fleet file is shown in Table 3.14.

Tuning of the VPA was carried out with XSA using default settings with the following exceptions:

1. Tapered time weighting power 3 over 10 years
2. Catchability dependent of stock size for ages less than 6
3. F of the 2 oldest age groups used in F shrinkage
4. Standard error of the mean to which estimates are shrunk set to 1.0

These settings are identical to those used by last years Working Group. The reasoning for keeping the same settings and tuning data are given in section 3.4.1.

### 3.3.6 Recruitment indices (Tables 3.6 and 3.7)

The survey data on ages 0,1 and 2 in the autumn survey and ages 1,2 and 3 in the joint winter survey are not used in the XSA, and are instead used to estimate the year-class strength at age 3 by making regressions with VPA estimates of recruitment at age 3 (the RCT3-program in the ICES software). The input is shown in Table 3.6, and the output is shown in Table 3.7.

### 3.3.7 Cannibalism

The method used for calculation of the consumption is described by Bogstad and Mehl (1997). It should be noted that the temperature is used in these calculations. The estimates were obtained as follows:

The cod stomach content data were taken from the joint PINRO-IMR stomach content database (methods described in Mehl and Yaragina 1992). On average 7,500 cod stomachs from the Barents Sea have been analysed annually. The stomachs are sampled throughout the year, although sampling is less frequent in the second quarter of the year. The consumption calculations have been updated by data for 2003 as well as additional data for 2002. The Barents Sea was divided into three areas (west, east and north) and the consumption by cod was calculated from the average stomach content of each prey group by area, half-year and cod age group.

The number of cod predators at age is taken from the VPA, and thus an iterative procedure has to be applied (Section 3.4.2). It was assumed that the mature part of the cod stock is found outside the Barents Sea for three months during the first half of the year. There were very few samples of the stomach contents of cod in the spawning areas. Thus, consumption by cod in the spawning period was omitted from the calculations. It is believed that the cod generally eats very little during spawning, although some predation by cod on herring has been observed close to the spawning areas. The geographical distribution of the cod stock by season is based on Norwegian survey data. The total number of cod ages $0-6$ (million) consumed is given in Table 3.9. Alternative calculations of the number of cod consumed by cod, giving somewhat different results, were presented in WD 4.

### 3.3.8 Prediction data (Tables 3.23 and 3.28, Figure 3.2 and 3.14a)

The input data to the short-term prediction with management option table (2004-2006) are given in Table 3.28. For 2004 stock weights and maturity were taken from surveys as described in Sections 3.3.2 and 3.3.4.

Catch weights in 2004 onwards and Stock weights in 2005 onwards are predicted by the method described by Brander (2002), where the latest observation of weights by cohort are used together with average annual increments to predict the weight of the cohort the following year.
$\mathrm{W}(\mathrm{a}+1, \mathrm{y}+1)=\mathrm{W}(\mathrm{a}, \mathrm{y})+\operatorname{Incr}(\mathrm{a})$, where $\operatorname{Incr}(\mathrm{a})$ is a "medium term" average of $\operatorname{Incr}(\mathrm{a}, \mathrm{y})=\mathrm{W}(\mathrm{a}+1, \mathrm{y}+1)-\mathrm{W}(\mathrm{a}, \mathrm{y})$
This method was introduced in the cod prediction in last years working group. Then it was decided that for Catch Weights average annual increments by age were calculated for the period 1994-2001 (based on weights for the period 1994-2002), and for Stock Weights average annual increments by age were calculated for the period 1995-2002 (based on weights for the period 1995-2003). Last years predictions fit well with the new observations on weights.

For the current predictions it was decided to follow the same procedure, except that for stock weights the period (20012003) was chosen for calculating average annual increment. The reason was that those years indicate a declining trend that could be associated with declining capelin stock. Figures 3.2 a and 3.2 b show how these predictions perform back in history. Evidently the fit is best over the period which is the basis for calculated $\operatorname{Incr}(\mathrm{a})$.

Last year the maturity ogive for the years 2004 and 2005 was predicted by using the 1984-2002 average. This is well below the ogive observed in 2004. The 2002-2004 period now appears rather stable, and an average over that period was applied. The exploitation pattern in 2004 and later years was set equal to the 2001-2003 average. The reference F was also averaged over the same period. Taking into account the uncertainty of the estimated F in 2003, it was concluded that there might not be a clear trend in F over this 3-year period.

The stock number at age in 2004 was taken from the final VPA (Table 3.23) for ages 4 and older. The recruitment at age 3 in year 2004 and later was estimated from surveys (section 3.3.6). Fig. 3.14a shows the development in natural mortality due to cannibalism for cod (prey) age groups 1-3 together with the abundance of capelin in the period 19842003. It is seen that the level of cannibalism is inversely related to the capelin abundance. Models for predicting cannibalism was presented in WD 10. High correlation was observed between the cod ssb and cannibalism mortality 3 years later. The group felt that this should be further explored, especially for a better understanding of the cause/ effect leading to such a relationship (section 1). For the current prediction the 2001-2003 average natural mortality was used.

### 3.4 Methods used in the assessment

### 3.4.1 VPA, tuning and sensitivity analysis

For several years each new assessment of this stock has shown a considerable downward revision in population size. This has been clearly shown both in the Quality Control Diagrams and in the retrospective analysis presented by some earlier Working Groups. In the assessments in August 2000, several changes in model settings and data choices were made, and since then the retrospective analysis has considerably improved, and the Quality Control Diagrams now indicate rather consistent assessments since 1999.

There were no changes in the present assessment method compared to last year.
The present assessment applies the same fleets and age groups as used since the 2000 assessment, with the exception that Norwegian trawl CPUE has been left out since the 2002 assessment. It was, however discovered that in last years assessment the ages were mis-specified in fleet 17. This was corrected and the 2003 assessment was rerun. For 2002 this gave $3 \%$ decreased SSB and $3 \%$ increased F .

The last ACFM technical minutes comments on the use of some of the fleet data and recommends evaluation of the survey data included and their influence on the results. Figures 3.3 a and b show the tuning indices by age, all scaled to their average over the period 1994-2003 (the year range used for tuning) and Figures 3.4-3.7 show fleet-wise plots from the "surba" program (Needle, 2003 and Needle, 2004). Figure 3.8 shows residuals of log catchability from a run based on the settings and fleet data described above (and cannibalism "tuned" as described in section 3.4.2). High catchability residuals (Figure 3.8), discrepancies compared to other fleets (figure 3.3) and internal inconsistencies (Figures 3.4-3.7) are observed for age 12 in fleet 09 , ages 10 and 11 in fleet 16 and ages 6,7 and 8 in fleet 17 . An alternative tuning with those mentioned fleet data removed was made. The XSA diagnostics (Table 3.16b) improved compared to the "standard" run (Table 3.16a). Table 3.15b compares population numbers and Fs and shows that the differences between the two were marginal ("Final run" vs. "Ages with high Qres removed").

Table 3.15b also compares single fleet runs (with original data) with the final run. Figure 3.9 shows that $\mathrm{F}_{4-8}$ follows better the expected "F-Biomass curve" than $\mathrm{F}_{5-10}$ does. This is because the largest relative differences between fleets are observed on ages $9-10$, which has much more influence on $\mathrm{F}_{5-10}$ than on the SSB. It is noticed that the final run gives a quite low F and a high SSB compared to the single fleet runs (Figure 3.9). Since shrinkage works differently on single fleet runs than on a combined run, the fleet predictions before shrinkage (the 2003 values of F and survivors at age taken from the XSA diagnostics of single fleet runs) was examined. Figures 3.10 and 3.11 show corresponding F and stock number by age before shrinkage (left hand panels) and after shrinkage (right hand panels) in single fleet runs. Open symbols means that there is no tuning data for that fleet at that age. Before shrinkage it is observed that in all cases the combined run is located near the fleets having highest weight in combined tuning (although the distance between some fleet values are rather large). The point "ALL" for the combined is with shrinkage in both the left and right panels, which means that this point is fixed and we can see how the fleets move relative to ALL as effect of the shrinkage. In general shrinkage brings the points closer to each other, because they are influenced by the same external signals. For the age groups 3-7 they are reasonably distributed around ALL also after shrinkage. For age 8 and 9 the shrunk values moves somewhat to the left and ALL appears rather extreme.

Figure 3.9 and the right hand panels of Figures 3.10 and 3.11 tell us the result we would get if we only had that single survey available and still chose to use the same shrinkage settings in the tuning. The left hand panels in Figure 3.9 are the relevant ones for evaluating the direct effect of the surveys. The pattern seen was considered satisfactory, although the uncertainty appears large for Fs and survivors for age 9 and older. The run where ages with high q-residuals were removed from tuning fleets did not give any obvious gain in precision on age groups 9 and older, and the SSB / F for single fleets did not improve (Figure 3.12). This together with the observation that Fs and population numbers did not change for the run with these refined fleets led to the conclusion that the "standard" run was kept. One reason for being restrictive towards changes in settings and choices of data is that the PA reference points for this stock is based on a retrospective run with fixed settings and input data.

Table 3.15 b also shows the effect of changing ages for stock size dependent catchabilities (less than age 4,5 and 7 , compared to 6 in "final run"). The current assessment is very little sensitive to this choice, while in the mid 90ies this choice was quite critical. An increased tuning window ( 15 yrs compared to 10 ) increased $\mathrm{F}_{5-10}$ by $13 \%$ and reduced SSB by $6 \%$. The earlier part of the survey series show larger discrepancies between surveys (Figure 3.3) and larger internal residuals (bubble plots, Figures 3.3-3.6). Thus an increased time window may introduce a bias. The 2000 working group observed a considerably worse retrospective pattern when the tuning window was increased.

The tuning appears to be rather sensitive to the level of shrinkage. Increasing the F and population shrinkage (reducing minimum SE for shrinkage values from 1.0 to 0.5 ) lead to $37 \%$ increase in $\mathrm{F}_{5-10}$ and $14 \%$ reduced ssb. Such a tendency should be expected since the assessment indicates declining trend in $F$. The argument for keeping low shrinkage is that the assessment should be able to pick up recent trends in the surveys.

The effects of adding different amounts of unreported catch in 2002 and 2003 are shown in Table 3.15a and Figure 3.15 .

### 3.4.2 Including cannibalism in the VPA (Tables 3.16-3.20, 3.22)

For the cod assessment data from annual sampling of cod stomachs has been used for estimating cannibalism, since the 1995 assessment. The argument has been raised that the uncertainty in such calculations are so large that they introduce too much noise in the assessment. A rather comprehensive analysis of the usefulness of this is presented in Appendix 1. The conclusion is that it improves the assessment.

The following procedure was followed: As a starting point the number of cod consumed by cod were estimated from the stock estimates in the last assessment. Then the number consumed was added to the catches used for tuning. The
resulting stock then lead to new estimates of consumption. This procedure was repeated until the revision of consumed numbers for the latest year (2002) differed less than $1 \%$ from the previous iteration.

The tuning diagnostics from XSA with cannibalism are given in Table 3.16 and the total fishing mortalities (true fishing mortality plus mortality from cannibalism) and population numbers in Tables 3.17 and 3.18.

In order to build a matrix of natural mortality which includes predation, the fishing mortality estimated in the final XSA analyses was split into the mortality caused by the fishing fleet (true F) and the mortality caused by cod cannibalism (M2 in MSVPA terminology) by using the number caught by fishing and by cannibalism. The new natural mortality data matrix was prepared by adding 0.2 (M1) to the M2. This new M matrix (Table 3.19) was used together with the new true Fs to run the final VPA on ages 3-13+. M2 and F values for ages 1-6 in 1984-2003 are given in Tables 3.20 and 3.22.

Cannibalism on cod age 3 and older may of course also have occurred before 1984. Thus, there is an inconsistency in the recruitment time series. For comparison with the historic time series an additional VPA with the same terminal Fs and fixed natural mortality ( 0.2 ) is presented (Table 3.27).

### 3.5 Results of the assessment

### 3.5.1 Fishing mortalities and VPA (Tables 3.21-3.26, Figures 3.1)

The estimated $\mathrm{F}_{5-10}$ in 2003 is lower than the assumed $\mathbf{F}_{\mathrm{sq}}$ in last years prediction ( $0.46 \mathrm{vs}, 0.70$ ), while the spawning stock biomass in 2004 is estimated to be $851,000 \mathrm{t}$, which is well above last year's assessment $(652,000 \mathrm{t})$.

The fishing mortalities and stock numbers are given in Tables 3.21-3.23, while the stock biomass at age and the spawning stock biomass at age are given in Tables 3.24-3.25. A summary of landings, fishing mortality, stock biomass, spawning stock biomass and recruitment since 1946 is given in Table 3.26 and Figures 3.1A and 3.1B.

Figure 3.13 shows the results of a retrospective analysis when cannibalism is taken into account. The number of cod consumed by cod was not recalculated year by year in the retrospective analysis, however.

### 3.5.2 Recruitment (Table 3.6-3.7)

From the RCT3 calculations the estimated number (millions) of recruits at age 3 is 276 millions for the 2001 year-class, 604 millions for the 2002 year-class and 455 millions for the 2003 year-class. A comparison of these results with the results of other recruitment models is given in Table 1.8.

### 3.6 Reference points

New reference points for Northeast Arctic cod were proposed by SGBRP in January 2003 (ICES CM 2003/ACFM:11) and adopted by ACFM at the May 2003 meeting.

### 3.6.1 Biomass reference points (Figure 3.1)

The values adopted by ACFM in 2003 are $\mathbf{B}_{\text {lim }}=220,000 \mathrm{t}, \mathbf{B}_{\mathrm{pa}}=460,000 \mathrm{t}$. (ICES CM 2003/ACFM:11).

### 3.6.2 Fishing mortality reference points

The values adopted by ACFM in 2003 are $\mathbf{F}_{\text {lim }}=0.74$ and $\mathbf{F}_{\mathrm{pa}}=0.40 .($ ICES CM 2003/ACFM:11)

### 3.7 Catch options (Table 3.29-3.30)

Catch options are presented in Table 3.29. The detailed outputs corresponding to $\mathbf{F}_{\mathrm{sq}}$ in 2004 and $\mathbf{F}_{\mathrm{pa}}$ in 2005 is given in Table 3.30.

In Figure 3.1 the catch level in 2005 and spawning stock biomass level in 2006 are plotted against the fishing mortality in 2005.

### 3.8.1 Adopted harvesting strategy

At the $31^{\text {st }}$ session of The Joint Norwegian-Russian Fishery Commission in autumn 2002, the Parties agreed on a new harvest control rule(section 3.12). This rule was applied for the first time when setting quotas for 2004.

### 3.8.2 Results

Prediction forecast:
Basis 2004: $\mathbf{F}_{\mathrm{sq}}=\mathrm{F}_{01-03}=0.63$, Catch $=696.000 \mathrm{t}$, leads to $\mathrm{SSB} 2005=794.000 \mathrm{t}$

| F | Basis | Landings 2005 | SSB 2006 |
| :--- | :--- | :--- | :--- |
| 0.00 | 0 | 0 | 1280 |
| 0.25 | $0.4 * \mathbf{F}_{\mathrm{sq}}$ | 302 | 1016 |
| 0.40 | $\mathbf{F}_{\mathrm{pa}}\left(=0.64 * \mathbf{F}_{\mathrm{sq}}\right)$ | 453 | 889 |
| 0.43 | Catch rule $\left(=0.69 * \mathbf{F}_{\mathrm{sq}}\right)$ | 484 | 862 |
| 0.50 | $0.8 * \mathbf{F}_{\mathrm{sq}}$ | 543 | 813 |
| 0.63 | $1.0 * \mathbf{F}_{\mathrm{sq}}$ | 646 | 729 |

### 3.8.3 Management considerations

The spawning stock in 2004 is above $\mathbf{B}_{\mathrm{pa}}$, and is expected to remain above in 2005. The fishing mortality has decreased somewhat from values around $\mathbf{F}_{\text {lim }}$ to an estimated value of 0.46 for 2003. This is the lowest since 1992, but still $15 \%$ above $\mathbf{F}_{\mathrm{pa}}$.

The forecasts indicate that fishing at $\mathbf{F}_{\mathrm{pa}}$ in $2005(453,000 \mathrm{t})$ allows the stock to remain above $\mathbf{B}_{\mathrm{pa}}$ in 2006.
The catch rule has been tested by simulations (Section 3.12). If appropriate action is taken when the stock is estimated to fall below $\mathbf{B}_{\mathrm{pa}}$ the rule is considered to be sufficiently precautionary. The simulation study proposes the following action to be appropriate for rebuilding when the stock falls below $\mathbf{B}_{\mathrm{pa}}$ : Catches should be restricted to a fishing mortality which linearly decreases from $\mathbf{F}_{\mathrm{pa}}$ to zero when estimated ssb decreases from $\mathbf{B}_{\mathrm{pa}}$ to $\mathbf{B}_{\mathrm{lim}}$. This also implies that there will be no restriction on the $\%$ annual change in TAC when the stock is below $\mathbf{B}_{\mathrm{pa}}$.

The catch in 2005 according to this rule is estimated to 484,000 tonnes, corresponding to $\mathrm{F}=0.43$ in 2005. These catch forecast covers all catches. It is then implied that all types of catches are to be included in this amount.

### 3.9 Comments to the assessment (Figures 3.2-3.6 and 3.13-3.16, Table 3.15 and 3.31).

There are indications of reduced precision of the surveys in the latest two years compared to those in the previous 2-3 years. The Russian autumn survey was not allowed to cover the Norwegian Zone in 2002, and the results of the Joint winter survey in 2003 now appears as an overestimate compared both to the survey in 2004 and 2002.

Previous Working Groups have been concerned about possible discarding and under-reporting (Introduction, and ACFM CM 2001/ACFM:02). This creates uncertainties in the catch statistics and undermines the basis for the assessment and catch predictions. The Working Group has underlined that this is a strong reason for additional precaution when setting quotas. Seeking for a more realistic assessment AFWG, along with official catch statistics used information on unreported catches for 2002 and 2003, as it was earlier done for the years 1990-1994. Uncertainties are nevertheless present. It is because estimates of unreported catches are quite provisional and requires more precise estimation and further consultations of relevant authorities at international level. AFWG was informed that 2002 and 2003 have been exceptional years with respect to unreported landings due to reasons explained in the introduction chapter. Incorporation of unreported catches for two years may lead to inconsistent corrections in the long-term series back in history. Further studies are required to evaluate the effect of uncertain estimates of unreported catches on the relationship between VPA and survey data.

Some analysis of the sensitivity of how vpa results changes at various levels ( $0,50,100$ and $200 \%$ ) of unreported catch for 2002 and 2003 are shown in Table 3.15a and Figure 3.15. Here the percentage relates to the amount of unreported catch used in the final VPA $(50 \%=45,000$ tonnes, $200 \%=180,000$ tonnes $)$.

A time series of discard estimates for cod was presented at the 2002 WG (Dingsør, 2001). Some results are shown in Table 3.31. At last years working group new estimates were presented for more recent years (WD 9, 2003). The results in the overlapping years of these two studies differ considerably. The discrepancies should be clarified before these time series are used in the assessment.

### 3.9.1 Comparison of this year's assessment with last year's assessment

The text table compares this years estimates with last years estimate for the year 2003 for number at age, total biomass, spawning biomass and reference F-values, as well as reference F for the year 2002. It also includes the results of rerunning the 2002 assessment with unreported catch added, and with fleet adjustments (section 3.4.1), as well as the 2003-assessment based on official catch only.

The final assessment values are fairly close to the 2003 assessment. Largest deviations are at age 3 and age 10. The upward revision of stock numbers at age 10 contributes considerably the observed decrease in $\mathrm{F}_{5-10}$, compared to the $\mathbf{F}_{\mathrm{sq}}$ assumption for 2003. Technically it is more relevant to compare the current assessment with the rerun 2003 assessment adjusted for unreported catch and changes in fleet data. Similar differences are observed here. F has decreased by $14 \%$ in 2002 and by $41 \%$ compared to the $\mathbf{F}_{\text {sq }}$ assumption for 2003, and stock numbers have decreased for ages 3-5, and increased for ages 8 and older. The new estimate of SSB in 2004 ( 851,000 tonnes) is considerably above the prediction from last year ( 652,000 tonnes). Increased stock numbers and increased proportion mature contribute about equally to this upward revision of SSB.

Retrospective plots of $\mathrm{F}, \mathrm{SSB}$ and recruitment are shown in Figure 3.13. Here the pattern for $\mathrm{F}_{4-8}$ is shown for comparison. This shows less between year revision than the $\mathrm{F}_{5-10}$, particularly some years back in time. This is most likely caused by some sampling noise associated with the age groups 9 and 10 , which in some years are rather scarce in some fishing fleets and survey fleets.

### 3.9.2 Comparison with other sources of stock indicators.

Comparisons with individual surveys are shown in Figure 3.2a. Here they are plotted against years as used in the tuning. Since the surveys take place late in the year, it is more relevant to compare with years and ages shifted for the surveys (Figure 3.2b). Here fleet 15 is rather parallel to the VPA, but tend to be somewhat below for ages 5-8, while the other fleets fluctuates around the VPA. The mortality trends for the surveys as seen from the "surba" analysis (Figures 3.43.7) are quite noisy, but an observed declining trend over the latest year is in general agreement with the recent mortality trends in the VPA. Figure $3.14 b$ compares the survey Fs and Fs from VPA.

A "calibrated" prediction of stock numbers from the Joint bottom trawl survey (WD 26) indicated lower abundance of ages 4-6 compared to VPA and Fleksibest (section 3.10), as shown in the table below. For older fish all estimates are in fair agreement.

|  | Stock number 2004, ages 4-6 | Stock number 2004, ages 7+ |
| :--- | :--- | :--- |
| Survey pred. Regres through origin | 585 | 207 |
| Survey pred. Regres with intercept | 703 | 191 |
| Vpa | 836 | 217 |
| Fleksibest | 820 | 198 |

The cpue for the Norwegian trawl fleet has not been used in tuning since the 2001 assessment. Figure 3.16 shows effort, catch per effort and F per effort. Partial Fs for the fleet is calculated as described in WD 25 on the basis of the final VPA. The increasing trend in F per unit effort since around 1990 show that the fishing efficiency have increased and cpue for this fleet is a biased indicator of the stock size.

### 3.10 Alternative assessment methods (Fleksibest)

### 3.10.1 Introduction

A description of the mathematical formulations used in Fleksibest is given in Frøysa et al. (2002). Changes in the model since last year are described in Bogstad et al. (WD 14). Fleksibest is a length-structured extension of the type of age structured assessment models sometimes termed 'statistical catch at age analysis' (Fournier and Archibald, 1982; Deriso et al., 1985). As last year, a complete assessment including a medium-term prediction is presented for comparison with the XSA assessment. An outline of the plans for future work on Fleksibest is given in the Introduction section.

### 3.10.2 Stock assessment using Fleksibest

### 3.10.2.1 Model structure

A quarterly time step is used. The model is run for the period 1.quarter 1985-1.quarter 2004. The age range has been extended so that it is possible to run the model on age range $1-12+$. The cod stock is divided into an immature (ages 110 , lengths $5-105 \mathrm{~cm}$ ) and a mature part (ages $4-12+$, lengths $55-135 \mathrm{~cm}$ ). Maturation takes part at the end of the fourth quarter each year. 1 cm wide length groups are used in the model, and 5 cm wide length groups in the survey and catch data files.

### 3.10.2.2 3.10.2.2 Data used

Survey data

The same surveys as in last year's assessment were used. Some age and length groups with few or very noisy observations are deleted from some surveys. The table below shows the year, age and length range for the surveys used.

| Survey | Quart <br> er | Year range | Age range | Length <br> range | Stock covered |
| :--- | :--- | :--- | :--- | :--- | :--- |
| Norwegian Winter bottom <br> trawl | 1 | $1985-1993$ | $3-9$ | $20-90 \mathrm{~cm}$ | Immature |
| Norwegian/Joint Winter <br> bottom trawl | 1 | $1994-2004$ | $1-9$ | $5-90 \mathrm{~cm}$ | Immature |
| Norwegian Winter acoustic | 1 | $1985-1993$ | $3-9$ | $20-90 \mathrm{~cm}$ | Immature |
| Norwegian/Joint Winter <br> acoustic | 1 | $1994-2004$ | $1-9$ | $5-90 \mathrm{~cm}$ | Immature |
| Lofoten acoustic | 1 | $1985-1989$ | $5-12+$ | $55-110 \mathrm{~cm}$ | Mature |
| Lofoten acoustic a and 1995- | $1-8$ | $55-110 \mathrm{~cm}$ | Mature |  |  |
| Russian bottom trawl <br> autumn | 1 | $1990-2004$ and | Immature and <br> mature |  |  |

The Norwegian (from 2000 Joint) winter survey in the Barents Sea (bottom trawl and acoustic indices) was split into two time periods because of the change of gear and increase in area coverage in 1994 (Jakobsen et al., 1997). The Lofoten acoustic survey was split into two periods because of the change of echosounder in 1990 (Korsbrekke, 1997).

The 1994 data from the Russian bottom trawl survey gave extremely high residuals and were removed. The XSA also indicates a bad fit for this survey in 1994.

## Catch data

As last year, it was decided to allow for treating the gillnet fishery separately from the other fleets, as this fleet is fishing on much larger fish than the other fleets. This is further discussed in Section 3.10.3. Thus, we use catch in numbers at age and length by quarter from the following two fleets:

- Combined fleet: All Norwegian fleets except gillnet (Danish seine, handline, longline, Norwegian trawl)+ Russian trawl
- Gillnet

Data for 1985-2003 are used, for length groups 5-135 cm and ages 1-12+.

In addition, two fleets contribute to the catch in the model: Third countries and Overfishing. For both of these fleets, it is assumed that the given catch in tonnes is caught, with the same selectivity as the combined fleet.

## Consumption data

Data on the consumption ( $\mathrm{kg} /$ time step) of cod by cod for the period 1985-2003 calculated in the same way as in Bogstad and Mehl (1997) are available. The data are given by predator age group and prey length group. For technical reasons, the consumption data could not be included in the objective function after the change from modeling cannibalism as mortalities to modeling cannibalism as predation. This will be implemented in the next release of the Gadget software and in the Fleksibest model.

## Differences between data used in XSA and in Fleksibest

It should be noted that there is some difference between the tuning series used in XSA and in Fleksibest. The older part of all the survey time series are downweighted in XSA. In Fleksibest, all years are given the same weight, but the Norwegian winter bottom trawl survey, the Norwegian winter acoustic survey and the Lofoten survey are split into two time periods. Also, the Norwegian winter acoustic survey and the Lofoten survey are combined in XSA, but not in Fleksibest.

### 3.10.2.3 Model assumptions

The Pearson function, which is scale dependent, was used as an objective function.
The length selectivity was assumed to be a logistic function of length for all surveys. Also for the commercial fleets a logistic length selection curve was assumed.

Linear mean growth in length, variable by year, was assumed. The ratio between the growth rate of mature and immature fish was assumed to be the same for all years.

The maturation parameters were estimated to values giving clearly lower values for maturity at age than in the input to the XSA. Last year, the maturation parameters were fixed to values giving maturity ogives similar to the values used as input to the XSA. Including data for abundance of first-time and repeat spawners from the Lofoten survey could improve the estimation of maturation. First-time spawners and repeat spawners would then have to be modeled as separate stocks. For 1987, when the condition factor was very low, Fleksibest gives higher maturity ogives than XSA. This difference from the overall trend could possibly be accounted for by also including the condition factor in the maturation function, a feature which is now included in the Gadget software. Taking weight at length into account when predicting maturation is essential, as discussed in Section 1.4.2.2.

The values of the contribution to the objective function from catches were upweighted compared to the surveys in order to get approximately the same contribution to the total value of the objective function for both groups of data sources.

### 3.10.2.4 Optimization algorithm

A combination of the Simulated Annealing and Hooke \& Jeeves algorithms was used. Repeated searches with the combination of these algorithms were performed, starting at the optimum found during the previous search. Sensitivity tests indicate that a minimum was found for the key run.

### 3.10.2.5 Changes from last year

- Possible age range extended from age 3-12+ to 1-12+
- Fishing mortality modeled as effort and cannibalism modeled as predation
- Different handling of catches by third countries and unreported overfishing
- Length selectivity of surveys changed from linear to logistic
- New software used

## Age range extended down to age 1

The maximum age range in the model was extended down to age 1 , and the length range of the immature cod was extended down to 5 cm . The age and length range of the survey data files was extended accordingly. The age and length range of the Norwegian (Joint) bottom trawl and acoustic surveys was only extended for the period 1994-2004. The reason for this is that an inner net was introduced in this survey in 1994 (Jakobsen et al. 1997). Before the inner net was introduced, the data for age 1 and 2 fish in these surveys are very noisy.

## Modeling of fishing and of cannibalism

Catch is now modeled by modeling effort, while previously it was modelled using fishing mortalities. This was done in order to comply with the overall modeling approach within the Gadget framework. The details of the modeling approach are described in Bogstad et al. (WD 14). Similarly, cod cannibalism is modelled as predation, not as mortality.

## Modeling of catches by third countries and of unreported catches

The catch of third countries and the assumed unreported overfishing is modeled by assuming that the given catch in tonnes is caught, with the same selectivity as the combined fleet. Previously, the ratio between the F from these fleets and the F generated by the combined fleet was assumed to be the same as the ratio between the catch in tonnes of the fleets.

## Length selectivity of surveys.

The length selectivity is now described by logistic curves for all surveys.

## Software used

Model runs are now performed using Gadget version 2.0.05. Previously, a custom IMR version of the Gadget software was used.

### 3.10.2.6 Estimates of parameters outside the model

The mean length at age and the standard deviation of the mean length at age for all age groups of immature and mature fish in the first year were taken from survey data. The SD of mean length of mature in the first year was not available, and was set to values obtained during previous estimations. The ratio between growth of immature and mature fish was also taken from previous runs. The number of fish in the first year in age groups with low abundance was fixed. The residual natural mortality was set to 0.2 . The weight-length relationship used is the same as for Norwegian commercial catch data. This relationship is variable by quarter and year.

### 3.10.3 Results from the assessment

## Choice of key run

Four different runs were made: age range 1-12+ and 3-12+, both with 1 fleet or 2 fleets (gillnet and combined). An 1+ Fleksibest model should be able to give a more coherent picture of the abundance of the youngest age groups (1-3) than an XSA with cannibalism included. The main reason for this is that in the XSA with cannibalism, the numbers consumed at age are treated as exact numbers in the same way as the catch at age. The survey data for ages 1 and 2 are only taken into account in the RCT3 prognosis and not in the assessment of historical abundance of the youngest age groups. With a model like Fleksibest, where catch as well as cannibalism is modeled, the number at age 1-3 could be calculated taking all data sources into account. Since the consumption data could not be included in the objective function this year, the results of the $1+$ runs were not considered to be reliable. Both the $1+$ and $3+$ runs gave approximately the same stock size for $4+$ fish. The runs with 1 and 2 fleets gave approximately the same fit to the data, but the exploitation pattern obtained from the run with 2 fleets was considered to be more likely, and thus the $3+$ run with 2 fleets was chosen as the key run, as in last year's Fleksibest assessment.

## Parameter sensitivity

Components of the objective function, input data and parameter estimates for the key run are given in Table 3.32a-c. The effect on the total objective function score of changing each parameter with $+/-5 \%$ is given. Sensitivity tests show that the estimation procedure has found a well-defined optimum, and that the objective function is quadratic around the optimum with respect to each parameter.

It is seen that the total objective function score is most sensitive to $\mathrm{L}_{50}$ (length at $50 \%$ selection) in the commercial fleets. It is also quite sensitive to the growth parameters and the length of a cohort at age 3 .

## Model results

The natural mortality, maturity, stock weight, catch weights and catch in numbers by age group from the key run are given in Table 3.33. This table also presents the fishing mortalities, stock numbers, stock biomass and spawning stock biomass. Results (total stock biomass, SSB, F, catches, recruitment, total stock number) of the key run are shown in Fig. 3.17 a-f. The total annual catch in weight as estimated by the model is somewhat higher than the reported catches in almost all years, but in general there is good agreement with the reported catches in tonnes. The maximum discrepancy is about 140000 tonnes in 1995. In general, the trends given by XSA and Fleksibest are very similar for the fishing mortality and stock biomass. Fleksibest shows the same overall trends for $\mathrm{F}_{5-10}$ as XSA, but the curve given by Fleksibest is smoother. One reason for this may be that Fleksibest is less vulnerable to noise in the catch data of the oldest ages due to the fixed selectivity pattern by length. The trends in total stock biomass are very similar.

The estimated maturation parameters gave lower maturity at age than the XSA assessment. Last year the maturation parameters were fixed at values which gave approximately the same maturity ogives as the XSA assessment. From the Lofoten survey, separate estimates of the number of first-time and repeat spawners are available. These estimates could be used to improve the estimation of the maturation parameters and thus the estimate of the spawning stock.

Compared to last year's Fleksibest results, the results obtained this year give a similar view of the status of the stock. The fishing mortality ( $\mathrm{F}_{5-10}$ ) in 2002 decreased from 0.58 in last year's assessment to 0.56 in this year's assessment, while the total stock biomass in 2003 was about 1.75 million tonnes in both assessments.

### 3.10.4 Retrospective analysis

Results (total stock biomass, SSB, F, catches, recruitment, total stock number) of a retrospective analysis with the same settings as in the key run are shown in Figure 3.18a-f. The runs stops in first quarter, and are labeled after the year that contains the last time step. The shortest run stops in first quarter in 1999, and is thus labeled 1999. The retrospective pattern seems to be quite consistent back to 1999.

### 3.10.5 Use of Fleksibest for predictions

Fleksibest is well suited for prognosis, because the length-dependence of population dynamics processes makes it easy to get consistency between the values of weight, maturity and mortality at age. In the prognosis runs with Fleksibest for the period 2004-2006, the same values as in the key run were used for most parameters. The growth parameter was set to the average of the 2001-2003 values, and the weight at length was set equal to the 2003 values. The mean length of
age 3 fish in 2005 and 2006 was set approximately equal to the 2004 value. The distribution of the catch taken by each of the two fleets was set equal to the 2003 value. The recruitment at age 3 in 2005 and 2006 is set to the values obtained from the RCT3 analysis. This is consistent with the assumptions made in the medium-term prognosis based on the XSA run (see Section 3.3.8).

The values of recruitment, catch weight, stock weight, maturity, natural mortality and fishing mortality at age for a prediction with fishing mortality equal to the average for the period 2001-2003 ( $\mathrm{F}_{5-10}=0.56$ ) are given in Table 3.34. This is comparable to the usual prediction input table (Table 3.28). The management option table for the Fleksibest prediction is given in Table 3.35.

The standard and Fleksibest predictions differ in a fundamental way because all input values to the standard prediction (Table 3.28) are independent and can be determined separately. This may lead to internal inconsistencies in the prediction input to the standard prediction. Also, effects of different exploitation levels on weight, maturity and selection at age cannot be accounted for using standard predictions. This may be important for medium-term predictions.

The population parameters at age in the Fleksibest prediction (Table 3.34) is determined by the values of growth, recruitment and fishing mortality chosen, as mentioned in Section 3.10.5. With this method, the values of weight, maturity and fishing mortality at age will be consistent with each other.

### 3.10.5.1 Comments to the prognosis

The prognosis shows that fishing with $\mathrm{F}=0.55$ in 2004 and 2005 will keep the total stock biomass around 1.3 million tonnes in 2005-2006.

### 3.10.6 Reference points related to Fleksibest

In order to use Fleksibest for providing management advice for NEA cod, reference points would need to be calculated. It needs to be outlined how reference points could be calculated using Fleksibest. It should be noted that it is somewhat difficult to extend Fleksibest to the time period when survey data are not available (before 1981). Such an extension will require assumptions about the selection pattern of the various fishing fleets backwards in time.

### 3.11 Comparison of results from XSA and Fleksibest.

### 3.11.1 Comparison of the assessments

The abundance at age in 2003 in the Fleksibest assessment is lower for ages 4-7 and higher for age 3 and age 8 and older compared to the XSA assessment (Table 3.15). The reference F in 2003 estimated by Fleksibest and XSA is quite similar ( 0.50 vs. 0.46 ). The reason for this discrepancy in fishing pattern should be investigated. The spawning stock biomass in 2003 is lower in Fleksibest than in XSA, 483 vs. 648 thousand tonnes. This difference is mainly due to the difference in maturity ogives. Fleksibest predicts the SSB in 2004 to be about the same as in 2003, while XSA predicts a considerable increase. The declining trend in fishing mortality from 2001 to 2003 is much stronger in XSA than in Fleksibest.

### 3.11.2 Comparison of the predictions

The Fleksibest predictions show a less optimistic development of the stock than the XSA predictions.

### 3.12 Evaluation of harvest control rule

### 3.12.1 Introduction

At the $31^{\text {st }}$ meeting of the Joint Russian-Norwegian Fisheries Commission (JRNC) in November 2002, the following decision was made:
"The Parties agreed that the management strategies for cod and haddock should take into account the following:

- conditions for high long-term yield from the stocks
- achievement of year-to-year stability in TACs
- full utilisation of all available information on stock development

On this basis, the Parties determined the following decision rules for setting the annual fishing quota (TAC) for Northeast Arctic cod (NEA cod) from 2004 and onwards:

- estimate the average TAC level for the coming 3 years based on $\boldsymbol{F}_{p a}$. TAC for the next year will be set to this level as a starting value for the 3-year period.
- the year after, the TAC calculation for the next 3 years is repeated based on the updated information about the stock development, however the TAC should not be changed by more than $+/-10 \%$ compared with the previous year's TAC.
- if the spawning stock falls below $\boldsymbol{B}_{p a}$, the Parties should consider a lower TAC than the decision rules would imply.

The Parties agreed on similar decision rules for haddock, based on $\boldsymbol{F}_{p a}$ and $\boldsymbol{B}_{p a}$ for haddock, and with a fluctuation in TAC from year to year of no more than +/-25\% (due to larger stock fluctuations).

The Parties agreed that the working group, which worked out the "Basic Document regarding the main principles and criteria for long term, sustainable management of living marine resources in the Barents and Norwegian Seas" during the following year should illustrate how these decision rules will work. The working group shall, in particular, evaluate what level of percentage change in TAC from year to year will be reasonable to utilise. ""

The evaluation of this agreed management strategy is ToR b) for AFWG this year. The evaluation of the harvest control rule for haddock was postponed.

### 3.12.2 General considerations for evaluation of harvest control rules

Evaluation of harvest control rules (HCRs) is usually done using simulation models for the population(s) in question. The scope, nature and quality standards of simulation models that may be used in order to evaluate HCRs are discussed e.g. by Skagen et al. (2003).

Important issues for evaluation of harvest control rules are:

- Choice of population model
- Inclusion of uncertainty in population model
- Long-term simulations into the future vs. simulations on historical data
- Choice of harvest control rules for use in the evaluation (constant F rules, how to reduce F when $\mathrm{SSB}<\mathbf{B}_{\mathrm{pa}}$, limit on year-to-year variation in catch etc.)
- Performance measures for harvest control rules (yield, stock size, F, probability of $\mathrm{SSB}<\mathbf{B}_{\mathrm{lim}}$, annual variation in catches etc.)

### 3.12.3 Approaches for Harvest control rule evaluation presented to the Working Group

Two WDs addressed this issue: WD3 and WD18.

### 3.12.3.1 Long-term stochastic simulation (WD3)

Bogstad et al. (WD3) describe the status of joint Norwegian-Russian work on evaluation of the proposed harvest control rule for Northeast Arctic cod. A slightly modified version of WD3 is given in Appendix 1. A biologically detailed population model for cod for use in the evaluation is described. In this model, recruitment is modelled using a segmented regression approach, as well as a periodic term and a term including the mean weight of spawning fish.

[^1]Growth and maturation is modelled as density dependent, and cod cannibalism can also be included. Assessment error and uncertainty in the stock/recruitment relationship is included. Catch is implemented by first calculating the catch at age from the perceived stock using the fishing mortality derived from the harvest control rule and the given exploitation pattern. This catch at age is then applied to the actual stock. The general modelling approach taken is the same as described by Skagen et al. (2003). Results of long-term stochastic simulations were not given in WD3, but are given below.

## Software used

The simulations were carried out using the PROST software for stochastic projections (Åsnes, WD5). PROST was especially developed for this purpose because existing software for harvest control rule simulations such as WGMTERM, STPR and CS5 do not incorporate the 3-year averaging process (hereafter called the ' 3 -year-averagerule') for setting TAC given by the agreed decision rule. However, PROST is intended as a general tool for stochastic projections.

## Model description

Several variants of the population model were tried. In all cases, 1000 simulations for the period 2003-2103 were performed and the results for the last 80 years of this period were considered. This is done in order to exclude the effect of the initial values. The stock size for 2003 (initial data) was taken from the 2003 assessment, with a normally distributed CV of 0.25 .

The 'default' model was:

- Density-dependent weight at age in stock (average for 1946-2002 used for age groups where densitydependence was not found)
- Weight at age in catch is a function of weight at age in stock
- Full recruitment model from WD (includes uncertainty)
- Time series (1946-2002) average used for maturation for age groups without density-dependent model
- Cannibalism not modelled directly because stock-recruitment relationship is based on a time series of spawning stock and recruitment (1946-present) where cannibalism is not included.
- Exploitation pattern: 2000-2002 average used for all years, uncertainty in implementation as described above
- Assessment error CV 0.25 , normally distributed. This value is large enough to account for the most extreme assessment error experienced, which is about a factor of 2 both for F and SSB.
- No uncertainty in weight at age, maturity at age or natural mortality at age

## Reality check of model

In order to do a reality check of the 'default' model, a run was made with $\mathrm{F}_{5-10}=0.65$, "flat" harvest control rule (see below), $50 \%$ maximum year-to-year-change in TAC and no assessment error. $\mathrm{F}_{5-10}=0.65$ is equal to the average fishing mortality for the period 1946-2002. The average stock size, catch and recruitment for this run are shown in the text table below, together with the average values for 1946-2002 from the 2003 assessment. The values from the simulation are somewhat above the historic average, but they indicate that the model performs reasonably well at this level of fishing mortality. It should be noted that the historic exploitation pattern would give a lower yield than the present exploitation pattern, which is used in the simulations. At lower F levels, such as $\mathrm{F}=0.4$, the model results may be somewhat optimistic because cannibalism is not explicitly modeled and cannibalism tends to increase with increasing stock size.

|  | $\mathrm{F}_{5-10}$ | Recruitment <br> $($ million $)$ | TSB <br> $(1000 \mathrm{t})$ | SSB <br> $(1000 \mathrm{t})$ | Catch <br> $(1000 \mathrm{t})$ |
| :--- | :--- | :--- | :--- | :--- | :--- |
| VPA average <br> $1946-2002$ | 0.65 | 578 | 2015 | 663 |  |
| Simulation result | 0.65 | 590 | 2339 | 460 | 762 |

The density-dependent maturation described in WD3 gave unrealistic results when combined with the 'mean weight of spawners' term in the stock-recruitment function. The reason for this was that high stock biomass caused late maturation and high average weight of spawners. This led to increased recruitment and thus caused the stock to increase way above observed levels. It was thus decided to leave out the density-dependent maturation. The relationship between weight at age and maturity at age is different for the periods 1946-1979 and 1985-2001 (Section 1.4.2.2) and this may
be related to this modelling problem since the maturation model in WD3 was fit to data for the whole time series 19462002.

## Harvest control rules

Let $y$ denote the year for which the quota is to be set. Let the term " 3 -year rule ( $\mathrm{F} 1, \mathrm{x}$ )" denote applying the 3-year average rule described above with $\mathrm{F}_{5-10}=\mathrm{F} 1$ and an $\mathrm{x} \%$ limit on year-to-year changes in TAC. The limit on increase of TAC from year to year could be set different from the limit on decrease from year to year, but such asymmetric rules were not tested. It is assumed that $\operatorname{SSB}(\mathrm{y})$ is not affected by $\mathrm{F}(\mathrm{y})$, which is in line with the current settings used by AFWG (the proportion of F and M before spawning is set to 0 ).

The rules tested were

1. ("linear")
$\mathrm{F}(\mathrm{y})$ set by 3-year rule(F1, 10) if $\operatorname{SSB}(\mathrm{y})>\mathbf{B}_{\mathrm{pa}}$ and $\operatorname{SSB}(\mathrm{y}-1)>\mathbf{B}_{\mathrm{pa}}$
$\mathrm{F}(\mathrm{y})$ set by 3-year rule(F1, unconstrained) if $\mathrm{SSB}(\mathrm{y})>\mathbf{B}_{\mathrm{pa}}$ and $\mathrm{SSB}(\mathrm{y}-1)<\mathbf{B}_{\mathrm{pa}}$
$\mathrm{F}(\mathrm{y})$ set by 3-year rule $\left(F 1 \frac{S S B(y)-B_{\mathrm{lim}}}{B_{p a}-B_{\mathrm{lim}}}\right.$, unconstrained) $\quad$ if $\mathbf{B}_{\mathrm{lim}}<\mathrm{SSB}(\mathrm{y})<\mathbf{B}_{\mathrm{pa}}$
$F(y)=0$
if $\operatorname{SSB}(\mathrm{y})<\mathbf{B}_{\mathrm{lim}}$

Thus, when SSB increases from below $\mathbf{B}_{\mathrm{pa}}$ in year $y-1$ to above $\mathbf{B}_{\mathrm{pa}}$ in year $y$, the TAC in year $y$ should not be calculated using the limit on year-to-year variations in TAC.
2. ("flat")
$\mathrm{F}(\mathrm{y})$ set by 3-year rule(F1, 10)

$$
\text { if } \operatorname{SSB}(\mathrm{y})>\mathbf{B}_{\mathrm{pa}}
$$

$\mathrm{F}(\mathrm{y})$ set by 3-year rule( F 1 , unconstrained)

$$
\begin{aligned}
& \text { if } \operatorname{SSB}(\mathrm{y})>\mathbf{B}_{\mathrm{pa}} \text { and } \operatorname{SSB}(\mathrm{y}-1)<\mathbf{B}_{\mathrm{pa}} \\
& \text { if } \operatorname{SSB}(\mathrm{y})<\mathbf{B}_{\mathrm{pa}}
\end{aligned}
$$

## Results

The results are shown in Table 3.36 and some key results are also shown in the text table below. The figures given in Table 3.36 are average values over all simulations for the years 2024-2103. In addition, the probability of $\mathrm{SSB}<\mathbf{B}_{\lim }$ in any year in the period 2024-2103 during a simulation is given.

The average catch obtained from the 'default' run (Run 1) with F1 $=0.40$ was about 900 thousand tonnes, with an average total stock of 3.5 million tonnes and an average spawning stock of 1.0 million tonnes. The probability of $\mathrm{SSB}<$ $\mathbf{B}_{\mathrm{lim}}$ was negligible in all cases, while the probability of $\mathrm{SSB}<\mathbf{B}_{\mathrm{pa}}$ was $<0.01$. The effect of the following changes from the default model was found to be small at this level of fishing mortality:

- Using a fixed F1 of 0.40 instead of the 3-year rule (Run 2)
- Using the 'flat' rule instead of the 'linear' rule when $\mathrm{SSB}<\mathbf{B}_{\mathrm{pa}}$ (Run 3)
- Increasing the maximum change from year to year to $20 \%, 30 \%$ or $40 \%$ (Run 4-6)
- Increasing the CV (on log scale) for the assessment error from 0.25 to 0.35 (Run 7)

In order to illustrate the possible effects of cannibalism, a run was made (Run 8) where the natural mortality on ages 3 and 4 was set close to the highest values observed in the period 1984-2002, i. e. 0.7 for age 3 and 0.4 for age 4 . This is likely to be an overestimate of the effect of cannibalism. This run gave an average total stock of 2.1 million, an average
spawning stock of 600 thousand tonnes and average catches of 500 thousand tonnes. The probability of $\mathrm{SSB}<\mathbf{B}_{\lim }$ remained negligible, while $\mathrm{SSB}<\mathbf{B}_{\mathrm{pa}}$ in $11 \%$ of the years.

PROST does at present not allow for including bias in the assessment. In order to get a coarse estimate of the effect of bias in the assessment, runs with $\mathrm{F}=0.50$ (and assessment error as described above) were made for assessment error (CV) set to 0.25 and 0.35 , as well as with and without high values of natural mortality for age 3 and 4 (Runs 9-12). Increasing F to 0.5 (assuming a $20 \%$ bias in F) while keeping the other default settings (Run 9) gave lower stock levels and catches, but the probability of $\mathrm{SSB}<\mathbf{B}_{\mathrm{lim}}$ in any year of the simulation only increased to about $1 \%$. This was also the case for a similar run with cannibalism (Run 10). Increasing the assessment error to $\mathrm{CV}=0.35$ and keeping high natural mortality on ages 3 and 4 increased the probability of $\mathrm{SSB}<\mathbf{B}_{\text {lim }}$ in any year to $5 \%$ (Run 11). If a fixed $\mathrm{F}=0.50$ is applied to the population model instead of the 3-year average rule, the probability of $\mathrm{SSB}<\mathbf{B}_{\mathrm{lim}}$ in any year of the simulation increases to $16 \%$ (Run 12). However, even for runs $11 \& 12, \mathrm{SSB}<\mathbf{B}_{\mathrm{lim}}$ in $<1 \%$ of all years. It is noteworthy that the 3 -year average rule is considerably more precautionary than a fixed $F$ rule, as seen from runs 11 and 12. It should be noted that the values of $\%$ mean annual change of TAC for runs $10-12$ are strongly influenced by some runs where the TAC is 0 or close to 0 in some years. The values were calculated ignoring runs where TAC was set to 0 in any year.

| Run <br> no | \% annual |  |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  | Catch |  |  | change | \% Years | \% Years |
|  | 1000 | 1000 | 1000 | in TAC | $\mathbf{S S B}<\mathbf{B}_{\text {lim }}$ | $\mathbf{S S B}<\mathbf{B}_{\mathrm{pa}}$ |
|  | tonnes | tonnes | tonnes | (abs. value) |  |  |
| 1 | 885 | 1018 | 3452 | 7.7 | 0.00 | 0.1 |
| 4 | 884 | 1006 | 3433 | 11.0 | 0.00 | 0.0 |
| 5 | 883 | 999 | 3421 | 12.6 | 0.00 | 0.0 |
| 6 | 884 | 996 | 3419 | 13.2 | 0.00 | 0.0 |
| 7 | 891 | 1046 | 3497 | 8.8 | 0.00 | 0.3 |
| 8 | 497 | 581 | 2104 | 15.2 | 0.00 | 13.2 |
| 9 | 832 | 722 | 2899 | 10.6 | 0.01 | 3.6 |
| 12 | 481 | 486 | 1925 | 116.2 | 0.22 | 44.4 |

We conclude that the "linear" harvest control rule given above is precautionary, as the probability of $\mathrm{SSB}<\mathbf{B}_{\mathrm{lim}}$ is low even using a rather conservative population model with large assessment error. Although uncertainty in weight at age and maturity at age is not included, we do not believe that including this would change our results significantly.

### 3.12.3.2 Stochastic simulations based on historical data (WD 18)

## Model description

WD18 describes a simulation model, which is intended for testing and comparison of various harvest control rules for the NEA cod stock. The population model is described by Bulgakova (2003). The model is applied for the period 19812006, and weight-at-age, maturity at age, natural mortality at age and the exploitation pattern is taken from observed values. This allows for reducing the model output uncertainty and for testing model feasibility. The recruitment is described by a Ricker-type function, which depends on spawning biomass, the population fecundity index and on the index of in $\mathbf{F}_{\text {low }}$ of Atlantic waters. The uncertainty in initial stock size and in the stock-recruitment model is taken into consideration, but assessment error is not included. 100 stochastic simulations were run in each case. The model allows for different harvest control rules.

## Harvest control rules

Three versions of the harvest control rule adopted by the JRNC are tested, in addition to the ICES-precautionary approach type scheme adopted by SGBRP.

These four harvest control rules are described in more detail below.

1: ICES-pa type scheme adopted by SGBRP
$\mathrm{F}(\mathrm{y})=\mathrm{F} 1 \quad$ if $\operatorname{SSB}(\mathrm{y})>\mathbf{B}_{\mathrm{pa}}$,
$F(y)=\frac{S S B(y)-B_{\lim }}{B_{p a}-B_{\lim }} F 1 \quad$ if $\mathbf{B}_{\lim }<\operatorname{SSB}(\mathrm{y})<\mathbf{B}_{\mathrm{pa}}$
$\mathrm{F}(\mathrm{y})=0 \quad$ if $\operatorname{SSB}(\mathrm{y})<\boldsymbol{B}_{\text {lim }}$
For this scheme, simulations were made for $\mathrm{F} 1=0.4,0.5,0.6$ and 0.8

2: JRNC-1 scheme
$\mathrm{F}(\mathrm{y})$ set by 3-year rule $(0.40,10) \quad$ if $\operatorname{SSB}(\mathrm{y})>\mathbf{B}_{\text {lim }}$
$\mathrm{F}(\mathrm{y})=0 \quad$ if $\operatorname{SSB}(\mathrm{y})<\mathbf{B}_{\text {lim }}$

No limit on the year-to-year TAC variation in the first year of simulation (1981)
3: JRNC-2 scheme
$\mathrm{F}(\mathrm{y})$ set by 3 -year rule $(0.40,10) \quad$ if $\operatorname{SSB}(\mathrm{y})>\mathbf{B}_{\mathrm{pa}}$
$F(y)=0.40 \frac{\operatorname{SSB}(y)-B_{\text {lim }}}{B_{p a}-B_{\text {lim }}} \quad$ if $\mathbf{B}_{\text {lim }}<\operatorname{SSB}(\mathrm{y})<\mathbf{B}_{\mathrm{pa}}$
$\mathrm{F}(\mathrm{y})=0 \quad$ if $\operatorname{SSB}(\mathrm{y})<\mathbf{B}_{\text {lim }}$
No limit on the year-to-year TAC variation in the first year of simulation (1981)

## 4: JRNC-3 scheme

$\mathrm{F}(\mathrm{y})$ set by 3-year rule $(0.40, \mathrm{x}) \quad$ if $\operatorname{SSB}(\mathrm{y})>\boldsymbol{B}_{\mathrm{pa}}$ and $\operatorname{SSB}(\mathrm{y}-1)>\mathbf{B}_{\mathrm{pa}}$
$\mathrm{F}(\mathrm{y})$ set by 3-year rule(0.40, no limit) if $\mathrm{SSB}(\mathrm{y})>\mathbf{B}_{\mathrm{pa}}$ and $\operatorname{SSB}(\mathrm{y}-1)<\mathbf{B}_{\mathrm{pa}}$
$F(y)=0.40 \frac{\operatorname{SSB}(y)-B_{\lim }}{B_{p a}-B_{\lim }} \quad$ if $\mathbf{B}_{\lim }<\operatorname{SSB}(\mathrm{y})<\mathbf{B}_{\mathrm{pa}}$
$\mathrm{F}(\mathrm{y})=0 \quad$ if $\operatorname{SSB}(\mathrm{y})<\mathbf{B}_{\mathrm{lim}}$

No limit on the year-to-year TAC variation in the first year of simulation (1981).

Thus, when SSB increases from below $\mathbf{B}_{\mathrm{pa}}$ in year $y-1$ to above $\mathbf{B}_{\mathrm{pa}}$ in year $y$, the TAC in year $y$ should not be calculated using the limit on year-to-year variations in TAC. For this scheme, simulations were made with $\mathrm{x}=10, \mathrm{x}=15$ and $\mathrm{x}=20$.

The performance measures for the different HCRs considered were:

- Average catch during the period
- Probability of $\mathrm{SSB}<\mathbf{B}_{\text {lim }}$ or $\mathrm{F}>\mathbf{F}_{\text {lim }}$
- Realised percentage of year-to-year changes in TAC

## Results

The ICES-pa scheme was found to be precautionary also for $\mathrm{F}=0.5-0.6$. It was found that the JRNC-1 rule can cross the precautionary limits and lead to closure of the fishery. The JRNC-2 rule is precautionary but gives too low average catch. The JRNC-3 scheme with a limit of $10 \%$ variation in annual changes gives a $5 \%$ probability of $\mathrm{SSB}<\mathbf{B}_{\text {lim }}$ during the simulation period and a $10 \%$ probability of $\mathrm{F}>\mathbf{F}_{\text {lim }}$ during the simulation period (Fig. 3.19). This crossing of limit
reference points occurs only in two years out of the 25 years in the simulation period. Increasing the limit of annual variation in TAC to $15 \%$ gave a zero probability of $\mathrm{SSB}<\mathbf{B}_{\text {lim }}$ and of $\mathrm{F}>\mathbf{F}_{\text {lim }}$ during the all simulation period. A further increase of this limit did not affect the cod population dynamics. Table 3.37 shows stochastic forecast from the model JRNC-3 described above for the period 2003-2006. Upper panel corresponds to variant where the recruitment model (Bulgakova, 2003) is used for 2004-2006. Lower panel corresponds to a variant where the recruitment is estimated by the RCT3 program. In both cases the risk probability is zero, but it should be pointed out that this is in a situation of rather high SSB levels.

Thus the JRNC-3 rule is considered precautionary (risk probability equals zero), and will decrease the inter-annual changes in TAC without loss of catches.

### 3.12.4 Comparison of the approaches

The only difference between the harvest control rules "linear" described in Section 3.12.2 and JRNC-3 described in Section 3.12.3 is the determination of F when $\mathbf{B}_{\mathrm{lim}}<\mathrm{SSB}(\mathrm{y})<\mathbf{B}_{\mathrm{pa}}$. In the "linear" rule, $\mathrm{F}(\mathrm{y})$ is given by

3-year rule $\left(0.40 \frac{S S B(y)-B_{\lim }}{B_{p a}-B_{\lim }}\right.$, unconstrained) $\quad$ if $\mathbf{B}_{\lim }<\operatorname{SSB}(\mathrm{y})<\mathbf{B}_{\mathrm{pa}}$
while in the JRNC-3 rule, F is given by
$F(y)=0.40 \frac{S S B(y)-B_{\lim }}{B_{p a}-B_{\lim }} \quad$ if $\mathbf{B}_{\lim }<\operatorname{SSB}(\mathrm{y})<\mathbf{B}_{\mathrm{pa}}$

Thus, both rules have no constraints on the year-to-year variation in TAC when $\mathbf{B}_{\mathrm{lim}}<\mathrm{SSB}(\mathrm{y})<\mathbf{B}_{\mathrm{pa}}$. The "linear rule" uses the 3-year rule with an $\mathrm{F}=0.40 \frac{S S B(y)-B_{\lim }}{B_{p a}-B_{\lim }}$ to determine F when $\mathbf{B}_{\mathrm{lim}}<\mathrm{SSB}(\mathrm{y})<\mathbf{B}_{\mathrm{pa}}$, while the JRNC-3 rule in this case uses the same value $\mathrm{F}=0.40 \frac{\operatorname{SSB}(y)-B_{\mathrm{lim}}}{B_{p a}-B_{\mathrm{lim}}}$ exactly, without using a 3-year average. Using the ' 3 -year average rule' for $\mathrm{SSB}>\mathbf{B}_{\mathrm{pa}}$ but switching to a purely F-based strategy when $\mathrm{SSB}<\mathbf{B}_{\mathrm{pa}}$, as in the JRNC-3 rule, will cause TAC as a function of SSB for a given year to be discontinuous at $\mathrm{SSB}=\mathbf{B}_{\mathrm{pa}}$.

Thus, it seems most consistent to use the "linear" rule. However, the difference between the performance of the "linear" rule and the JRNC-3 rule will probably be insignificant.

### 3.12.5 Conclusions

The studies presented indicate that the HCR proposed by the Commission is in agreement with the precautionary approach, provided that the limit on annual change of TAC is not applied for $\operatorname{SSB}<\mathbf{B}_{\mathrm{pa}}$. It has not been thoroughly tested whether it is also a condition that the F is reduced for $\mathrm{SSB}<\mathbf{B}_{\mathrm{pa}}$ for the HCR to be in agreement with the precautionary approach.

The following rule is proposed and considered to be precautionary:
$\mathrm{F}(\mathrm{y})$ set by 3-year rule $(0.40,10) \quad$ if $\operatorname{SSB}(\mathrm{y})>\mathbf{B}_{\mathrm{pa}}$ and $\operatorname{SSB}(\mathrm{y}-1)>\mathbf{B}_{\mathrm{pa}}$
$\mathrm{F}(\mathrm{y})$ set by 3-year rule( 0.40 , unconstrained) if $\mathrm{SSB}(\mathrm{y})>\mathbf{B}_{\mathrm{pa}}$ and $\operatorname{SSB}(\mathrm{y}-1)<\mathbf{B}_{\mathrm{pa}}$
$\mathrm{F}(\mathrm{y})$ set by 3-year rule $\left(0.40 \frac{S S B(y)-B_{\lim }}{B_{p a}-B_{\mathrm{lim}}}\right.$, unconstrained) if $\mathbf{B}_{\mathrm{lim}}<\mathrm{SSB}(\mathrm{y})<\mathbf{B}_{\mathrm{pa}}$
$F(y)=0$

$$
\text { if } \operatorname{SSB}(\mathrm{y})<\mathbf{B}_{\lim }
$$

This harvest control rule also applies for a rebuilding situation.

Since the $10 \%$-rule is found precautionary, also less restrictive rules (higher than $10 \%$ change) for allowed changes in TAC from year to year will be, since this allows for a more rapid action in case the stock is decreasing.

### 3.12.6 Further work on management strategies for NEA cod

The $32^{\text {nd }}$ meeting of the Joint Norwegian-Russian Fisheries Commission requested an analysis of maximum long-time yield from the most important commercial species in the Barents Sea, based on existing knowledge. The starting point shall be the dynamics of the Northeast arctic cod and account should be taken of the interactions between cod and other species that influence the yield of cod. The work shall be supplied with investigation of other species in this prioritised sequence: capelin, herring, harp seal, minke whales, shrimp and haddock. The investigation shall include all ecosystem elements that are available for investigations, including natural and human-generated effects on reproduction, growth and mortality. The models shall be validated against historic stock developments. The investigation shall also specify further research that can give more precise answers to these questions.

A time schedule for this work is under preparation. This work will be done by Norwegian and Russian scientists, and will build upon the work on management strategies presented here.

The relationship between the relative yearly variation of TAC and the variation of the fishable stock is also relevant to the choice of management strategy. There is obviously a trade-off between yield and stability of catches from year to year. This fact is also worth considering when choosing the appropriate level of annual percentage change in TAC in the HCR (Borisov, WD27).

Table 3.7. Recruitment predictions based on survey indices shrunk towards the vpa mean

Analysis by RCT3 ver3.1 of data from file :
rec20041

NORTHEAST ARCTIC COD : recruits as 3 year-olds (inc. data for ages 0,1),,,
Data for 9 surveys over 19 years : 1985 - 2003

Regression type $=$ C
Tapered time weighting applied
power $=3$ over 20 years
Survey weighting not applied

Final estimates shrunk towards mean
Minimum S.E. for any survey taken as . 20
Minimum of 3 points used for regression
Forecast/Hindcast variance correction used.

Yearclass = 1996

Yearclass = 1997

## Table 3.16a. Diagnostics for final XSA.

Lowestoft VPA Version 3,1

```
7/05/2004 14:45
```

Extended Survivors Analysis
Arctic Cod (run: XSAASA01/X01)
CPUE data from file fleet
Catch data for 20 years, 1984 to 2003, Ages 1 to 13,

| Fleet | First | Last | First | Last | Alpha | Beta |
| :--- | ---: | ---: | ---: | ---: | ---: | ---: |
|  | year | year | age | age |  | 0 |
| FLT09: Russian tri | 1994 | 2003 | 9 | 12 | 0 | 0,99 |
| FLT15: NorBarTrS | 1994 | 2003 | 3 | 8 | 1 |  |
| FLT16: NorBarLof) | 1994 | 2003 | 3 | 11 | 0,99 | 1 |
| FLT17: RusSurCai | 1994 | 2003 | 3 | 8 | 0,9 | 1 |

Time series weights :
Tapered time weighting applied
Power = 3 over 10 years

Catchability analysis :
Catchability dependent on stock size for ages < 6
Regression type $=\mathrm{C}$
Minimum of 5 points used for regression
Survivor estimates shrunk to the population mean tor ages < 6

Catchability independent of age for ages $>=10$

Terminal population estimation :
Survivor estimates shrunk towards the mean $F$
of the final 5 years or the 2 oldest ages,
$S, E$, of the mean to which the estimates are shrunk $=1,000$
Minimum standard error for population
estimates derived from each fleet $=, 300$
Prior weighting not applied

Tuning had not converged after 30 iterations

Total absolute residual between iterations 29 and $30=$,00011
Final year F values

Weighted prediction :

| Survivors <br> at end of year |  | Int | Ext | N | Var |
| :--- | ---: | ---: | ---: | ---: | ---: |$\quad$ F

Time series weights :
Tapered time weighting applied
Power $=3$ over 10 years

Catchability analysis :
Catchability dependent on stock size for ages < 6
Regression type = C
Minimum of 5 points used for regression
Survivor estimates shrunk to the population mean for ages < 6

```
Catchability independent of age for ages >= 10
```

Terminal population estimation :
Survivor estimates shrunk towards the mean $F$ of the final 10 years or the 2 oldest ages.
S.E. of the mean to which the estimates are shrunk $=1.000$

Minimum standard error for population estimates derived from each fleet $=$. 300

Prior weighting not applied

Tuning converged after 30 iterations

Table A5. North-east Arctic COD.
Abundance indices (millions) from the Norwegian Bottom Trawl
survey in the Svalbard area in September-October (1983-1994) and July-August (1995-2003).
Swept area estimates of number of fish at each age. Rock-hopper gear.
(1983-1988 back-calculated from bobbins gear). Corrected for length-dependent effective spread of trawl.

Abundance indices (millions) from the Norwegian Bottom Trawl survey in the Svalbard and Barents Sea area in July-August (1995-2002).
Swept area estimates of number of fish at each age. Rock-hopper gear.
This survey covers ICES Division Ila and llb, as well as the north-eastern part of Sub-area I.
The figures given above for the Svalbard area are included in these estimates

| Age |  |  |  |  |  |  |  |  |  |  |

### 4.1 Status of the Fisheries

### 4.1.1 Historical development of the fisheries

Haddock is mainly fished by trawl as a by-catch in the fishery for cod. There is also a directed trawl fishery for haddock and the proportion of total catches taken by this directed fishery varies between years. On average approximately $33 \%$ of the catch is with conventional gears, mostly longline, which in the past was used almost exclusively by Norway. Russian longliners have increased their fishing and their total landings was 2101 t in 2003. Parts of the longline catches are from a directed fishery. National quotas restrict the fishery. In the Norwegian fishery the quotas are set separately for trawl and other gears. The fishery is also regulated by a minimum landing size, a minimum mesh size in trawls and Danish seine, a maximum by-catch of undersized fish, closure of areas with high density/catches of juveniles and other seasonal and areas restrictions.

The exploitation rate of haddock has been variable. The highest fishing mortalities for haddock have occurred at intermediate stock levels and show little relationship with the exploitation rate of cod, in spite of haddock being primarily a by-catch in the cod fishery. The exception is the 1990s when more restrictive quota regulations resulted in a similar pattern in the exploitation rate for both species.

### 4.1.2 Landings prior to 2004 (Tables 4.1-4.3, Figure 4.1A)

Final reported landings in 2002 are 83726 t (Table 4.1), which is close to the figure used in last year's assessment. The provisional landings for 2003 are 96992 t , which is slightly less than the 101000 t landings expected by the Working Group last year. The agreed TAC was 101000 t . Catches increased in subareas I and IIa. The catch by area, broken down by trawl and other gears, is given in Table 4.2. The nominal catch by country is given in Table 4.3. Landings from 2002 and 2003 were revised according to official statistics from ICES or reports given directly to the working group.

### 4.1.3 Expected landings in 2004

The 101000 t TAC agreed for 2003 was not exceeded. ACFM recommended to set a TAC lower than 120000 t for 2004. The agreed TAC for 2004 is 130000 t . The total landing in 2004 is expected to be equal to the agreed TAC.

### 4.2 Status of Research

### 4.2.1 Fishing effort and CPUE (Table 4.2)

After a period of reduced trawl fishery for haddock, it has increased in recent years (Table 4.2). The CPUE series of Norwegian trawl fisheries has previously been updated for tuning of the older ages in the VPA. The basis was the trawl effort in Norwegian statistical areas 03,04 , and 05 , covering the Norwegian coastal banks north of Lofoten. These areas account for approximately $70 \%$ of the Norwegian trawl landings. However, because of the large proportion taken as bycatch it is difficult to estimate the actual trawl effort on haddock. The CPUE series was not used for tuning the XSA in the two previous assessments and the series has not been updated with values for 2002 and 2003.

### 4.2.2 Survey results (Tables B1-B4)

The overall picture seen in the surveys is summarized as follows: the year class 1997 seems to be poor, the 1998, 1999 and the 2001 year classes appear above average. The 2000 and 2003 year classes appear closer to the average, while the 2002 year class seems to be well above average. The numbers of $6+$ appear at low levels. An other important finding common for all 3 surveys are the relatively high indices observed in 2002 relative to the observations in 2001 and 2003. This "year" effect may contribute towards overestimation of the stock size.

## Norwegian bottom trawl and acoustic survey

Norway provided indices from the 2004 Barents Sea bottom trawl and acoustic survey in January-March (Table B1 and B3). There was a reduced coverage of the Barents Sea in 1997-1998, but full coverage since then. Trawl survey indices from 1983 onwards have been recalculated in the same way as for cod (Section 3.2.2). High indices, caused by the good period of recruitment around 1990, can be tracked from year to year in both series and the 1990-year class appears as the strongest for age groups 3-8. The year classes 1998 to 2001 have been observed as stronger than the 1992-1997 year
classes. The 2002 year class has been observed twice and the last observation is around half of the level observed for the 1990 year class at the same age.

## Russian bottom trawl and acoustic survey

Russia provided indices from the 2003 Barents Sea trawl and acoustic survey (Tables B2, B4a, and B4b), which was carried out in October-December. The Russian surveys show the same main trends as the Norwegian survey. From 1995 onwards there has been a substantial change in the method for calculating acoustic indices. The acoustic survey is therefore presented in 2 tables (Table B4a and B4b) for old and new method of calculating indices.

## International 0-group survey

Estimates of the abundance of 0-group haddock from the International 0-group survey are presented in Tables A14 and A15. The indices indicate good recruitment for haddock from 1990 to 1994, average from 1995 to 1997, good in 1998, average in 1999 and good again in 2000 and 2001 and very good in 2002. The 2003 year class appear as the strongest ever in the area based index (Table A14) while the logarithmic index suggests a year class strength above the 2000 and 2001 year classes, but lower than the 2002 year class.

### 4.2.3 Weight-at-age (Tables B5, B6)

Length and weight-at-age from the surveys are given in Tables B5 and B6, respectively. Weights-at-age seems to be somewhat reduced and are very much in line with the weights used in the predictions last year.

### 4.3 Data Used in the Assessment

### 4.3.1 Catch-at-age (Table 4.7)

Age and length compositions of the landings for 2003 were available from Norway and Russia in Subarea I, from Norway, Russia, and Germany in Division IIa and IIb. The catches of the other countries were distributed among ages using the combined Norwegian/Russian age composition in Subarea I and in Division IIb, and the Russian trawl age composition in Division IIa (Table 4.7). The SOP check gave no deviation from the nominal catch of 2003.

### 4.3.2 Weight-at-age (Tables 4.8-4.9, Table B.6)

The mean weights-at-age in the catch (Table 4.8) were calculated as weighted averages of the weights in the catch of Norway and Russia. The weights-at-age in the catch in 2003 are showing a declining tendency for most ages.

Stock weights (Table 4.9) used from 1985 to 2004 are averages of values derived from Russian surveys in autumn (mostly October-December) and Norwegian surveys in January-March the following year (Table B6). These averages are assumed to give representative values for the beginning of the year.

### 4.3.3 Natural mortality (Table 4.10)

Natural mortality (Table 4.10) was set to $0.2+$ mortality from predation by cod (see Section 4.4.1). The proportion of F and M before spawning was set to zero.

### 4.3.4 Maturity-at-age (Table 4.4 and 4.11)

A maturity ogive was available from Russia for the period 1981-2004 (Table 4.4). The ogives for 2001-2003 shows a relatively early maturation compared to the period 1994 to 1998, while the ogive for 2004 indicates a reduction in the proportions mature at age (later spawning). The maturity-at-age series for the whole period 1950-2002 is shown in Table 4.11. The proportions mature for year classes 1989 and 1990 observed in 1994 made "strange jumps" and has been replaced with average proportions observed in 1993 and 1995 for those age groups.

### 4.3.5 Data for tuning (Table 4.12)

The following surveys series (Table 4.12) are included in the data for tuning:

| Name | Place | Season | Age | Year | prior weight |
| :--- | :--- | :--- | :--- | :--- | :--- |
| Russian bottom trawl | Total area | Autumn | $1-7$ | $1983-2003$ | 1 |
| Norwegian bottom trawl | Barents Sea | Winter | $1-8$ | $1982-2003$ | 1 |
| Norwegian acoustic | Barents Sea | Winter | $1-7$ | $1980-2003$ | 1 |

The indices for the 1996 year class were not used for tuning the XSA. See Section 4.4.1 in the 2002 report. Initial inspection of catch curves revealed a very strong year effect in the 1990 Russian BT survey. The working group choose to delete this survey year from this tuning series without further investigations.

### 4.3.6 Recruitment indices (Table 4.5)

The table with recruitment indices (Table 4.5) covers the year classes 1980 and later. The 0 -group index was not used for input to the RCT3. Since the indices of the 1996-year class were removed from the tuning of the XSA, they were also removed from recruitment estimation. See section 4.4.1 in the 2002 report. Similar reasoning led to the removal of the points from the 1990 Russian BT survey.

### 4.3.7 Prediction data (Table 4.19, Table 4.6)

Weights at age and proportions mature at age shows strong cyclic patterns related to periods of good recruitment. The working group believes that the estimated recruitment in the latest years is so high that it will affect growth and maturation processes. The working group therefore decided to use similar trends in weight at age, maturity and natural mortality as has been observed in previous periods following good recruitment. The input data for making the prediction are presented in Table 4.19 (with only minor changes relative to the procedure in last years assessment):

- The estimated recruitment given in Table 4.6.
- The average fishing pattern observed in the 3 last years.
- Observed maturity for 2004, average maturity for the periods 1987-1989 and 1994-1997 (7 years) for 2006 and maturity at age in 2005 as the average between 2004 and 2006
- Weight at age in the stock for 2005 and 2006 was calculated as the average observed in the period 1994-1997. Last years assessment estimated the 2004 stock weights as the average of the 2003 observations and the 2005 estimates. The 2004 estimates were replaced with the 2004 observations (they were very close).
- Weight at age in the catches for 2005 and 2006 was calculated similarly as the weights in stock. 2004 weights were estimated as average between 2003 and 2004.
- Natural mortality for 2005 and 2006 was calculated similar to the maturity in 2006. Natural mortality in 2004 was calculated as the average of the 2003 and 2005 numbers.
- And stock numbers and fishing mortalities from the standard VPA.

### 4.4 Methods Used in the Assessment

### 4.4.1 VPA and tuning (Table 4.10, Table 4.12, Table A16, Figures 4.5-4.8)

The Extended Survivors Analysis (XSA) was used to tune the VPA to the available index series (Table 4.12). The settings used by the AFWG in 2003 were used with the following changes:

- The tuning window was reduced from 20 to 14 years.
- The F shrinkage was giving a weight corresponding to $\mathrm{SE}=0.5$ (changed from 1.0)

Reduction of the tuning window: All the surveys seem to have consistently negative log catchability residuals for the period previous to 1990. The Norwegian BT survey changed gear in 1989 (from bobbins to rockhopper) and even though the previous indices were recalculated using some kind of conversion factor this would introduce more noise (especially for the younger age groups with the highest conversion factor). The Norwegian acoustic survey changed echosounder in 1990 without any calibration between old and new equipment (the new echosounder being the Simrad EK500 with improved bottom detection algorithm). The log catchability residuals from the XSA (see Figures 4.8 and 4.9) tuning are indicative of a trend in catchability even in the 1990 's, but since the working group is using stock dependent catchability estimates up to age 7 a tuning window as low as 10 years would be uncomfortably short for estimating 2 catchability parameters per age group.

Increased F shrinkage: The survey indices of the last years are producing results with conflicting signals. See Figure 4.7 that summarises single fleet runs. The Russian BT survey and Norwegian acoustic survey indicates a much more rapid increase in SSB and reduction in F than the Norwegian BT survey. The Norwegian BT survey is the survey with the highest weight in the tuning (all ages). Due to the strong decreasing trend in F the XSA results are very sensitive to changes in the level of F shrinkage. Due to the conflicting signals and rapid change in F (not corresponding to the observed level of fishing effort) the working group choose a conservative solution with increased shrinkage (producing results more similar to the results indicated in the Norwegian BT survey single fleet run). The observed high indices in 2002 (see 4.2.2) did also contribute towards the WG choice of increased F shrinkage in the tuning.

The estimated consumption of NEA haddock by NEA cod is incorporated into the XSA analysis by first constructing a catch number-at-age matrix, adding the numbers of haddock eaten by cod to the catches for the years where such data are available (1984-2003) (Table A16). The consumption of NEA haddock by NEA cod is given below:

|  | Consumption of Haddock by NEA Cod (millions ) |  |  |  |  |  |
| ---: | ---: | ---: | ---: | ---: | ---: | ---: |
|  | 1 | 2 | 3 | 4 | 5 | 6 |
| 1984 | 980.0 | 14.7 | 0.1 | 0.0 | 0.0 | 0.0 |
| 1985 | 1203.5 | 5.2 | 0.0 | 0.0 | 0.0 | 0.0 |
| 1986 | 563.9 | 244.9 | 168.0 | 0.0 | 0.0 | 0.0 |
| 1987 | 766.7 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 |
| 1988 | 17.1 | 0.5 | 9.1 | 0.0 | 0.2 | 0.0 |
| 1989 | 236.4 | 0.0 | 0.0 | 0.0 | 0.0 | 0.0 |
| 1990 | 142.3 | 36.4 | 3.5 | 0.0 | 0.0 | 0.0 |
| 1991 | 460.5 | 14.4 | 0.0 | 0.0 | 0.0 | 0.0 |
| 1992 | 2114.9 | 151.1 | 1.1 | 0.0 | 0.0 | 0.0 |
| 1993 | 1377.8 | 167.7 | 37.4 | 3.4 | 2.9 | 0.0 |
| 1994 | 1411.1 | 80.9 | 25.1 | 7.8 | 0.9 | 0.0 |
| 1995 | 2902.0 | 164.0 | 12.0 | 30.1 | 30.2 | 0.3 |
| 1996 | 1593.3 | 161.0 | 40.0 | 5.4 | 2.6 | 3.4 |
| 1997 | 904.8 | 35.5 | 25.7 | 1.7 | 0.8 | 0.5 |
| 1998 | 1527.6 | 27.9 | 2.0 | 2.9 | 0.5 | 0.0 |
| 1999 | 921.9 | 23.6 | 0.3 | 0.0 | 0.0 | 0.0 |
| 2000 | 1309.7 | 66.4 | 2.0 | 1.1 | 0.2 | 0.1 |
| 2001 | 610.6 | 55.1 | 4.8 | 0.1 | 0.0 | 0.0 |
| 2002 | 2588.6 | 249.2 | 42.4 | 2.2 | 0.1 | 0.0 |
| 2003 | 3593.9 | 240.5 | 40.5 | 8.7 | 0.6 | 0.0 |

The fishing mortality estimated by this XSA was split into the mortality caused by the fishing fleet (F) and the mortality caused by the cod's predation (M2) according to the ratio of fleet catch and predation "catch". The new natural mortality data set was then prepared by adding 0.2 (M1) to the predation mortality. This new M matrix (Table 4.10) was used in the final XSA. Future work should include the modelling of natural mortalities taking into account the size of the cod stock, the degree of overlap between the cod and haddock stocks and the availability of other prey (mainly capelin).

The retrospective performance of the XSA is illustrated in Figures 4.5 and 4.6.

### 4.4.2 Recruitment (Tables 4.5-4.6)

The recruiting year classes 2001-2003 were estimated using RCT3 (input given in Tables 4.5 and output given in 4.6). The 0 -group index was not used and the indices for the 1996-year class was also removed as were the indices from the Russian 1990 BT survey. The 2003-year class estimate included high weight to "shrinkage" (high weight given to average recruitment). The age 1 indices from both the Norwegian surveys indicated year classes close to the average recruitment.

### 4.5 Results of the Assessment

4.5.1 Fishing mortality and VPA (Tables 4.10, 4.13-4.18 and Figures 4.1A-D, 4.5-4.7)

The tuning diagnostics of the final XSA (predation included) are given in Table 4.13.

Natural mortalities, fishing mortalities, and stock numbers of the final VPA are given in Tables 4.10, 4.14, and 4.15, respectively, while the stock biomass at age and the spawning biomass at age are given in Tables 4.16 and 4.17. A summary of landings, fishing mortality, spawning stock biomass, and recruitment since 1950 is given in Table 4.18 and Figures 4.1A, 4.1B, 4.1C and 4.1D.

This assessment revised the 2002 fishing mortality slightly downwards compared to last assessment. $\mathrm{F}_{4-7}$ indicates a reduced fishing mortality relative to the period 1997-1999.

The most important year class in the fishery in 2001 was the 1996 -year classes contributing to $60 \%$ of total landings. This contribution was reduced to $31 \%$ in 2002 with the younger 1998-year class contributing $42 \%$. The 1998-year class contributes to $52 \%$ of the landings in 2003. Of more concern is the observation that the weight proportion of $6+$ age groups in the landings is as low as $29 \%$ in 2003. (The proportion of $6+$ was as high as $86 \%$ in 1997.)

The spawning stock biomass estimates represented only minor changes relative to last year's assessment (SSB in 20002002). The 1998 year class is making an impact in 2003 and increases the SSB estimate to 125000 t . The observed proportions mature in 2004 shows a reduction relative to the most recent years and this is a factor contributing to the estimated reduction in 2004 down to 117000 t .

### 4.5.2 Recruitment (Tables 4.6, 4.15 and Figure 4.1C)

This year's assessment (Table 4.6, Figure 4.1C) made the following revisions to the estimated year class strength of the recruiting year classes (numbers in millions at age 3). The numbers marked with * are XSA estimates (Table 4.15):

| Year Class | 2002 | 2003 | 2004 |
| :--- | :--- | :--- | :--- |
| 1998 | 265 | $309^{*}$ | $273^{*}$ |
| 1999 | 241 | $330^{*}$ | $280^{*}$ |
| 2000 | 199 | 250 | $187^{*}$ |
| 2001 | 284 | 277 | 239 |
| 2002 |  | 422 | 384 |
| 2003 |  |  | 159 |

The overall picture is towards lower estimates than the previous assessment more in line with the 2002 assessment.

### 4.5.3 Yield per Recruit, SSB per Recruit (Table 4.19-4.20, Figures 4.2-4.3)

Yield and SSB per recruit based on the parameters in Table 4.19 are presented in Table 4.20. $\mathrm{F}_{0.1}$ and $\mathrm{F}_{\text {max }}$ were estimated to 0.18 and 0.7 respectively. A plot of SSB versus recruitment is shown in Figures 4.2-4.3.

### 4.5.4 Catch options for 2003 (Tables 4.19, 4.21-4.22)

The catch in 2003 corresponds to $\mathrm{Fbar}=0.44$ and the estimated spawning stock biomass will be 117000 t in the beginning of 2004. Assuming a status quo F in 2004 the deterministic projection suggests an increase in SSB to 140000 t in the beginning of 2005 (which is well above $\mathbf{B}_{\mathrm{pa}}$ ). Fishing at $\mathbf{F}_{\mathrm{pa}}$ in 2005 corresponds to total landings of 106000 t , with a further strengthening of the SSB into the beginning of 2006 (table 4.21 ). A prediction with single option table is shown in Table 4.22. The input to the prediction is given in Table 4.19.

### 4.6 Biological reference points.

### 4.6.1 Biomass reference points

The biomass reference points adopted by ACFM for this stock are $\mathbf{B}_{\mathrm{lim}}=50,000 \mathrm{t}$ and $\mathbf{B}_{\mathrm{pa}}=80,000 \mathrm{t}$. No revisions to these values were put forward for consideration at this meeting. However, in light of the strong retrospective year-class dependent bias in haddock assessments it appears that the separation between $\mathbf{B}_{\mathrm{lim}}$ and $\mathbf{B}_{\mathrm{pa}}$ is rather small. Therefore, a more conservative level for $\mathbf{B}_{\mathrm{pa}}$ should be investigated. There is also a need to investigate these reference points relative to the agreed 3 year catch rule and the use of these points in this strategy.

### 4.6.2 Fishing mortality reference points (Figure 4.4)

The fishing mortality reference points adopted by ACFM for this stock are $\mathbf{F}_{\lim }=0.49$ and $\mathbf{F}_{\mathrm{pa}}=0.35$. No revisions to these values were put forward for consideration at this meeting either. However, given the concerns noted above a more
conservative level for $\mathbf{F}_{\mathrm{pa}}$ should be investigated. The potential need for a more conservative $\mathrm{F}_{\mathrm{pa}}$ should also be a part of future evaluations of the agreed 3-year catch rule.

### 4.7 Medium-term simulations

In order to give appropriate advice in accordance with a three-year management strategy, there are three aspects that needs to be considered: the quality of forecasts, the level of reference points and an evaluation of specific harvest control rules. The working group had some discussions related to potential input to a medium-term forecast (deterministic or stochastic), but could not draw any conclusion on the quality of the different suggestions. There was no time to evaluate the uncertainty or the interpretive flexibility due to several reasonable choices of input.

The working group has already addressed concerns about the $\mathbf{B}_{\mathbf{p a}}$ not reflecting the uncertainty well enough. We remind that the $\mathbf{B}_{\mathrm{pa}}$ is meant to reflect the uncertainty in short-term forecasts. Alternative reference points taking the even higher uncertainty in medium-term forecasts into account should therefore be explored.

A three-year harvest control rule is yet not evaluated for haddock. When neither the quality of a short-term prediction, relevant reference points nor the harvest control rule are evaluated, the working group considers a medium-term prediction inappropriate. The uncertainty would not be sufficiently reflected and a decision based on a medium-term forecast would therefore not be in accordance with the precautionary approach.

### 4.8 Comments to the assessment and forecasts

These comments relates mainly to uncertainties in assessment and forecasts

| Source of uncertainty | Description | Comments |
| :--- | :--- | :--- |
| Incomplete survey <br> coverage (1) | Since 1997 has all of the surveys used for tuning <br> been affected by an incomplete coverage for some <br> of the years. (Due to Norwegian vessels not been <br> given access to REZ, Russian vessels not been <br> given access to NEZ). | All indices affected have been corrected <br> using a factor based on geographical <br> distributions observed before and after <br> the incomplete coverage. This procedure <br> is likely to introduce increased <br> uncertainty to the indices. |
| Incomplete survey <br> coverage (2) | None of the surveys have a complete coverage of <br> the stock. The proportion of a year class being <br> outside the coverage varies between year classes <br> (see also the WG report from 2002). The most <br> recent "extreme" case is the 1996 year class <br> (deleted from tuning). | May appear as year class dependent <br> changes in survey catchability. |
| Correlated <br> structures error | Year effects in a survey are quite common. 2 of the <br> tuning series are really the output of two different <br> methods used in the same survey (Norwegian BT <br> and acoustic). The year effect introduces correlated <br> errors between the age groups, but in this case also <br> between survey series. | Discarding is known to be a (varying) <br> problem in the longline fisheries related <br> to the abundance of haddock close to, <br> but below the minimum landing size. |
| Discards | The level of discarding is not known. |  |
| Unreported catches | See Introduction (description of unreported <br> landings of cod in 2002 and 2003) | Unreported landings of cod: The <br> estimation suggested that other species <br> was also subject to this activity. Which <br> species and how much is not known. |

The WG believe that the contributions of the sources of error mentioned above may have increased the uncertainty in the assessment and the predictions the last few years.

The short term forecast is very much depending on the estimates of the year class strength of the incoming year classes. The forecast is also quite depending on the maturity at age, natural mortality and weight at age numbers used as input. These parameters are known to vary quite a lot for this stock and we have tried to create a trend towards observations of such parameters made after period of good recruitment (1987-1989 and 1994-1997). This makes the forecast much more conservative than the traditional average over some range of most recent years. But the working group believes this to be a more realistic approach.

### 4.8.1

 Changes from last yearThe following changes was made to the assessment compared to last year:

1) Total landings in 2002 were revised slightly.
2) As in the two previous assessments the tuning data for the 1996 year class was removed.
3) Based on the inspection of catch curves the data from the Russian BT survey in 1990 was not used in tuning.
4) Based on the inspection of Log Catchability Residuals, the working group choose to reduce the tuning window from 20 years to 14 years.
5) Based on the single fleet diagnostics (which showed conflicting signals between the surveys) and the (somewhat unexpected) rapid decline in estimated fishing mortalities the WG decided to change the weight given to $F$ shrinkage from the weight corresponding to $\mathrm{SE}=1.0$ to $\mathrm{SE}=0.5$.

## $4.9 \quad$ Technical minutes from ACFM

We quote: "Catch weights and stock weights-at-age should be re-examined to account for the abrupt change in ages 9 and 10 during the 1980s."

The cause of the abrupt change in these weights is the replacing of missing (not observed) data points with historic data. These historic data (1950-1982) represents the average of observed values from a period with very high weights (the period is unknown to the current WG, but could possibly be found by looking into old WG reports). The problematic (originally missing) values from 1983-1986 have now been replaced with more realistic values derived using average increments of growth along a cohort. The year classes in question was relatively weak and the changes are expected to produce only minor changes to the perception of the stock.

We quote: "The WG should consider modelling natural mortality related to cannibalism to determine a method of predicting an alternative to $M=0.2$ for years prior to 1984 ."

None of the WG members prepared anything for this topic. There was not enough time during the WG to look into this and the WG also recognizes a potential need to model natural mortality from 1984 onwards due to the highly varying estimates and a possible need to "smooth" these.

We quote: "The report should clearly identify which recruitment estimates are results of XSA versus those from the RCT3 model."

Done.

Table 4.1 North-East Arctic HADDOCK. Total nominal catch ( t ) by fishing areas.
(Data provided by Working Group members).

| Year | Sub-area I | Division Ila | Division llb | Total |
| ---: | ---: | ---: | ---: | ---: |
| 1960 | 125,026 | 27,781 | 1,844 | 154,651 |
| 1961 | 165,156 | 25,641 | 2,427 | 193,224 |
| 1962 | 160,561 | 25,125 | 1,723 | 187,408 |
| 1963 | 124,332 | 20,956 | 936 | 146,224 |
| 1964 | 79,262 | 18,784 | 1,112 | 99,158 |
| 1965 | 98,921 | 18,719 | 943 | 118,578 |
| 1966 | 125,009 | 35,143 | 1,626 | 161,778 |
| 1967 | 107,996 | 27,962 | 440 | 136,397 |
| 1968 | 140,970 | 40,031 | 725 | 181,726 |
| 1969 | 89,948 | 40,306 | 566 | 130,820 |
| 1970 | 60,631 | 27,120 | 507 | 88,257 |
| 1971 | 56,989 | 21,453 | 463 | 78,905 |
| 1972 | 221,880 | 42,111 | 2,162 | 266,153 |
| 1973 | 285,644 | 23,506 | 13,077 | 322,226 |
| 1974 | 159,051 | 47,037 | 15,069 | 221,157 |
| 1975 | 121,692 | 44,337 | 9,729 | 175,758 |
| 1976 | 94,054 | 37,562 | 5,648 | 137,264 |
| 1977 | 72,159 | 28,452 | 9,547 | 110,158 |

## Table 4.6

Analysis by RCT3 ver3. 1 of data from file :
t1 96new
NORTHEAST ARCTIC HADDOCK: recruits as 3 year-olds
Data for 8 surveys over 14 years : 1990 - 2003
Regression type $=$ C
Tapered time weighting applied power $=3$ over 20 years Survey weighting not applied Final estimates shrunk towards mean
Minimum S.E. for any survey taken as . 20
Minimum of 3 points used for regression
Forecast/Hindcast variance correction used.
Yearclass = 2000

## Table 4.13

```
Lowestoft VPA Version 3.1
    11/05/2004 10:49
Extended Survivors Analysis
NEA Haddock (Final XSA AFWG04)
CPUE data from file fleet
Catch data for 54 years. 1950 to 2003. Ages 1 to 11.
\begin{tabular}{crrcccrrr} 
Fleet & \multicolumn{2}{c}{ First Last } & First & \multicolumn{2}{c}{ Last } & \multicolumn{2}{c}{ Alpha } & \multicolumn{2}{c}{ Beta } \\
& year & year & age & age & & & \\
FLT01: Russiar & 1990 & 2003 & & 1 & 7 & 0.9 & 1 \\
FLT02: Norwec & 1990 & 2003 & 1 & 7 & 0.99 & 1 \\
FLT04: Norwec & 1990 & 2003 & 1 & 8 & 0.99 & 1
\end{tabular}
```

Time series weights :
Tapered time weighting applied
Power = 3 over 20 years

Catchability analysis :

Catchability dependent on stock size for ages < 7
Regression type $=\mathrm{C}$
Minimum of 5 points used for regression
Survivor estimates shrunk to the population mean for ages $<7$

Catchability independent of age for ages $>=9$

Terminal population estimation :
Survivor estimates shrunk towards the mean F
of the final 5 years or the 3 oldest ages.
S.E. of the mean to which the estimates are shrunk $=.500$

Minimum standard error for population estimates derived from each fleet $=.300$

Prior weighting not applied

Tuning had not converged after 30 iterations

Total absolute residual between iterations
29 and $30=.00021$

Final year $F$ values

Figure 4.5 NEA haddock. Retrospective plots with shrinkage 1.0

NEA Haddock, retrospective SSB

Figure 4.6. NEA haddock. Restrospective plots with shrinkage $\mathbf{0 . 5}$

Figure 4.7. The upper left panel compares single fleet runs to the combined run. (All runs are made with F shrinkage given as much weight as a tuning fleet with $\mathrm{SE}=1.0$.) The sensitivity of the assessment to changes in the F shrinkage is illustrated in the upper right panel. The signals from the different surveys are illustrated also in the bottom left panel (this time without shrinkage).

NEA Haddock, single fleets, no shrinkage

Figure 4.8. NEA Haddock, Log catchability residuals, single fleets, without shrinkage

NEA Haddock, fleets combined, shrinkage: 1

### 5.1 Status of the Fishery

### 5.1.1 Landings prior to 2004 (Tables 5.1-5.2, Figure 5.1)

Landings of saithe were highest in 1970-1976 with an average of $238,000 \mathrm{t}$ and a maximum of $265,000 \mathrm{t}$ in 1970 . This period was followed by a sharp decline to a level of about $160,000 \mathrm{t}$ in the years 1978-1984. Another decline followed and from 1985 to 1991 the landings ranged from 67,000-122,000 t (Table 5.1). An increasing trend was seen after 1990 to $171,348 \mathrm{t}$ in 1996. Since then the annual landings have been between 136,000 and $160,000 \mathrm{t}$.

In spring 2002 ICES advised that the fishing mortality should be below $\mathrm{F}_{\mathrm{p} a}$, corresponding to catch in 2003 of less than $168,000 \mathrm{t}$. Due to the later increased TAC for 2002 Norwegian authorities set the TAC for 2003 to 164,000 t. Provisional figures show that the landings in 2003 were approximately $160,000 \mathrm{t}$, which is slightly below the level expected by the WG last year.

### 5.1.2 Expected landings in 2004

Last year ICES advised that the fishing mortality should be below $\mathrm{F}_{\mathrm{pa}}$, corresponding to catch in 2003 of less than $186,000 \mathrm{t}$. However, in order to stabilise catches and spawning stock development, The Institute of Marine Research, Bergen, Norway, advised a TAC at the 2003 level. Norwegian authorities set the TAC for 2004 to $169,000 \mathrm{t}$. Official landings in 2004 are expected to be around the TAC of $169,000 \mathrm{t}$, not accounting for problems with bycatch and discards of saithe in the cod fishery.

### 5.2 Status of Research

### 5.2.1 Fishing Effort and Catch-per-unit-effort (Tables C1-C2)

In 2001 new trawl CPUE indices by age were estimated. All days with $20 \%$ or more saithe from vessels larger than the median length are include. A yearly index is calculated by first averaging all CPUE observations for each quarter, and then averaging over the year. The CPUE indices are finally splitted on age groups by yearly catch in numbers and weight at age data from the trawl fishery. There has been an increase in the CPUE from 1999 to 2003, when it reached the highest level in the time series going back to 1980. Due to rather large negative log q residuals in the first part of the new time series, only the period after 1993 is used for tuning.

In the purse seine fishery, more than half of the vessels catch less than 100 tonnes per year, and the sum of these catches represents only about $5-10 \%$ of the total purse seine catch. Therefore the number of vessels catching more than 100 tonnes annually seems to be a more representative and stable measure of effort in the purse seine fishery. These numbers are raised to the total purse seine catch. There was an increase in purse seine effort in 2003 due to better availability of schooling saithe (1999-year class) and transfer of quota, allowing for a longer fishing season.

### 5.2.2 Survey results (Tables C3)

Autumn 2003 the saithe- and coastal cod surveys were combined and extended (Berg, Korsbrekke and Mehl, WD 11). However, until a new time series is established, the estimation of abundance indices going into the tuning is done very much in the same way as before and the results should be comparable. The results from the last survey show a lower total index, with fewer age 3, more of age 4 and 5 and the same amount of 6 years and older fish compared to 2002.

### 5.3 Data used in the Assessment

### 5.3.1 Catch numbers at age (Table 5.3)

The age composition of Norwegian landings in 2002 was revised, resulting in only minor changes in the catch numbers-at-age. Age composition data for 2003 was available from Norway, Russia (Sub-area I) and Germany (Division IIA). These countries accounted for $98 \%$ of the landings. Other areas and countries were assumed to have the same age composition as Norwegian trawlers.

### 5.3.2

Constant weight at age values were used for the period 1960-1979. For subsequent years, annual estimates of weight at age in the catches were used. Weight at age in the stock was assumed to be the same as weight at age in the catch. A decrease in individual weight at age from 2002 to 2003 was found for all age groups except age 2, and most pronounced for age groups 8 to $11+$.

### 5.3.3 Natural mortality

A fixed natural mortality of 0.2 was used both in the assessment and the forecast.

### 5.3.4 Maturity at age (Table 5.14)

The same ogive was used for all years.

### 5.3.5 Tuning data (Table 5.5)

The tuning is based on three data series: indices from the Norwegian acoustic survey on saithe, data from the purse seine fishery and a CPUE series from the trawl fisheries (see chapter 5.2.1). The time span in the Norwegian acoustic survey series include data from 1992 - 2003 only because area coverage was extended from 1992 and onwards. Since the 2003 WG age 2 data are not included in the tuning due to large mean s.e. $\log \mathrm{q}$ residuals.

### 5.3.6 Recruitment indices

Reliable recruitment indices are crucial for the predictions. Attempts at establishing year class strength at age 0 or 1 have so far failed. An observer program aimed at establishing a 0 -group index series has started (2000) (Borge and Mehl, WD 21 2002). The accuracy of the recruitment indices varies from year to year according to the extent to which 2 year old saithe (and in some years even 3 year olds) have migrated out from the near coast areas and become available to the acoustic saithe survey on the banks.

### 5.3.7 Prediction data (Table 5.14)

The input data to the predictions based on results from the XSA-analysis are given in Table 5.14. The stock number at age in 2004 was taken from the XSA for age 5 and older. The recruitment at ages 2 and 3 in 2003 (2000 and 2001 year classes) was estimated using RCT3 (Section 5.5.2). The corresponding numbers at age 3 and 4 in 2004 was calculated applying a natural mortality of 0.2 and fishing mortalities according to the catches taken of these year classes. The longterm geometric mean recruitment 1960-1997 (the last year for which the retrospective analyses show some stability in recruitment) of 215 million was used for the 2002 and subsequent year classes. The natural mortality and the maturity ogive are the same as were used in the assessment. For the exploitation pattern the average of 2001-2003 has been used. For weight at age in stock and catch the average of the last three years in the VPA is normally used. However, the estimates of weight-at-age in the catches show a decreasing trend towards 2003, and therefore the 2003 weights at age have been applied in the predictions. The effect is approximately a $10 \%$ decrease in estimated SSB and catch in the short term predictions.

### 5.4 Methods used in the Assessment

### 5.4.1 XSA and tuning (Table 5.6, Figures 5.2A-C, 5.3A-B)

Extended Survivors Analysis (XSA) was used for the assessment with the same settings as last year. Figures 5.2A-C show plots of the tuning indices versus stock numbers from the XSA. The tuning fleet diagnostics are given in Table 5.6. Figure 5.3A shows mean S.E. Log q from single fleet tuning and Fig. 5.3B presents Log q residuals from the combined tuning. There are some rather large residuals and S.E., especially in the purse seine fleet. As mentioned in section 5.11, this will be further analysed in connection with the full assessment in 2005.

### 5.4.2 Recruitment (Tables 5.8, 5.12-5.13 and C.3, Figure 5.1)

Estimates of the recruiting year classes up to the 1999 -year class from the XSA were accepted. Catches of age group 2 have declined to very low levels in recent years except for an increase in 2000, probably due to a strong 1998-year class (Tables 5.3, Table C3). RCT3-runs were therefore conducted to estimate both the 2000- and 2001-year classes, with 2 and 3 year olds from the survey as input for the estimation.

### 5.5.1 Fishing mortalities and VPA (Tables 5.7-5.11, Figures 5.1 and 5.4)

The fishing mortality $\left(\mathrm{F}_{3-6}\right)$ in 2002 was 0.21 , which is just below the value of 0.22 from last year's assessment. Using the RCT3 estimation of the 2000 -year class gives a fishing mortality $\left(\mathrm{F}_{3-6}\right)$ in 2003 of 0.18 , i.e lower than the corresponding figure for 2002 and well below the $\mathrm{F}_{\mathrm{pa}}$ of 0.26 . Fishing mortalities and stock size tend to be over- and underestimated, respectively, in the assessment year as is illustrated by the retrospective plots in Figure 5.4. Retrospective analysis carried out fleet by fleet all showed the same trend (Mehl and Fotland,WD 15 2003).

The XSA-estimates of the 2000-2001 year classes are not considered to be valid and these estimates are therefore put in brackets (Tables 5.8-5.9). The summary table (Table 5.11) presents the recalculated recruitment figures and total biomass. The 1996 year class were well represented in the catches over several years, and appear to be above average in the current assessment, while the 1997-year class seems to be weak and the 1998-year class a little below average. In 2003 the 1999-year class is dominating the catches, especially in the purse seine fishery, and in the present assessment appear to be almost as strong as the 1992-year class.

The total biomass (ages 2+) has been at a stable and high level above the long-term (1960-2003) mean since 1993. Likewise, the SSB has been above the long-term mean since 1996 (Tables 5.9-5.11).

### 5.5.2 Recruitment (Tables 5.12-5.13)

The RCT3 estimate (with 2 year olds as input, Table 5.12) of the 2001-year class is 228 million individuals, while the RCT3 estimate (with 3 year olds as input and back calculating the strength as 2 year olds, Table 5.13) of the 2000-year class gives 231 million individuals. Thus, both year classes are estimated to be slightly above the long term mean. These estimates are strongly weighted towards the mean value of the input XSA-numbers, which due to the short survey time series also contain year classes that are still not converged. The estimates are therefore not much better than the long term average recruitment, but since this is an update assessment, it was decided to still use the RCT3 estimates for ages 2 and 3 in 2003, and the long-term geometric mean of 215 million individuals for the 2002 and subsequent year classes in the predictions.

### 5.6 Reference points

### 5.6.1 Biomass reference points

In 1995 MBAL for Northeast Arctic saithe was set at 170,000 t. (ICES 1996/Assess:4). This was also proposed as a suitable level for $\mathrm{B}_{\mathrm{pa}}$ by The Study Group on the Precautionary Approach to Fisheries Management (SGPAFM, ICES 1998/ACFM:10). Based on a examination of the stock-recruitment plot ACFM reduced the $\mathrm{B}_{\mathrm{pa}}$ to $150,000 \mathrm{t}$ (ICES 1998).

### 5.6.2 Fishing mortality reference points (Tables 5.14, 5.15, Figures 5.1)

Yield and SSB per recruit were based on the parameters in Table 5.14 and are presented in Table 5.15. $\mathrm{F}_{0.1}$ and $\mathrm{F}_{\max }$ were estimated to be 0.12 and 0.29 , respectively, which is higher than the values obtained last year. The plot of SSB versus recruitment is shown in Figure 5.1. The values of $\mathrm{F}_{\text {low }}, \mathrm{F}_{\text {med }}$ and $\mathrm{F}_{\text {high }}$ obtained in 1999 were $0.18,0.34$ and 0.70, respectively, while the values that were recalculated by WG 2002 were $0.11,0.34$ and 0.69 , respectively. ACFM estimated $\mathrm{F}_{\mathrm{pa}}$ using the formula $\mathrm{F}_{\mathrm{pa}}=\mathrm{F}_{\text {lim }} \cdot \mathrm{e}^{-1.645 \sigma}$ with $\sigma=0.3$ giving a $\mathrm{F}_{\mathrm{pa}}=0.26$ based on an estimated $\mathrm{F}_{\mathrm{lim}}=0.45$ (ICES 1998). Since then the fishing pattern has changed due to the introduction of new minimum catch sizes effective 1 March 1999. A revision of the present fishing mortality reference points will be conducted if and when the new regulation has manifested itself in a stable and improved fishing pattern.

### 5.7 Catch options for 2005 (short term predictions) (Table 5.16)

The management option table (Table 5.16) shows that the expected catch of $169,000 \mathrm{t}$ in 2004 will keep the fishing mortality below $\mathrm{F}_{\mathrm{pa}}$. A catch in 2005 corresponding to $\mathrm{F}_{\text {status quo }}$ level of 0.18 will give $160,000 \mathrm{t}$, while the catch corresponding to $\mathrm{F}_{\mathrm{pa}}$ in 2005 is $215,000 \mathrm{t}$. The SSB is expected to increase to $545,000 \mathrm{t}$ in the beginning of 2005, which is well above the prediction made by last year's working group. At $\mathrm{F}_{\text {status quo }} \mathrm{SSB}$ is estimated to remain at this level, while at $F_{p a}$ it will decrease somewhat.

The input data were the same as used for the short-term predictions (Table 5.14). At $\mathrm{F}_{\text {status quo }}$ the catch will decrease to about $150,000 \mathrm{t}$ in 2006-2008, while the SSB will remain at a stable level of about $540,000 \mathrm{t}$. At $\mathrm{F}_{\mathrm{pa}}$ the catch will increase to $215,000 \mathrm{t}$ in 2005, and stay above $160,000 \mathrm{t}$ during the forecast period. At the same fishing mortality the SSB will increase to about $545,000 \mathrm{t}$ in 2005 and decrease to about $400,000 \mathrm{t}$ in 2009. Results from a projection using RISK show the development of SSB and catch fishing at $\mathrm{F}_{\mathrm{sq}}$ and $\mathrm{F}_{\mathrm{pa}}$ (Figure 5.5A-B).

### 5.9 Comparison of this year's assessment with last year's assessment.

The current assessment estimated the total stock and SSB in 2003 to be about 18 and $2 \%$ higher, respectively, than in the previous assessment. The F in 2002 is estimated to be marginally lower than in the previous assessment.

|  | Total stock (2+) by 1 <br> January 2003 | SSB by 1 January 2003 | F3-6 in 2003 | F3-6 in 2002 |
| :---: | :---: | :---: | :---: | :---: |
| WG 2003 | 866212 | 437232 | 0.23 (prediction) | 0.22 |
| WG 2004 | 1021393 | 447940 | 0.18 | 0.21 |

### 5.10 Comments on the assessment and the forecast

The new increased minimum landing size together with growing interest to fish larger saithe will probably improve the exploitation patterns further. Current fishing mortality reference points should be updated accordingly when an improved exploitation pattern are realised, and the retrospective assessment trend can be dealt with in the new estimation framework.

For comparisons, the summary table (Table 5.11) also presents $\mathrm{F}_{477}$ fishing mortalities. For the current fishing pattern, age $4-7$ is probably a more correct reference age group. This will be further investigated and evaluated in connection with the full assessment in 2005.

Prediction of growth has been a small problem in some periods, especially for abundant year classes. Difficulties in estimating initial stock size due to the widely divergent indices of abundance used in the tuning of the XSA is, in addition to recruitment, at present the major problem in the forecast. This may also be the cause for underestimating the stock size in the assessment year. Prediction of catches beyond the TAC year will, to a large extent, be dependent on assumptions of average recruitment.

### 5.11 Response to ACFM technical minutes

The review committee last year recommended that the commercial CPUE series be examined using generalized linear models to remove possible seasonal and vessel effects. The plan is to do this before the full assessment next year. The trawl CPUE series is already to some extent analysed for seasonal and vessel effects. Only vessels larger than the median lengths are now include, and the yearly index is calculated by first averaging all CPUE observations for each quarter, and then averaging over the year. The WG will further investigate the data from purse seine tuning series to clarify the use of this tuning fleet series in the assessment. In general, the working group tends to put greater reliance in the survey, especially for ages 4 and 5 , compared with purse seine commercial CPUEs. The applicability of only using the survey or together with the trawl series will be further investigated.

The review committee further stated that "Use of RCT3 for recruitment predictions may be no better then a geometric mean since RCT3 uses VPA estimates that have not converged." The reviewers suggested that the working group should justify use of the RCT3 model for projections and that the number of years used in GM estimate should be consistent.

The WG agree that the RCT3 estimates are strongly weighted towards the mean value of the input XSA-numbers, which due to the short survey time series also contain year classes that are still not converged. The estimates are therefore not much better than the long-term average recruitment, but since this is an update assessment, it was decided to still use the RCT3 estimates. When the observer time series of 0 -group indices becomes a little longer, alternative recruitment models will be considered. For consistency, the WG used the long-term geometric mean recruitment 19601997 (the last year for which the retrospective analyses show some stability in recruitment) of 215 million for projections.

[^9]${ }^{2}$ Unresolved discrepancy between Norwegian catch by gear figures and the total reported to ICES for these years.
${ }^{3}$ Includes 4,300 tonnes not categorized by gear, proportionally adjusted.
${ }^{4}$ Reduced by 1,200 tonnes not categorized by gear, proportionally adjusted.

Extended Survivors Analysis
North-East Arctic saithe

CPUE data from file fleetnew.dat

Catch data for 44 years. 1960 to 2003. Ages 2 to 11 .

| Fleet | year ${ }^{\text {Fir }}$ | Last year | First age |  | Last age |  | Alpha | Beta |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| FLT08: Norway Purse | 1989 | 2003 |  | 3 |  | 7 | 0 | 1 |
| FLT12: Nor new trawl | 1994 | 2003 |  | 5 |  | 9 | 0 | 1 |
| FLT13: Norway Ac Sur | 1992 | 2003 |  | 3 |  | 6 | 0.75 | 0.85 |

Time series weights :
Tapered time weighting applied
Power = 3 over 20 years

Catchability analysis :
Catchability independent of stock size for all ages
Catchability independent of age for ages $>=8$

Terminal population estimation :
Survivor estimates shrunk towards the mean F of the final 5 years or the 5 oldest ages.
S.E. of the mean to which the estimates are shrunk $=.500$

Minimum standard error for population
estimates derived from each fleet $=.300$

Prior weighting not applied

Tuning converged after 46 iterations

### 6.1 Status of the Fisheries

### 6.1.1 Historical development of the fishery

A description of the historical development of the fishery is found in the Quality handbook for this stock (see Annex "AFWG-S.Mentella").

Since 1 January 2003 the regulations for this stock have been enlarged since from this date all directed trawl fishery for redfish (both $S$. marinus and $S$. mentella) outside the permanently closed areas is forbidden in the Norwegian Economic Zone north of $62^{\circ} \mathrm{N}$ and in the Svalbard area. When fishing for other species it is legal to have up to $20 \%$ redfish (both species together) in round weight as bycatch per haul and on board at any time.

### 6.1.2 Landings prior to 2004 (Tables 6.1-6.4, D1-D2, Figure 6.1)

Nominal catches of S. mentella by country for Sub-areas I and II combined are presented in Table 6.1, and for both redfish species (i.e., S. mentella and S. marinus) in Table D1. The nominal catches by country for Sub-area I and Divisions IIa and IIb are shown in Tables 6.2-6.4. Total international landings in 1965-2003 are also shown in Figure 6.1.

After a continuous decrease in the total landings from $48,727 \mathrm{t}$ in 1991 to a historical low at about 8,000 t in 1996 and 1997. Apart from a temporary increase of $18,434 \mathrm{t}$ in 2001, caused by Norwegian trawlers obtaining very good catch rates along the continental slope outside the closed areas in winter 2001, the catches decreased to $7,022 \mathrm{t}$ in 2002 . Due to stronger regulations enforced in 2003, the total catch further decreased to $2,443 \mathrm{t}$ in 2003.

The redfish population in Sub-area IV (North Sea) is believed to belong to the North-east Arctic stock. Since this area is outside the traditional areas handled by this Working Group, the catches are not included in the assessment. The total redfish landings from Sub-area IV have been $1,000-3,000 \mathrm{t}$ per year, and show a preliminary landing of about $1,000 \mathrm{t}$ in 2003 (Table D2).

### 6.1.3 Expected landings in 2004

There will be no directed fishery for $S$. mentella in 2004, and all the regulations in 2003 will be continued in 2004. Based on the current regulations, and reports from the first months in 2004, the total landings of S. mentella for 2004 are expected to be maximum $\mathbf{3 , 0 0 0} \mathbf{t}$.

### 6.2 Data used in the Assessment

All input data sets were updated up to and including 2003.

### 6.2.1 Fishing effort and catch-per-unit-effort

The former CPUE-series (catch per hour trawling) from Russian BMRT-trawlers fishing in ICES Division IIa in MarchMay 1975-2002, representative for the directed Russian fishery during these years, has been removed from the current report. The reason for this is the stronger regulations enforced on the fishery making the current CPUEs not comparable with previous years.

### 6.2.2 Catch at age (Table 6.5)

Catch at age for 2000 and 2002 were revised according to new catch data. Age data for 2003 for S. mentella were available from Norway for all areas, and from Russia in Division IIb. Russian catch-at-length from Sub-area I and Division IIa were converted to catch-at-age by using the Norwegian age-length key from Sub-area I and Division IIa (northern part), respectively. Other countries were assumed to have the same relative age distribution and mean weight as Norway.

### 6.2.3 Weight at age (Table 6.6)

Catch weight-at-age data for 2003 were available from Norway for all areas, and from Russia in Division IIb. The weight at age in the stock was set equal to the weight at age in the catch. It should be investigated further whether it would be better to
use a constant weight-at-age series (e.g., based on survey information) instead of catch weight-at-age which may vary due to changes and selections in the fisheries and not due to growth changes in the stock.

### 6.2.4 Maturity at age (Table D8)

Age-based maturity ogives for S. mentella (sexes combined) were available for 2000 and 2001 from Russian research vessel observations in spring. For 2002 and 2003, when the Russian research vessel did not get access to the survey area, a weighted (by sample size) average of the 2000 and 2001 data was used.

### 6.2.5 Survey results (Tables A14, D3-D7, Figures 6.2-6.6)

The results from the following research vessel survey series were evaluated by the Working Group:

1) The international 0-group survey in the Svalbard and Barents Sea areas in August-September (Table A14 and Figure 6.2).
2) Russian bottom trawl survey in the Svalbard and Barents Sea areas in October-December from 1978-2003 in fishing depths of 100-900 m (Table D3, Figure 6.3).
3) Norwegian Svalbard (Division IIb) bottom trawl survey (August-September) from 1986-2003 in fishing depths of $100-500 \mathrm{~m}$. Data disaggregated by age only for the years 1992-2003 (Table D4a,b).
4) Norwegian Barents Sea bottom trawl survey (February) from 1986-2004 (joint with Russia since 2000) in fishing depths of 100-500 m. Data disaggregated by age only for the years 1992-2004 (Tables D5a,b).

Although the Norwegian Svalbard (August-September) and Barents Sea (February) groundfish surveys are conducted at different times of the year and may overlap in the south of Bear Island area, the two series can be combined to get an approximate total estimate for the whole area. This has been done in Figures 6.4a,b.
5) A new Norwegian survey designed for redfish and Greenland halibut covers the Norwegian Economic Zone (NEZ) and Svalbard incl. north and east of Spitsbergen in August 1996-2003 from less than 100 m to 500 m depth (Table D6, Figures 6.5-6.6). This survey includes survey no. 3 above.
6) Russian acoustic survey in April-May from 1992-2001 (except 1994 and 1996) on S. mentella spawning grounds in the western Barents Sea (Table D7).

A considerable reduction in the abundance of 0-group redfish has been observed since 1991: abundance decreased to only $20 \%$ of the 1979-1990 average. With the exception of an abundance index of twice the 1991-level in 1994, the indices have remained very low. Record low levels of less than $20 \%$ of the 1991-1995 average have been observed for the 1996-1999 year classes. The 2000 year class was stronger than the preceding four year classes, whereas the estimate of the 2001-2003 year classes are among the lowest on record.

Results from the Norwegian ecosystem survey (Table D6 and Figure 6.5) confirm the stock development as interpreted from the 0-group survey (Figure 6.2), i.e., relative strong 1988-1990 year classes, followed by weaker 1991-1995 year classes, and very weak year classes since 1996 onwards. The survival of the 1991-1995 year classes seems, however, to have been better than for the previous ones, making them more similar in size at an age of 8-9 years and older than could be expected from the 0 -group survey.

In the Russian bottom trawl survey the most recent estimates are among the lowest observed (Table D3, Figure 6.3). The overall picture of the relative strength of the year classes is, however, very similar in the Russian and Norwegian surveys. However, both the Russian survey back to 1977 and results from combining the Norwegian Barents Sea February and the Svalbard August surveys back to 1986 (Figure 6.4) show lower and more variable abundance of S. mentella in the 1980-ies than could be expected from the 0 -group indices and when compared with the abundance observed at present.

The decrease in the abundance of young redfish in the surveys is consistent with the decline in the consumption of redfish by cod from 1995 onwards (Tables 1.3, 1.4).

Russian acoustic surveys estimating the commercial sized and mature part of the $S$. mentella stock have been conducted in April-May on the Malangen, Kopytov, and Bear Island Banks since 1986. Table D7 shows a $43 \%$ decrease in the estimated spawning stock biomass in 1997 to a low level that was observed up to 2000 inclusive. The strong 1982-year class migrating west-southwest and out of the surveyed area could explain this. The next year classes expected to contribute significantly to the spawning stock (i.e., the 1987-1990 year classes) are now more than $50 \%$ mature (males before females), and these year classes contributed in the 2001 survey to a three fold increase in the survey abundance of mature fish (Table D7). This is the only survey targeting commercial sized $S$. mentella, but only a limited area of its distribution. In 2002 and 2003 it was unfortunately impossible to run this survey.

### 6.3 Results of the Assessment

All available information since last year's assessment confirms the poor condition of this stock. The surveys indicate that recruitment continues to decline.

Length and age data from Norwegian and Russian surveys show that the 1982 and 1983 year classes are stronger than those just before and after. The 1988-1990 year classes (possibly also the 1987 year class) appear to be at a similar level to those of 1982-1983. Although at the youngest stages only ca. 20\% of the 1988-1990 year classes' strength, the 1991-1995 year classes seem to have experienced better protection and survival than the former ones. The 0 -group survey indicates at present record low levels of $S$. mentella recruiting to the stock. There is no doubt that the recruitment to the fishable biomass will be poor after a short period of expected increase, or delayed decrease, in the fishable stock due to the 1987-1990 year classes and seemingly better survival of the 1991-1995 year classes than earlier could be expected.

Any improvement of the stock condition is not expected until a significant increase in spawning stock biomass has been detected in surveys with a following increase in the number of juveniles. As long as the recruitment of new year classes is very poor and no signs of improved recruitment have appeared, it is of crucial importance that the 1987-1990 year classes (approx. 34-39 cm) which currently have recruited more than $75 \%$ to the spawning stock are protected.

It is also of vital importance that the younger recruiting year classes be given the strongest possible protection from being taken as by-catch in any fishery, e.g., the shrimp fisheries in the Barents Sea and Svalbard area. This will ensure that they can contribute as much as possible to the stock rebuilding.

### 6.4 Comments to the assessment

The survey series may still be improved further, and it is imperative for good results that valuable research survey time series are continued, and that Norwegian and Russian research vessels get full access to each other's exclusive economic zones. With great restrictions on the S. mentella fishery, it is even more important that surveys are conducted to cover the entire area of this stock's distribution.

### 6.5 Biological reference points

Until an analytical assessment can be accepted and used as basis for reference points calculations, candidate reference points for the biomass or numbers ( $\mathrm{U}_{\mathrm{lim}}$ ) could be set at the average biomass (or number) level, or at a certain percentage of this level, estimated by the Russian and Norwegian trawl surveys since 1986. Such practice is currently used by ICES for the Icelandic redfish stocks (ICES CM 2002/ACFM:20 Ask Kjell) and is a procedure mentioned and recommended as an alternative by the ICES Study Groups on the Precautionary Approach. It is, however, difficult at present to calculate a reasonable level for Ulim from the available survey data due to short survey time series, and the fact that the present surveys started after the stock had already declined for a long time.

### 6.6 Management advice

ICES recommended last year a continuation of the measures introduced in 2003, i.e. that there be no directed trawl fishery on this stock and that the area closures and low bycatch limits should be retained, until a significant increase in the spawning stock biomass (and a subsequent increase in the number of juveniles) has been detected in surveys. In addition, it is of vital importance that the juvenile age classes be given the strongest protection from being caught as bycatch in any fishery, i.e. the shrimp fisheries in the Barents Sea and Svalbard area. This will ensure that the recruiting year classes can contribute as much as possible to the stock rebuilding.

The by-catch of redfish in other fisheries should be reduced to the lowest possible level. The current assessment indicates no improvement in recruitment while a stabilizing or temporary increase of the SSB is expected if the catches are kept low.

As long as the recruitment of new year classes is very poor and no signs of improved recruitment have appeared, it is of crucial importance and urgent that the 1987-1990 year classes (approx. 34-39 cm) which currently have recruited more than $75 \%$ to the spawning stock are protected. The Working Group is therefore satisfied with the stronger regulations enforced in the trawl fisheries from 1 January 2003 onwards. It is also of vital importance that the younger recruiting year classes be given the strongest possible protection to ensure that they can contribute as much as possible to the stock rebuilding.

Given the current depleted state of the stock and less data from the fishery, it is imperative that data collection and survey time series be maintained and improved in order to monitor the development and rebuilding of the resource.

### 6.7 Response to ACFM technical minutes

ACFM recommends that other analytical methods involving survey and/or length data should be explored. Possible alternative methods to conventional catch-at-age analyses, such as the FLEKSIBEST model, have been discussed but not yet explored for this redfish stock. This model is closely related to the BORMICON model which currently is used by the ICES North-Western WG on S. marinus (Björnsson and Sigurdsson 2003). As for S. marinus, possible alternative methods may also be found in assessments of Sebastes stocks in the eastern North Pacific (e.g Methot). During the Working Group the survey based model SURBA was presented, and this may be a useful tool for improved evaluation and estimation of the redfish stocks from survey results (Needle 2003, 2004).

Table 6.1. Sebastes mentella in Sub-areas I and II, Total international landings 1965-2003 (thousand tonnes).

Figure 6.2. Abundance indices of 0 -group redfish (believed to be mostly S.mentella ) in the international 0 -group survey in the Barents Sea and Svalbard areas in AugustSeptember 1980-2003.

Figure 6.3. Catch (numbers of specimens) per hour trawling of different ages of Sebastes mentella in the Russian groundfish survey in the Barents Sea and Svalbard areas (ref. Table D4).

Figure 6.4a. Sebastes mentella. Abundance indices (on length) when combining the Norwegian bottom trawl surveys 1986-2003 at Svalbard (summer/fall) and in the Barents Sea (winter).

Figure 6.4b. Sebastes mentella. Abundance indices (on age) when combining the Norwegian bottom trawl surveys 1992-2003 at Svalbard (summer/fall) and in the Barents Sea (winter).

Figure 6.5. Survey regions and subareas in the new Norwegian ecosystem survey in the Barents Sea and adjacent areas in August-September 1996-2003 covered by the standard 1800 Campelen research trawl shallower than ca. 500 m . Subareas 1-10 are further depth stratified. The Svalbard region comprises these ten subareas, while the Barents Sea region comprises subareas 11-16, excl. the Russian Economic Zone. In addition to the areas shown on the map comes the area north and east of Spitsbergen which is also included in the survey estimate (ref. Table 6.5).

Figure 6.6. Sebastes mentella . Abundance indices (on age) from the new Norwegian demersal fish survey in August-September 1996-2003 covering the Norwegian Economic Zone (NEZ) and Svalbard incl. the area north and east of Spitsbergen (ref. Table D6).

Table D1 REDFISH in Sub-areas I and II. Nominal catch (t) by countries in Sub-area I, Divisions IIa and IIb combined as officially reported to ICES.

### 7.1 Status of the Fisheries

### 7.1.1 Historical development of the fishery

A description of the historical development of the fishery is found in the Quality handbook for this stock (see Annex afwg-smr).

Until 1 January 2003 there were no regulations particularly for the $S$. marinus fishery, and the regulations aimed at $S$. mentella (see chapter 6.1.1) had only marginal effects on the S. marinus stock. After this date, all directed trawl fishery for redfish (both $S$. marinus and $S$. mentella) outside the permanently closed areas have been forbidden in the Norwegian Economic Zone north of $62^{\circ} \mathrm{N}$ and in the Svalbard area. When fishing for other species it is legal to have up to $20 \%$ redfish (both species together) in round weight as bycatch per haul and on board at any time. Until 14 April 2004 there were no regulations of the other gears/fleets fishing for $S$. marinus. After this date, a minimum legal catch size of 32 cm has been set for all fisheries, with the allowance to have up to $10 \%$ undersized (i.e., less than 32 cm ) specimens of S.marinus (in numbers) per haul. In addition, a limited moratorium during 1-31 May has been enforced in all fisheries except trawl. When fishing for other species (also during the moratorium) it is allowed to have up to $20 \%$ bycatch of redfish (in round weight) summarized during a week fishery from Monday to Sunday. Furthermore, after 1 January 2006 it will be forbidden to use gillnets with meshsize less than 120 mm when fishing for redfish.

### 7.1.2 Landings prior to 2004 (Tables 7.1-7.5, D1 and D2, Figure 7.1)

Nominal catches of S. marinus by country for Sub-areas I and II combined are presented in Table 7.1 and the totals for both S. marinus and S. mentella in Tables D1 and D2. Landings of S. marinus showed a decrease in 1991 from a level of 23,000$30,000 \mathrm{t}$ in 1984-1990 to a stable level of about $16,000-19,000 \mathrm{t}$ in the years 1991-1999. Since then the landings have decreased further, and the provisional total landings figure for $S$. marinus in 2003 of $7,849 \mathrm{t}$ is the lowest since the mid1940ies (!). The Norwegian landings are presented by gear and month in Figure 7.1.

Information describing the splitting of the redfish landings by species and area is given in the Quality handbook. The time series of S. marinus landings are given in Table 7.5 and shows a long-term (1908-2003) mean of 17,344 t.

### 7.1.3 Expected landings in 2004

On the basis of reports from the first months of the year, a legal by-catch of $20 \%$ in any trawl fishery, and an assumed minor effect of the regulations for the other gears, the Norwegian landings in 2004 are not expected to decrease by more than about $1,000 \mathrm{t}$ compared to 2003 , leading to a total Norwegian catch of about $6,000 \mathrm{t}$. The Russian catch is expected to be 400 t . On this basis landings of $\mathbf{6 , 8 0 0} \mathbf{t}$ are expected in 2004.

### 7.2 Data Used in the Assessment

### 7.2.1 Fishing effort and catch-per-unit-effort (Tables D9, Figure 7.2)

The former CPUE-series for S. marinus from Norwegian 32-50 meter freezer trawlers was improved (e.g., analysing the trawl data with regards to vessel length instead of vessel tonnage) and presented from 1992 onwards (Table D9). Only data from days with more than $10 \%$ S. marinus in the catches (in weight) were included in the annual averages. The sensitivity/consequences of using different percentages should be further investigated, though the present $20 \%$ bycatch regulation puts limitations on what's possible to use. Mean CPUEs with standard errors together with number of vessel days meeting the $10 \%$ criterion are presented in Table D9 and Figure 7.2.

Although the trawl fishery until 2003 was almost unregulated, the trawlers experienced fewer and fewer fishing days with more than $10 \%$ of their catches composed of S. marinus. From 1996 until 2001, Figure 7.2 shows an inverse correlation between catch-rates and number of vessel-days. Since 2001, however, both the catch-rates and the number of vessel-days are decreasing, and this is worrying despite the fact that $S$. marinus since 2003, due to regulations, should not compose more than maximum $20 \%$ of the catch in each trawl haul. With some variation, the average annual catchrates have decreased from an average level of $350 \mathrm{~kg} /$ trawlhour during mid 1990ies to a provisional figure of $136 \mathrm{~kg} / \mathrm{h}$ in 2003, i.e., less than $40 \%$ of the former recent level.

Catch at age data for 2000, and 2002-2003 were revised. Age composition data for 2003 were only provided by Norway, accounting for $89 \%$ of the total landings. Russian catch-at-length from each Sub-area were converted to catch-at-age by using the Norwegian age-length keys in Subarea I, Divisions IIa (northern part) and IIb, respectively. Other countries were assumed to have the same relative age distribution and mean weight as Norway. The updated catch-in-numbers at age matrix is shown in Table 7.6.

### 7.2.2 Weight at Age (Table 7.7).

Weight-at-age data for ages 7-24+ were available from the Norwegian landings in 2003.

### 7.2.3 Maturity at age

A maturity ogive was not available for $S$. marinus, and knife-edge maturity at age 15 is assumed.

### 7.2.4 Survey results (Tables D10a,b-D11a,b-D12, Figures 7.3a,b-7.4a,b)

The results from the following research vessel survey series were evaluated by the Working Group:

1) Norwegian Barents Sea bottom trawl survey (February) from 1986-2004 (joint with Russia since 2000) in fishing depths of 100-500 m. Length compositions for the years 1986-2004 are shown in Table D10a and Fig 7.3a. Age compositions for the years 1992-2004 are shown in Table D10b and Figure 7.3b. This survey covers important nursery areas for the stock
2) Norwegian Svalbard (Division IIb) bottom trawl survey (August-September) from 1985-2003 in fishing depths of 100-500 m. Length compositions for the years 1985-2003 and age compositions for the years 1992-2003 are shown in Table D11a and D11b, respectively. This survey covers the northernmost part of the species' distribution.

Data on length and age from both these surveys have been combined and are shown in Figures 7.4a,b.
3) Catch rates (numbers/nautical mile averaged for all stations within subareas and finally averaged, weighted by subarea, for the total surveyed area) of Sebastes marinus from the Norwegian Coastal and Fjord survey in 19952003 from Finnmark to Møre (Table D12).

The bottom trawl surveys covering the Barents Sea and the Svalbard areas show that the abundance indices over the commercial size range ( $>25 \mathrm{~cm}$ ) were relatively stable up to 1998. Since then the abundance has decreased. In addition, fewer pre-recruit sized fish $(<25 \mathrm{~cm})$ will lead to poorer recruitment to the fishable biomass.

Results from the Norwegian Coastal and Fjord survey confirm poor recruitment and also show an overall reduction in the abundance of this species irrespective of fish size (except for fish $>35 \mathrm{~cm}$ ). Some variation in the results from year to year may be due to a variable number of trawl stations taken in some of the areas from year to year, and annual variations in local fish migrations (Table D12).

### 7.3 Results of the Assessment

The current assessment is an update of last year's assessment with a minor improvement of the commercial CPUE series. All present available information confirms last years' evaluation of stock status.

The current assessment raises great concern about the stock. Data from both the scientific surveys and commercial CPUE show a very disturbing reduction in fishable biomass. The survey covering the near-coast and fjord resources show an overall reduction in abundance from 1995 to 2003 for sizes less than 35 cm . Concerns are again expressed about the low number of pre-recruit size groups in all the recent surveys suggesting that future recruitment to the fishery may be poor. Further declines in the stock can therefore be expected in the near future.

Candidate limit reference point for the biomass or numbers (Ulim) could be set at the average biomass (or number) level of $S$. marinus above 25 cm , or at a certain percentage of this level, estimated by the Norwegian trawl surveys for the time period 1986-1997. Such practice is currently used by ICES for the Icelandic redfish stocks (ICES CM 2003/ACFM:23) and is a procedure mentioned and recommended as an alternative by the ICES Study Groups on the Precautionary Approach. The Working Group proposes such a Ulim to be set at 41 mill. specimens above 25 cm corresponding to the average number of the five lowest survey abundance estimates during 1986-1997, and Upa to be set at 64 mill. specimens above 25 cm which corresponds to $80 \%$ of the three highest survey trawl indices in the combined February Barents Sea survey and the August Svalbard summer survey during 1986-1997 (Tables D10a, D11a, Figure 7.4a). These survey series are at present only available by numbers.

The stock is expected to continue to decline over the next several years as a series of poor year-classes will recruit to the fishery. Consistent with a precautionary approach, ICES recommends that a management plan, including monitoring of the development of the stock and of the fishery, based on legal obligations, should be further developed.

Such a plan may consider stronger bycatch regimes, restricted fishing periods, closure of areas and TAC. The Working Group is confident with the new regulations enforced in 2003 and 2004, but re-iterates the need for a management plan and strategy for how and how fast the rebuilding should be.

The Working Group evaluated the recently enforced regulations of both the trawl fishery and the conventional gears, of which gillnets impose the greatest impact on the stock. Data available to the Working Group show that the trawl catches went down from $4,009 \mathrm{t}$ in 2002 to 2,241 in 2003, i.e., $55 \%$ of the 2002 level. The limited moratorium is at the best expected to reduce the annual catch by ca. 800 t , or to $\mathrm{ca} .85 \%$ of the 2003 catch taken by other gears than trawl.

The Norwegian combined Barents Sea and Svalbard surveys show a decrease in numbers of $S$. marinus above 25 cm to ca. $35 \%$ of the average of the five lowest survey indices in 1986-1997 (the level proposed as Ulim). In addition, the trawl CPUE series shows a decrease to a present level that is less than $40 \%$ of the average 1992-1996 level. Much stronger regulations than those recently enforced are therefore needed. Continuing using moratorium that allows for $20 \%$ bycatch as the regulation measure, at least $4-5$ of the best fishing months needs to be included to obtain the necessary effect. In addition, further improvement of the trawl bycatch regulations should also be considered.

### 7.5 Response to ACFM technical minutes

S. marinus is considered to be an easier species to age than $S$. mentella, and it is possible to follow year classes through the input survey data series. An annual updated database on catch-in-numbers at age and length, weight-at-age, and trawl survey indices both by length and age should be continued to be used in future alternative assessment methods. Possible alternative methods to conventional catch-at-age analyses, such as the FLEKSIBEST model, have been discussed but not yet explored for this redfish stock. This model is closely related to the BORMICON model which currently is used by the ICES North-Western WG on S. marinus (Björnsson and Sigurdsson 2003). ACFM recommends the Working Group to investigate other alternative methods which may be found in assessments of Sebastes stocks in the eastern North Pacific (e.g Methot). Additional effort should be made to consider survey and length-based models, and explore alternative methods for estimating uncertainty around CPUE and survey time-series (e.g. jack-knife or bootstrap methods). The Working Group will follow up on this recommendation and conduct preparatory international work to explore this. During the Working Group the survey based model SURBA was presented, and this may be a useful tool for improved evaluation and estimation of the $S$. marinus stock from survey results (Needle 2003, 2004).

### 8.1 Status of the fisheries

### 8.1.1 Landings prior to 2003 (Tables 8.1-8.5, E10)

Nominal catches by country for Subareas I and II combined are presented in Table 8.1. Tables $8.2-8.4$ give the catches for Subarea I and Divisions IIa and IIb separately. For most countries the catches listed in the tables are similar to those officially reported to ICES. Some of the values in the tables vary slightly from the official statistics, and represents those presented to the Working Group by the members. The tables also incorporate data presented to the Working Group on Spanish survey catches. Landings separated by gear type are presented in Table 8.5.

The revised total catch for 2002 is $13,161 \mathrm{t}$, which is 21 t more than used in the previous assessment. The preliminary estimate of the total catch for 2003 is $13,002 \mathrm{t}$. This is about $2,000 \mathrm{t}$ below the projected catch for 2003 estimated by the Working Group during its 2003 meeting.

In recent years, some fishing for Greenland halibut has taken place in the northern part of Division IVa. In the period 1973-1990, the annual catch in Division IVa was usually well below 100 t , occasionally reaching 200 t . Since then, catches increased sharply from 558 t in 1991 to $2,010 \mathrm{t}$ in 1996 (Table E10). Catches remained comparatively high until they dropped to below 900 t in 2000. The increase from 1973 to 1991 was due mainly to a gillnet fishery. In recent years most of the catch has been taken by trawl. This fishery is in another management area and is not restricted by any TAC regulations. Although there is a continuous distribution of this species from the southern part of Division IIa along the continental slope towards the Shetland area, little is known about the stock structure and the catch taken from this area has therefore not been added to the catch from Subareas I and II.

Around Jan Mayen, small catches of Greenland halibut have been taken in some years. In the period 1992-97 the reported annual catches were $56 \mathrm{t}, 0,140 \mathrm{t}, 270 \mathrm{t}, 59 \mathrm{t}$, and 54 t respectively. In the period $1998-1999$ no catches were reported from this area. In the period $2000-2003$ catches in this area were around 60 t or lower. Jan Mayen is within Subarea IIa, but little is known about the relationship with the stock assessed by the Arctic Fisheries Working Group. Catches from this area have therefore not been included in the catches given for Subarea II.

### 8.1.2 Expected landings in 2004

The fishery for Greenland halibut is regulated by quotas that should be taken by gillnetters and longliners within a restricted time period, and by restricting allowed bycatch in the trawl fishery. The total Norwegian catch in 2004 is expected to be $9,100 \mathrm{t}$. In addition $4,400 \mathrm{t}$ is expected to be caught by Russian vessels and 500 t by other countries. Expected total landings (officially) for 2004 are thus $14,000 \mathrm{t}$. It is believed that there may be additional landings that are not reported.

The catches from Division IVa are expected to be maintained at the same level as last year.

### 8.2 Status of research

### 8.2.1 $\quad$ Survey results (Tables A14, E1-E8)

Over the last several years the Working Group has been concerned about trends in catchability within individual surveys used for tuning of the XSA. The trends were seen for younger ages of year classes in the late 80 's and early 90 's that were initially estimated very low in abundance. With increasing age these year classes were estimated much closer to the mean abundance. In previous meetings the Working Group therefore increased the lower age used in tuning to five years in order to reduce the problem. This only partly solved the problem though, and in all subsequent assessments estimated recruitment of the last 2-3 years has increased from one year to the next.

Most of the surveys considered by the Working Group in 2003 cover either the adult population in the slope area or juvenile distribution in northern areas. The problem of underestimation of recruitment in the last few years included in the analyses has been attributed to shortcomings in survey coverage. The Working Group has at previous meetings noted the need for annual surveys that sample most of the population within a short period of time. Prior to the 2002 WG meeting effort was therefore made to combine some of these surveys into a new total index. The new index is termed the Norwegian Combined Survey Index and is established back to 1996, the first year with survey coverage northeast of Svalbard. It includes bottom trawls from the Norwegian bottom trawl survey in August in the Barents Sea and Svalbard (Tables E1 and E2), the Norwegian Greenland halibut survey in August along the continental slope (Table E3), and the Norwegian bottom trawl
survey in August-September north and east of Svalbard (Table E4). Prior to the meeting in 2003 work was done to evaluate the combination of these survey series into one index and this was reported to the Working Group (Pennington, WD 5\#2003). Based on these results it was decided to use the combined index in the years assessment.

The Norwegian Combined Survey Index (Table E5) indicates an increase in the total stock during the last four years. However, there is no clear year class pattern in the data and some ages are consistently underestimated relative to adjacent age groups (e.g. age 9 and partly age 4). The highest indices were observed for age seven, with exception of the three last years when age 1 was most abundant. That indicates that the catchability of younger ages (i.e. those primarily from northern surveys) are not comparable with the older ones (i.e. those primarily from the slope). This is probably a result of pooling different surveys using different gears. These weaknesses reduce the applicability of the combined surveys, and the Working Group advises that further work be done to improve the combined index in the future.

Also in the Russian bottom trawl surveys in October-December (Table E6) it is difficult to identify year classes that appear consistently either strong or weak across ages. In previous Working Group reports this survey series was the one with the clearest and strongest trends in catchability with age in the XSA calibrations. These surveys are important since they usually cover large parts of the total known distribution of the Greenland halibut within $100-900 \mathrm{~m}$ depth. During the 2002 survey, however, no observations were available from the Exclusive Economic Zone of Norway (NEEZ). Greenland halibut abundance for 2002 was adjusted therefore assuming the same distribution by area as in 2001. The results of the 2003 survey indicated a drastic decline in abundance and biomass of Greenland halibut in the eastern Norwegian Sea in comparison with previous years, however, in 2003 the survey again had significant limitations (WD\#19). Observations on the main spawning grounds were conducted three week later than usual because access to NEEZ was obtained too late (only in December). The number of trawl stations was also insufficient due to the same reason. Much of the work in this area was conducted when peak spawning had been completed and spawning concentrations had already begun to disperse. It is considered that these deficiencies in 2003 survey likely resulted in considerable underestimation of abundance and biomass as well as biased age distribution. It was considered therefore imprudent to use the 2003 data from this survey series in the current assessment.

The Spanish bottom trawl survey (Table E7) shows an increase of Greenland halibut abundance and biomass in the Svalbard-Bear Island area in 2003 after three years with a declining trend. The Norwegian Bottom trawl Survey in the Barents Sea in winter (Table E8) shows no clear trend in the total abundance.

Although representing a larger part of the stock, the new combined survey indices were not successful in establishing consistency in the relative size of year classes at age. Future inclusion of northern parts of the Russian zone may improve the index. Also the joint Russian-Norwegian research program on Greenland halibut may eventually contribute by increasing our understanding of the processes involved. The main objectives are to clarify the migration dynamics of the stock, including vertical distribution and relations with Greenland halibut in other areas. The results may improve both biological sampling and the subsequent assessments.

Abundance indices of 0 -group Greenland halibut are shown in Table A14. There has been a significant decrease of this index compared to previous year.

### 8.2.2 Commercial catch-per-unit-effort (Table 8.6 and E9)

The CPUE from the experimental fishery was found to be considerably higher than in the traditional fishery and has exhibited an increasing trend from 1992-1996. After 1996 the Norwegian CPUE series has varied between 1200 and 1650 $\mathrm{kg} / \mathrm{h}$ with the highest value in 2003 (Table E9). The Russian experimental CPUE series shows an increasing trend since 1997, and this series also shows the highest value in 2003.

### 8.2.3 Age readings

In the current assessment of the Greenland halibut stock, the problem of low abundance at age 9 in the Norwegian data from surveys and catches remains unresolved. Analysis of size composition suggested that the problem is more likely to be related to age reading uncertainties rather than to peculiarities in distribution and migration. At present, work is still underway to address this problem for the future including comparative age reading by Russian and Norwegian experts. Some preliminary results were given to the Working Group, but it is still too early to draw any conclusions. When this work is finished the historical time series will be revised and the results will be submitted to the AFWG meeting for review. The program is planned to come to an end in summer 2005.

Based on the arguments in Section 8.2.1 the Working Group also this year considers the survey indices for ages below age 5 not appropriate for inclusion in the tuning data. Consequently, a standard XSA was run for age 5 and above.

### 8.3.1 Catch-at-age (Table 8.7)

The catch-at-age data for 2002 were updated using revised catch figures and revised Norwegian age composition. Catch-at-age data for 2003 were available from both the Norwegian and Russian fisheries. The combined Norwegian and Russian catch-at-age were used to allocate catches from other countries by age groups. Total international catch-atage is given in Table 8.7. Greenland halibut are usually caught in the range of $3-16$ years old, but the catch is mainly dominated by ages $5-10$. Generally, fish older than age 10 comprise a very low proportion of the catches. The Working Group noted that similar low numbers of age 9 were observed in the catches.

### 8.3.2 Weight-at-age (Table 8.8)

For the years 1964-1969 separate weight-at-age data were used for the Norwegian and the Russian catches. Both data sets were mean values for the period and were combined as a weighted average for each year. A constant set of weight-at-age data was used for the total catches in the years 1970-1978. For subsequent years annual estimates were used. The mean weight-at-age in the catch in 2003 (Table 8.8) was calculated as a weighted average of the weight in the catch from Norway and Russia. The weight-at-age in the stock was set equal to the weight-at-age in the catch for all years.

### 8.3.3 Natural mortality

Natural mortality of Greenland halibut was set to 0.15 for all ages and years. This is the same assumption as was used in previous years.

### 8.3.4 Maturity-at-age (Tables 8.9)

Annual ogives were derived to estimate the spawning stock biomass based on females only using Russian survey data for the years 1984-2002, except for the year 1991. An average ogive computed for 1984-1987 was applied to 19641983. The average of 1990 and 1992 was used to represent the maturity ogive for 1991. For 1984-2002 a three-year running average was applied. In previous assessments a similar procedure using the same data set was implemented but was based on sexes combined. The ogive for 2003 was rejected due to the problems with the Russian survey mentioned above (Section 8.2.1) and the data used was the mean value for 2001 and 2002.

### 8.3.5 Tuning data

The XSA was run with the same tuning series as used in last year's assessment :
Fleet 4: Experimental commercial fishery CPUE from 1992-2003 for ages 5-14.
Fleet 7: Russian trawl survey from 1992-2002 for ages 5-14. The 2003 data was not included in this series due to the problems mentioned in section 8.2.1

Fleet 8: Norwegian Combined Survey from 1996-2003 for ages 5-15.

### 8.4 Recruitment indices (Tables A14, E1-E9)

In addition to the indices mentioned in Section 8.3.5, all surveys in Section 8.2.1 may provide information on recruitment. However, because the dynamics of migration and distribution patterns are not well understood for this stock, it is not known which age should be used for a reliable recruitment estimate. As outlined in previous Working Group reports there is no longer evidence for a major recruitment failure in the 1990's. Nevertheless, the relative size of the individual year classes is still poorly estimated, especially at ages below 5 years.

### 8.5.1 VPA and tuning

The Extended Survivors Analysis (XSA) was used to tune the VPA to the fleets as mentioned in Section 8.3.5. The analyses used survivor estimates shrunk towards the mean of the final 2 years and 5 ages and the standard error of the mean to which the estimates were shrunk was set to 0.5 . The catchability was considered to be independent of stock size for all ages and independent of age for ages 10 and older. These are the same settings as used in last years assessment.

Input data and diagnostics of the final XSA run are given in Tables 8.7-8.10 and log catchability residuals for the three fleets used in the tuning are shown in Figure 8.1.

### 8.6 Results of the Assessment

The diagnostics of the assessment indicate that it is generally unbiased, and describes the trend in stock development reasonably well. The survivor estimates for 2004 for most of the important year classes are determined primarily from the tuning fleet data and in most instances each tuning fleet contributes significantly to the determinations with little effect from inclusion of F shrinkage means in the tuning process. Nevertheless, the assessment diagnostics also indicated substantial uncertainties in absolute values of the survivor estimates determined by the analysis shown by instances of very high residuals, large S.E. $(\log q)$ 's and low $R^{2}$,s in the regression statistics for certain fleets and ages.

### 8.6.1 Results of the VPA (Figure 8.2, Tables 8.11-8.15)

The fishing mortality ( F ) matrix indicates that historically Greenland halibut were fully recruited to the fishery at approximately age 6-7. Since 1991 the age of full recruitment appears closer to age 10 (Table 8.11 ). This is likely due to a substantial proportional reduction in trawler effort since 1991 combined with reduced catchability of some year classes in the fishing areas. Trawlers catch more young fish compared to gillnetters and longliners. Nevertheless, F on ages 6-10 continues to represent the average fishing mortality on the major age groups procecuted by the fishery.

Until 1976 the female spawning stock varied between 60,000 and $140,000 \mathrm{t}$, then it was relatively stable at around $40,000 \mathrm{t}$ until the late 1980's after which it declined markedly. It reached an all time low of 14,000 t by 1995-96 but has been increasing since then to an estimate of 27,000 by 2003, the highest estimated since the late 1980's. .

Prior to the reduction in the early 1990's the fishing mortality had increased continuously for more than a decade and peaked in 1991 at 0.66 . After the reduction the fishing mortality has averaged around 0.3 . The high catch in 1999 resulted in an increase in fishing mortality to 0.40 but since then has declined to 0.21 by 2003, the lowest value estimated for the last 20 years.

Recruitment-at-age 5 has been relatively low in recent years compared to the long term average, and since 1990 lower than in all previous years. Nevertheless, the reduction is not especially dramatic and the 1990-2003 average is about $80 \%$ of the average during the 1980 's.

### 8.6.2 Biological reference points

Given the continuing levels of uncertainty in the current assessment no further attempts were made to develop reference points for this stock.

### 8.6.3 Catch options for 2004

Given the uncertainty around the absolute values of population size at age no catch options are provided.

Compared to last years assessment fishing mortality for 2003 remains the same, however some reduction in stock size is indicated.

|  | Total stock (5+) by <br> 1 January 2003 | SSB by <br> 1 January 2003 | F6-10 in 2003 | F6-10 in 2002 |
| :--- | :---: | :---: | :---: | :---: |
| WG 2003 | 87378 | 31556 | $0.21^{*}$ | 0.20 |

### 8.8 Comments to the assessment

The current assessment was conducted using input data and settings similar to previous years, however, the 2003 results from the Russian survey was not used for reasons stated above (section 8.2.1). The assessment is considered uncertain due to age-reading problems yet to be resolved. Despite the continuing uncertainties in the assessment of this stock as noted above, the current analysis indicated similar trends in F and stock size as observed in the 2003 assessment (see Figure 8.3).

## Table 8.10

Lowestoft VPA Version 3.1

$$
7 / 05 / 2004 \quad 11: 49
$$

Extended Survivors Analysis
Arctic Green.halibut (run: XSAAAG47/X47)
CPUE data from file fleet
Catch data for 40 years. 1964 to 2003. Ages 5 to 15.

Tapered time weighting applied
Power $=\quad 3$ over 20 years

Catchability analysis :
Catchability independent of stock size for all ages
Catchability independent of age for ages >= 10

Terminal population estimation :
Survivor estimates shrunk towards the mean $F$ of the final 2 years or the 5 oldest ages.
S.E. of the mean to which the estimates are shrunk $=.500$

Minimum standard error for population
estimates derived from each fleet = . 300
Prior weighting not applied

Tuning converged after 50 iterations

Figure 8.1. Log catchability residuals by age and year for the tuning fleets included in the assessments. For each graph all bubbles are normalized to the same maximum bubble-size. Open bubbles represent positive values; filled bubbles represent negative values.

Figure 8.2. Historical landings, recruitment, fishing mortality and spawning stock biomass.

Figure 8.3. Comparison between last years assessment and this years assessment both with and without the 2003 data point from the Russian survey.

## WD\# Title

1. Ecological conditions in the Barents Sea, 2003-2004
2. Prognosis for the development of the Barents Sea capelin stock
3. Evaluation of the proposed harvest control rule for Northeast Arctic cod
4. Consumption of various prey species by cod in 1984-2003
5. Prost User Guide
6. Predicting growth of Northeast Arctic cod
7. Estimation of cod discards in the Barents Sea and adjacent waters during the Russian bottom trawl fishery in 1983-2002
8. Assessment of population recruitment abundance of northeastern arctic cod and the Barents Sea capelin considering the environment data
9. The inclusion of data on NEA cod cannibalism into assessment a step forward or two steps back?
10. Predicting natural mortality due to cannibalism for Northeast Arctic cod
11. Acoustic abundance of saithe, coastal cod and juvenile herring Finnmark - Møre autumn 2003
12. Abundance of spawning Northeast Arctic cod spring 2004
13. Estimates of Norwegian catch at age of Northeast Arctic cod
14. Extensions and changes of the Fleksibest model from 2003 to 2004
15. Comparison of NEA cod recruitment estimates obtained in AFWG runs and with help of recruitment model
16. Simulation of year-to-year abundance dynamics of euphausids as fish prey in the Barents Sea
17. Results from macroplankton om research in the Barents Sea in Autumn-Winter 2003/04
18. Is it reasonable to apply the new management scheme adopted by the Joint Rusian-Norwegian Fisheries Commission to NEA cod?
19. Results of the Russian survey of Greenland halibut in the Barents Sea in 2003
20. Modelling of feeding, growth rate and recuitment of the northeast arctic cod with allowance for the ecosystem factors
21. The Spanish NE Arctic Cod Fishery in 2003

WORKING DOCUMENTS
ARCTIC FISHERIES WORKING GROUP 2004

# Is the inclusion of NEA cod cannibalism data into assessment a step forward or two steps back? 

by<br>Y. A. Kovalev, V. A. Korzhev<br>e-mail: kovalev@pinro.ru, korgev@pinro.ru,<br>Polar Research Institute of Marine Fisheries and Oceanography (PINRO), 6 Knipovich St., 193763 Murmansk, Russia, e-mail: inter@pinro.ru

#### Abstract

The study concludes that incorporation of the North-East Arctic cod cannibalism data into the VPA model improves the overall quality of its assessment but only when the entire time-series is considered (1985-2002). This is achieved by better consistency between survey abundance indices and VPA estimates for juvenile cod. In addition, variability in model estimates is also reduced according to retrospective analysis. The improvement is most apparent for estimates of recruitment at age 3, which enhances confidence in predicting recruitment. However, when examining XSA diagnostics for the most recent years the improvement in the quality of the assessment is not quite so clear.

## INTRODUCTION

Data on cod cannibalism were incorporated for the first time into the stock assessment by the ICES Arctic Fisheries Working Group (AFWG) in 1995 (Anon, 1996). Prerequisites to this were calculations of predation by cod on juvenile cod carried out by PINRO and IMR (Dolgov A.V., 1995; Bogstad B. and Mehl S., 1997) using a joint cod stomach content data base (Mehl S. and Yaragina N., 1992). These studies show that predation on juvenile cod by older cod can b0e0 $0 q 0 \mathrm{u} 0 \mathrm{i} 0 \mathrm{t} 0 \mathrm{e} 00 \mathrm{~s} 0 \mathrm{i} 0 \mathrm{~g} 0 \mathrm{n} 0 \mathrm{i} 0 f 0 \mathrm{f} 0 \mathrm{c} 0 \mathrm{a} 0 \mathrm{n} 0 \mathrm{t} 00 \mathrm{a} 0 \mathrm{nd}$ that abundance estimates of cod at younger ages can be improved substantially using this information. After having derived initial estimates of abundance with cannibalism taken into account the Group showed that they were better correlated with survey indices for ages 1 and 2 , which resulted in increased coefficients of determination (Anon., 1996).

Nevertheless, incorporating cod cannibalism data into the NEA cod stock assessment has not been without criticism since it is subject to large estimation errors and that consumption estimates derived by PINRO and IMR differ considerably due to different methods applied (Anon., 1999). The calculation methods underwent a number of modifications in 1997 (Bogstad B. and Mehl S., 1997). However, the Arctic Fisheries Working Group concluded that although consistency with survey indices for ages 1 and 2 improved after incorporation of cannibalism data into the model, further confirmation of its usefulness was required since quality control for stock estimates done on a regular basis by the Arctic Fisheries Working Group, indicates that of abundance for ages 1 and 2 are still poorly estimated (Anon., 2003).

Given these concerns, a study was initiated to examine the effects from incorporation of cannibalism data into the VPA on the quality of stock assessment, to analyze the results from simulations including and excluding cannibalism, and to evaluate their impact on predictions of stock dynamics.

## MATERIALS AND METHODS

The following criteria were used for comparing the quality of the NEA cod stock assessment including cannibalism data with the assessment using constant coefficient of natural mortality (M):

- degree of coherence between model abundance dynamics and survey abundance indices;
- comparison of XSA diagnostics;
- stability of key population parameters in the VPA model when new data are added (retrospective analysis);
- quality of recruitment predictions.

Input data for VPA and survey indices were taken from the 2003 AFWG Report (Anon., 2003). Tuning of the model with XSA using data without cannibalism was carried out in the vpa95-program (Darby C.D. and Flatman S., 1994) and all model parameters were taken identical to those contained in the Group Report. Retrospective estimates were derived
by the retroVPA-program. The RCT3-program was used to predict the abundance of cod recruitment at age 3 for the next one to three years. Statistical calculations were done in Excel.

## RESULTS

The effect from incorporating cannibalism on the coherence of VPA abundance estimates and survey indices

VPA abundance estimates cannot be regarded as independent from survey indices as the latter are used for tuning the model. However, VPA estimates become less dependent on surveys with increasing distance from the terminal year (convergence of the model). For NEA cod convergence of the VPA usually occurs within 5-8 years. Therefore, they can be regarded as independent from survey indices and derived only on the basis of catch-at-age data.

## Consistency between VPA estimates and survey indices

As calculations show estimates derived with cannibalism incorporated are much more consistent with abundance indices from the joint Russian-Norwegian winter trawl-acoustic survey of cod and haddock and with combined acoustic indices of abundance from the same survey and Lofoten acoustic survey (Figs. 1-4).

Figure 1 Indices from joint Russian-Norwegian trawl acoustic surveys of cod and haddock and VPA abundance (x 1 000 fish) estimated with $\mathrm{M}=0.2$.
$\mathrm{R}^{2}$ - coefficient of determination.

Figure 2 Indices from joint Russian-Norwegian trawl-acoustic survey of cod and haddock and VPA abundance (x 1000 fish) estimated with cannibalism included.
$\mathrm{R}^{2}$ - coefficient of determination.

Figure 3 Combined acoustic abundance indices from joint Russian-Norwegian trawl-acoustic survey of cod and haddock and Norwegian Lofoten survey and VPA abundance (x 1000 fish) estimated with $\mathrm{M}=0.2$. $R^{2}$ - coefficient of determination.

Figure 4 Combined acoustic abundance indices from joint Russian-Norwegian trawl-acoustic survey of cod and haddock and VPA abundance (x 1000 fish) estimated with cannibalism included.
$R^{2}$ - coefficient of determination.

Coefficients of determination between indices and estimated abundance increase considerably for ages 1-2 for all surveys after incorporation of cannibalism into the stock assessment (Table 1).

Table 1. Coefficients of determination between survey indices and VPA estimates from tuning with XSA including cannibalism and using $\mathrm{M}=$ const $=0.2$ (for 1985-2003).

| Age group <br> in VPA | Survey |  |  |  |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  | Joint winter survey |  |  |  |  |  |  |  |
|  | with can. | without can. | with can. |  | without can. | with can. |  | without can. |
| $\mathbf{1}$ | 0.66 | 0.10 | 0.48 | 0.08 | - | - |  |  |
| $\mathbf{2}$ | 0.72 | 0.15 | 0.38 | 0.26 | 0.75 | 0.11 |  |  |
| $\mathbf{3}$ | 0.56 | 0.48 | 0.83 | 0.68 | 0.59 | 0.70 |  |  |
| $\mathbf{4}$ | 0.84 | 0.80 | 0.72 | 0.67 | 0.76 | 0.79 |  |  |
| $\mathbf{5}$ | 0.83 | 0.83 | 0.56 | 0.55 | 0.64 | 0.65 |  |  |
| $\mathbf{6}$ | 0.89 | 0.90 | 0.63 | 0.60 | 0.39 | 0.39 |  |  |
| $\mathbf{7}$ | 0.91 | 0.91 | 0.83 | 0.82 | 0.18 | 0.17 |  |  |
| $\mathbf{8}$ | 0.92 | 0.92 | 0.88 | 0.87 | 0.17 | 0.17 |  |  |
| $\mathbf{9}$ | 0.66 | 0.66 | 0.94 | 0.94 | 0.38 | 0.38 |  |  |
| $\mathbf{1 0}$ | 0.73 | 0.73 | 0.97 | 0.97 | 0.02 | 0.02 |  |  |

However, as was said before estimates of absolute abundance for these age groups by VPA are not regarded as reliable and therefore not used when management measures for this stock are developed. Nevertheless, fairly good correlation between abundance estimates for younger ages, derived with incorporation of cannibalism data and survey indices represents confirmation in the reliability of estimates of consumption by cod of juvenile cod. Somewhat less was an increase in coefficients of determination for age 3 and even still less for age 4. This increase of $r^{2}$ is specific only for combined acoustic abundance indices and joint winter bottom survey (Table 1, Figs. 1-4). Conversely, correlation between abundance indices for ages 3 and 4 from the Russian bottom fish survey and VPA abundance estimates slightly deteriorates when cannibalism is incorporated in the assessment (Table 1, Figs. 5,6). It should be noted, that this survey, on the whole, is characterized by noisier signal compared to the two other surveys. For ages older than 4, incorporation of cannibalism into the stock assessment has had only insignificant effect on abundance estimates and has not affected the consistency between estimates and survey indices.

Figure 5 Indices (catch per hour haul) from the Russian bottom fish survey and VPA abundance (x 1000 fish) estimated with $\mathrm{M}=0.2$.
$R^{2}$ - coefficient of determination.

Figure 6 Indices (catch per hour haul) from the Russian bottom fish survey and VPA abundance (x 1000 fish) estimated with cannibalism included.
$R^{2}$ - coefficient of determination.

## XSA diagnostics

Based on the analysis of consistency between VPA estimates and survey abundance indices it can be concluded that incorporation of cannibalism data should have a positive effect on the quality of assessment. However, this conclusion becomes less definitive when results from VPA tuning carried out with XSA are reviewed. A comparison of log abundance residuals between the model and surveys indicates that when cannibalism is incorporated values of residuals can both decline and increase (Table 2). A slightly improved correlation between VPA estimates and survey indices after cannibalism data had been included in the analysis was noted only for the joint winter survey, which indicated in a considerable reduction of residuals for most problematic points (years from 1993 to 1995).

Table 2. Difference between absolute values of residuals in XSA tuned with and without cannibalism

Although including cannibalism data in the assessment generally improves the quality of the overall assessment for the full time series it is less clear for the most recent years. The matrix of residuals in VPA tuning was examined further as a way of presenting the degree of correlation between survey indices and VPA estimates, with the only difference being that VPA tuning is carried out for a considerably shorter time-series (1993-2003) and power regressions are used for ages 3-5. In addition, an important difference is the time series weighting used in XSA. Under this option, the further the year under consideration is from the terminal year the less is the weight of data (i.e. reduced impact on the regression function and assessment output).

Calculation of abundance for the terminal year deserves special scrutiny as it has the highest significance in developing management measures for the fishery. Fig. 7 shows results from comparison of various parameters for diagnostics of abundance estimates for the terminal year, in the 2002 and 2003 assessment years. Clearly, incorporation of cannibalism data into VPA increases, as a rule, estimates of initial abundance for each age in proportion to abundance of cod of that age consumed. Correspondingly, estimates of survivors' abundance in the end of the year derived on the basis of regression and survey index in terminal year will be higher in the model, which incorporates cannibalism (two top diagrams in the figure). It will increase proportionately to the increase in consumption by cod of successive age groups.

A comparison of internal log standard errors, which are a measure of the total log standard error for all surveys, shows that in the model without cannibalism they are, as a rule, smaller. External log standard errors show the degree of divergence between estimates of terminal abundance derived from individual surveys. As shown by the two bottom diagrams in Fig. 7 divergence between estimates from different surveys can both increase and decline after incorporating cannibalism data into the model. The effect from inclusion of cannibalism is related to the year of assessment (data series used) and can impact on the magnitude of between estimated errors with and without cannibalism and even on their behaviour. For instance, with respect to the 2002 assessment (Fig. $7 \mathrm{c}, \mathrm{e}$ ) it can be stated,
that inclusion of cannibalism, in a large part, had an adverse effect on the quality of abundance estimates for survivors in the terminal year by having increased the internal log standard error for practically all ages. This led to considerably increased inconsistency in abundance estimate for ages 3 and 4. With respect to the 2003 assessment the conclusion is not that explicit. Internal and external log standard error increased only slightly, and for age 3 the divergence between estimates by different surveys was reduced markedly (Fig. 7 d, f).

## The effect from inclusion of cannibalism on variability of estimates when new data are added into VPA (retrospective analysis)

Retrospective analysis of population parameters such as recruitment at age 3, spawning stock biomass and fishing mortality has shown that VPA estimates for individual years could vary considerably in later assessments (new data added). For the period under consideration, the estimates for years 1993 and 1994 were most unstable (Fig.8). Inclusion of cannibalism into the model reduces both the level of bias and length of the period over which estimates stabilize. This is particularly clear for recruitment estimates. For instance, recruitment estimates by the model without cannibalism derived using data for 1994-1996 differ considerably from estimates derived the longer time series (Fig. 8 a). However, in the model with cannibalism, only the 1994 estimate for recruitment differs from later calculations (Fig. 8 b). This model also reduced bias in SSB and F estimates for 1994. These tendencies are stronger when variations in estimates of recruitment, SSB and F for each individual year are reviewed. In the first three years of assessment CV's for estimates of these parameters are generally smaller for the model with cannibalism (Fig. 9b). And CV's for a larger number (more than 5) of assessments (years in retrospective analysis) by the same model are always smaller (Fig.9a), which is also indicative of their faster stabilization.

## The effect from inclusion of cannibalism into the VPA on the quality of recruitment predictions

A time-series comparison for recruitment at age 3 and abundance of the same year classes at a younger age (survey indices) indicates that inclusion of cannibalism into VPA results in more reliable estimates. Dynamics of abundance at age 3 estimated with cannibalism shows much better consistency with almost all indices (Fig.10).

Figure 10 Coefficients of determination between recruitment at age 3 estimated by VPA and survey indices:
Russian trawl-acoustic survey, catch per hour haul in ICES SA I+IIb

1 - age $0+$;

2 - age 1+;

3 - age 2+;

Joint Russian-Norwegian survey of cod and haddock
4 - age 1, catch per effort;
5 - age 1, acoustic estimate;
6 - age 2 , catch per effort;

7 - age 2, acoustic estimate;
8 - age 3, catch per effort;
9 - age 3, acoustic estimate.
Relationships between indices at age $0-2$ and abundance at age 3 estimated by VPA are used as a basis for predicting recruitment by the AFWG applying RCT3. Including cannibalism data into the assessment produces recruitment predictions of better quality (Fig.11). Excluding cannabalism data from the assessment gives higher predictions of recruitment but with a clear trend in bias (Fig. 11). Before 1998, predictions tended to overestimate the recruitment abundance, but after 1999 to underestimate it. This probably may be explained in that variability of estimates derived without cannibalism is smaller than variability of actual abundance of age 3. Given this, in a situation when survey indices show a considerable increase in abundance for this age group, subsequent calculations by VPA, which uses
catch data only, do not show an icreases to the same extent. Similarly, VPA estimates "do not catch up" with actual rapid decline of recruitment abundance. Therefore, an effect of "smoothing" the real dynamics of abundance for younger age groups in the model without cannibalism takes place (Fig. 11 a and b, VPA).

Figure 11 Consistency between VPA estimates of recruitment and predictions for 1, 2 and 3 years ahead done in RCT3program on the basis of VPA calculations without (a) and with (b) cannibalism.

## 1 Introduction

This document contains an evaluation of the harvest control rule for Northeast Arctic cod suggested by the Joint Norwegian-Russian Fisheries Commission in November 2002. The Commission also asked for a similar evaluation for Northeast Arctic haddock, but this evaluation will be delayed until the evaluation for cod has been completed.

## 2. Background

### 2.1 Decisions made at the $31{ }^{\text {st }}$ Session of The Joint Norwegian-Russian Fishery Commission in November 2002

At the $31^{\text {st }}$ Session of The Joint Norwegian-Russian Fishery Commission (hereafter referred to as the Commission) in November 2002 the following decision was made:
"The Parties agreed that the management strategies for cod and haddock should take into account the following:

- conditions for high long-term yield from the stocks
- achievement of year-to-year stability in TACs
- full utilisation of all available information on stock development

On this basis, the Parties determined the following decision rules for setting the annual fishing quota (TAC) for Northeast Arctic cod (NEA cod) from 2004 and onwards:

- estimate the average TAC level for the coming 3 years based on $F_{p a}$. TAC for the next year will be set to this level as a starting value for the 3 year period.
- the year after, the TAC calculation for the next 3 years is repeated basing on the updated information about the stock development, however the TAC should not be changed by more than $+/-10 \%$ compared with the previous year's TAC.
- if the spawning stock falls below $B_{p a}$, the Parties should consider a lower TAC than the decision rules would imply.

The Parties agreed on similar decision rules for haddock, based on $F_{p a}$ and $B_{p a}$ for haddock, and with a fluctuation in TAC from year to year of no more than +/-25\% (due to larger stock fluctuations).

The Parties agreed that the working group, which worked out the "Basic Document regarding the main principles and criteria for long term, sustainable management of living marine resources in the Barents and Norwegian Seas" during the following year should illustrate how these decision rules will work. The working group shall, in particular, evaluate what level of percentage change in TAC from year to year will be reasonable to utilise. ${ }^{l /}$

[^23]Following this request, the 'Basic Document group' prepared a report to Norwegian and Russian authorities (Anon., 2003).

### 2.2 Request to ICES

The Norwegian Ministry of Fisheries sent a letter to ICES (February 2003), requesting that the advice for TAC on cod and haddock should correspond to the decision rule given in Section 2.1.

Although the letter contained a request that ICES should give advice according to the decision rules established by the Commission, ICES was not asked to evaluate if the decision rules are in accordance with the precautionary approach (PA). However, for any catch option, ICES will routinely state whether it is compatible with the PA, depending on the resulting fishing mortality.

### 2.3 Evaluation of biological reference points by SGBRP

To evaluate whether the existing biological reference points for Northeast Arctic cod should be modified, a Study Group on Biological Reference Points for Northeast Arctic cod (SGBRP) established by ICES met in Svanhovd, Norway in January 2003 (ICES, 2003b). Based on the approach outlined in by the Study Group on the Further Development of the Precautionary Approach to Fishery Management (SGPA) at its December 2002 meeting (ICES 2003a), the SGBRP proposed the following new reference points for Northeast Arctic cod: $B_{l i m}=220000 t, B_{p a}=460000$ $\mathrm{t}, \mathrm{F}_{\text {lim }}=0.74$ and $\mathrm{F}_{\mathrm{pa}}=0.40$. ACFM accepted the proposed revisions in June, 2003.

### 2.4 Evaluation of the proposed harvesting strategy by ICES' Arctic Fisheries Working Group in 2003

The Arctic Fisheries Working Group met in San Sebastian, Spain, 23 April-2 May 2003 (ICES, 2003d). Concerning the proposed harvesting strategy for cod, the Group stated that (Section 3.8.4 in the report).
"The appropriateness of the maximum percentage change will be evaluated by a dedicated working group appointed by the Joint Norwegian Russian Fishery Commission before a final decision is made. However, the AFWG notice that the stock fluctuations from year to year may exceed $+/-10 \%$. An attempt to retain catch variations within the $10 \%$ may entail both underfishing and overfishing of the stock. It is necessary to test the decision rule with simulation models in order to consider various scenarios of SSB dynamics (both for an increasing and decreasing stock situation). This work needs to be done before the rule is adopted.

A "multi-annual" rule as described above for setting the TAC for Northeast Arctic cod has not previously been considered by ICES Working and Study Groups. Some general points relating to such rules were noted:

According to the ACFM form of Advise any target $F$ should be below $F_{p a}$ to be in accordance with the Precautionary Approach. The medium-term prognosis shows that the new strategy will not always keep $F$ below $F_{p a}$. The reason is that when $F=F_{p a}$ is applied for a three-year period, the stock will in many cases increase, so that the catch corresponding to $F=F_{p a}$ will also increase during the period. When applying the 3-year averaging method to find the TAC in the first year, this will thus be higher than the TAC corresponding to $F=F_{p a}$ in the first year.

Involving the medium-term prognosis (three years into future) in the setting of quotas for the next year also introduces additional uncertainty due to uncertainty in the prognosis of growth, maturation, recruitment and mortality. Thus, the fishing mortality associated with a multi-annual TAC may have to be set lower than $F_{p a}$ in order to ensure the same probability of avoiding limit values. The ICES should provide guidelines on how to evaluate the effect on multi-annual TAC rules on reference points.

The Working Group did not have available software which could perform a risk analysis applying the agreed harvest control rule."

### 2.5 Advice given by The Advisory Committee on Fisheries Management (ACFM) in 2003

The ACFM report on NEA cod as of May 2003 and its answer to the request for advice made by the Commission (Section 3.1.10) is given in ICES (2003c). ACFM gave the advice that the TAC on NEA Cod should not exceed 398 000 tonnes, corresponding to a fishing mortality of $\mathrm{F}_{\mathrm{pa}}=0.40$. ACFM also calculated the catch corresponding to the decision rule, as requested, and did not find this catch in accordance with the PA, because it would lead to a fishing mortality above $\mathrm{F}_{\mathrm{pa}}$ for 2004. ACFM did not evaluate whether the decision rule as such would be in accordance with the PA, but made the following statement:
"The 2004 catches calculated by applying the harvest rule imply a fishing mortality above $F_{p a}$. However, the precautionary reference points as currently used by ICES are defined in the context of advising on an annual TAC based on a predicted catch based on a maximum F. The objective of this Harvest Control Law is to have a low risk of falling below a $B_{\text {lim }}$ point. The proposed harvest control rule or modifications of it may actually secure a low probability of SSB dropping below a $B_{\text {lim }}$ point and hence be in accordance with the Precautionary Approach because the decision rule is different from that implied in calculating $F_{p a}$. Simulation studies are needed to reveal if this is the case. ICES is prepared to review and evaluate results of such studies."

To summarize, ACFM states that the decision rules may be in accordance with the precautionary approach, but conclusions cannot be drawn at the moment. As a consequence, advice for 2004 was given on the basis of the existing "Form of ICES advice", that is, on an annual assessment of $\mathrm{F}_{\mathrm{pa}}$.

### 2.6 Commission meeting 2003

The $32^{\text {nd }}$ meeting of the Commission in November 2003 asked for studies of the maximum long-term yield for cod. Such studies can also be carried out using the model described in this document.

## 3. Method for evaluating harvest control rules

### 3.1 Theoretical background

The approach used for evaluating the proposed management plan is the same as outlined in Skagen et al. (2003). The proposed management plan, as well as alternative plans, will be tested by doing long-term stochastic simulations. This approach is in line with that outlined by ICES (2003e). We also take into account the work done by the Study group for Long-Term Advice (ICES, 2004).

### 3.2 Description of the software used

Software, which could evaluate the ' 3 -year' rule in a stochastic setting, was not available. Thus, it was decided at IMR to develop new software for such projections. This new program (Åsnes, 2004) is named 'PROjections Stochastic' or PROST. It is written in Java.

## 4. Population model for Northeast Arctic cod

It is important to remember that the results of an evaluation of a harvest control rule are dependent on the population model used. Previous analyses concerning reference points and harvest control rules (e.g. ICES, 2003b) have used a rather simplistic population biology, with no modelling of density-dependent effects and recruitment only being dependent on SSB. However, we found it appropriate to try to include as much biological knowledge as possible in our population model, as advocated e.g. by Ulltang (1996). Our results will be compared with results using a simpler population model.

The results may be altered e.g. by introducing TEP instead of SSB in the model, modelling cannibalism explicitly or by introducing length structure in the model. Multispecies models may also give different results from single-species models.

The following units are used in this paper:

Individual weight: kg
Recruitment: billion $\left(10^{9}\right)$ individuals
Stock biomass: million tonnes

### 4.1 Recruitment

### 4.1.1 The segmented regression approach

ICES (2003b) modelled the stock/recruitment relationship for NEA cod using the segmented regression approach. In that analysis, recruitment at age 5 was used due to problems with including discards and cannibalism of age 3 and 4 in the time series. The report states that age 5 should be used until more accurate estimates of the number at age 3 are available. For our simulation studies, however, we want to use recruitment at age 3.

The choice of time series is crucial here. If we use the entire time series it will be logical not to include natural mortality from cannibalism in the model at all when the stock-recruitment function is based on data without cannibalism. If we hypothetically had a full time series including cannibalism we would expect this to show higher recruitments at high stock and rather unchanged at low stock, thus giving another stock-recruitment function. In that case our model for estimating stock size and yield should take account of the increased cannibalism at high stock. When our stockrecruitment function does not include cannibalism, our population model should not either. Our main analysis will thus be without cannibalism. We will include some additional analysis to illustrate some effects of cannibalism.

A segmented regression between spawning stock and recruitment at age 3 (no cannibalism) for the year classes 19461999 is shown in Fig. 1. The segmented regression was performed in the same way as described in ICES (2003b), using the method described by O'Brien and Maxwell (2002).

Figure 1. Segmented regression between spawning stock biomass and recruitment at age 3 (no cannibalism).
The segmented regression shown in Figure 1 can be written as
$f(S S B)=\min \left(\frac{\alpha}{\beta} S S B, \alpha\right)$
where $\alpha=0.529$ and $\beta=0.224$.

### 4.1.2 Extending the segmented regression approach by including a cyclic term and the mean weight in the spawning stock

Fig. 2 shows the residuals obtained when fitting the segmented regression. These residuals vary in a cyclic way with time, but there is also a significant ( $\mathrm{p}<0.05$ ) declining trend over time. This trend may be due to the change in size and sex composition of the spawning stock. Marshall et al. (2003) found that the correlation between total egg production (TEP) and recruitment is stronger than the correlation between spawning stock biomass and recruitment. The TEP/SSB
ratio is affected both by the size composition and the sex ratio in the spawning stock. The relative fecundity ( $\mathrm{g} \mathrm{eggs} / \mathrm{kg}$ spawner) increases with increasing size (length/weight) of spawners (ICES 2003f), and the mean weight of spawners has declined. Fig. 3 shows the mean weight $\bar{w}$ in the spawning stock, which has a significant ( $\mathrm{p}<0.01$ ) declining time trend. Also, stocks having a higher proportion of large cod have higher proportions of females simply because of the earlier maturation and mortality of females (Ajiad et al. 1999; Jakobsen and Ajiad 1999). Fig 4.9 in ICES (2004) shows that the female SSB/total SSB ratio for Northeast Arctic cod covaries systematically with the mean length of the spawning stock.

Thus, we chose to include $\bar{w}$ in the stock/recruitment relationship in order to take into account the change in the ratio between TEP and SSB over time. A more satisfactory approach would be to use a length-and sex-structured population model where fecundity can be calculated for each length class of female fish based on the equations given in ICES (2003f). Such a population model is under development (Bogstad et al., 2004), but could not be used in the present study. The TEP/recruitment relationship given in Marshall et al. (2003) could be compared with a relationship where SSB and $\bar{w}$ is included to check how much of the recruitment variation is explained by TEP vs. that explained by SSB and $\bar{w}$.

Figure 2. Time variation of residuals for segmented regression recruitment

Figure 3. Mean weight ( kg ) in cod spawning stock

A reasonable description of the stock/recruitment relationship may thus be

$$
\begin{equation*}
R_{3}(\text { year }+3)=f(\operatorname{SSB}(\text { year })) e^{\text {AoSin }\left(\frac{2 \pi(\text { year }-1946+\varphi)}{T}\right)+k\left(\bar{w}(\text { year })-w_{0}\right)+\varepsilon} \tag{2}
\end{equation*}
$$

where $\varepsilon$ is a stochastic term and $\mathrm{f}(\mathrm{SSB})$ is given by equation (1). $R_{3}$ (year +3 ) is the number of age 3 fish in the beginning of year $y+3$.

We first tried to include the cyclic term in the exponent, and then both this term and the $\bar{w}$ term. The results of the model fit (minimising log SSQ), which was carried out using Solver in Excel, are given in Table 1. The residuals when both terms are included are shown in Fig. 4, and the predicted vs. observed values of recruitment using equation (2) with $\varepsilon=0$ are shown in Fig. 5. The model does not pick up the outstanding year classes, but still performs fairly well. The time trend is no longer significant ( $\mathrm{p}>0.05$ ).

| Model | $\alpha$ | $\beta$ | A | $\varphi$ | T | k | $\mathrm{w}_{0}$ | $\varepsilon$ | Log <br> (SSQ) | proportion of <br> variability <br> explained <br> compared to <br> constant <br> recruitment |
| :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- |
| Constant <br> recruitment |  |  |  |  |  |  |  |  | 26.90 |  |
| Only segmented <br> regression | 0.529 | 0.224 |  |  |  |  |  |  | 19.76 | 0.27 |
| Cyclic term <br> included | 0.529 | 0.224 | 0.43 | -1.92 | 6.57 |  |  |  | 14.55 | 0.46 |
| Cyclic and mean <br> weight term <br> included | 0.529 | 0.224 | 0.53 | -2.02 | 6.55 | 0.19 | 4.29 |  | 12.68 | 0.53 |
| Cyclic, mean <br> weight and <br> stochastic terms <br> included | 0.581 | 0.286 | 0.52 | -2.04 | 6.53 | 0.19 | 4.30 | 0.497 | 13.11 | 0.51 |

Table 1. Results of fit of recruitment model

It is important to include the cyclic variation in our recruitment model because the harvest control rule has to be capable of dealing with a series of weak year classes in a precautionary way. Several authors (e.g. Ottersen and Stenseth, 2001) have found a good correlation between temperature and recruitment, and there are cyclic variations in temperature. However, reliable long-term (or even medium-term) predictions of temperature variation are not available (Ottersen et al., 2000), and thus we do not include temperature in our recruitment model.

Figure 4. Residuals when cyclic and mean weight terms are included in the recruitment function.

Figure 5. Observed vs. modelled recruitment when cyclic and mean weight terms are included in the recruitment function.

Figures 6 and 7 show the residuals vs. SSB and vs. $\bar{w}$, using the model with a cyclic term as well as a mean weight term. The residuals are not significantly correlated ( $\mathrm{p}>0.05$ ) with SSB or $\bar{w}$.

Figure 6. Dependence of SSB on residuals

Figure 7. Dependence of $\bar{w}$ on residuals.

### 4.1.3 Determining the variance in the stock-recruitment function

We then need to determine the stochastic term $\varepsilon$ in (2). We will follow the approach outlined by Skagen and Aglen (2002). They suggested 3 quality criteria for stochastic stock-recruitment functions:

1. Independence between residuals and SSB
2. Probability coverage
3. The recruitment estimates should be unbiased.

Criterion 1) has been tested for by looking at the deterministic stock-recruitment function (Fig. 6). The residuals are not correlated with SSB, but the variability in recruitment seems to be higher at low SSBs, and this could be modelled by making the variance a function of SSB.
2) is a control that the distribution assumed for the residuals is adequate, while 3 ) may be used as an additional constraint when finding the parameters of the stock-recruitment function.

Assuming that each of the historic residuals is equally likely, the rank of each of them, divided by the number of observed residuals, gives the empirical cumulated probability of the historical residuals. On the other hand, according to the model that is assumed for the residuals in the prediction, there corresponds a cumulated probability for the value of each observed residual. Each of these model probabilities should be close to the empirical cumulated probability of the same historic residual. The Kolmogorov goodness of fit test is based on this reasoning, and the Kolmogorov test statistic can be derived directly from the pairs of modelled and observed values.

The fit was done using Solver in Excel spreadsheets described by Skagen and Aglen (2002). Constraints on zero correlation between residuals and SSB and on the sum of the difference between modelled and observed recruitments being zero were applied. In the fitting procedure, all the parameters in the stock-recruitment function were re-estimated (Table 1). The parameters $\alpha$ and $\beta$ in the segmented regression (equation (1)) changed somewhat, but the other parameters were very close to the values estimated using the corresponding deterministic model. Assuming a lognormal distribution, i.e. $\varepsilon=N(0, \sigma), \sigma=0.497$ gave the best fit to the data. Fig. 8 and 9 show the probability coverage and observed vs. modelled recruitment for this distribution. The fit seems to be rather satisfactory.

The final test in any case is to take the distribution (or at least the standard percentiles) of recruitments from a long-term prediction and compare with the historic recruitments generated by similar levels of SSB.

Figure 8. Probability coverage for stochastic stock-recruitment function

Figure 9. Observed vs. modelled recruitment for stochastic stock-recruitment function.

### 4.2 Growth(weight at age)/Maturity

There are several possibilities for modelling this:

1) Using a time series average
2) To draw randomly weight at age in stock and catch and maturity at age from the entire time series (i.e. draw a year)
3) To fit a model for stock size dependence of growth and maturity to the entire time series and to simulate the uncertainty using a statistical model (e.g. normal distributed residuals with estimated $\sigma$ ) or draw randomly observed residuals around fitted trends. For weight at age, the model could probably be linearly dependent of total stock biomass (TSB), while for the maturity at age, it could be assumed to be a sigmoid function of TSB.

Approach 1 does not take the uncertainty in those parameters in account. Approach 2 will overestimate the uncertainty related to changes in those parameters. We have not observed so wide range of changes in weight and maturity as we will simulate by this approach. Actually there are trends in these data and considerably less variation around trends. This approach will also give a bias in the results. When F is low, we will overestimate TSB, SSB and yield, when F is high we will underestimate those quantities. In order to avoid that, we will try approach 3). For all approaches, it could be discussed whether the entire time series should be used.

Heino et al. (2002) found that both increase in growth rate and change in age-and sex-specific tendency to mature have contributed to the observed trend towards earlier maturation. Thus, part of the change may represent a fisheries-induced adaptive genetic change. We will not take this into account in our analysis.

### 4.2.1 Growth (weight at age)

We have used the entire time series (stock weights in 1947-2003 vs. total stock biomass in 1946-2002) to fit a densitydependent model for weight at age $(\mathrm{kg})$ in the stock $w s_{a, y}$ for ages 3-9. The model is of the form
$w s_{a, y}=-\alpha_{a} T S B_{y-1}+\beta_{a}(3)$,
where $\mathrm{TSB}_{\mathrm{y}}$ is the total stock biomass in year $y, a$ is age and $\alpha_{\mathrm{a}}$ and $\beta_{\mathrm{a}}$ are constants. The regressions are shown in Figure $10 \mathrm{a}-\mathrm{g}$, and the parameters in the regressions are given in Table 2.

| Age | $\alpha_{\mathrm{a}}$ | $\beta_{\mathrm{a}}$ | $\mathrm{R}^{2}$ | p |
| :--- | :--- | :--- | :--- | :--- |
| 3 | 0.010745 | 0.3206 | 0.0138 | $>0.05$ |
| 4 | -0.030914 | 0.7607 | 0.0249 | $>0.05$ |
| 5 | 0.058946 | 1.3779 | 0.0524 | $>0.05$ |
| 6 | -0.11788 | 2.2852 | 0.1202 | $<0.01$ |
| 7 | -0.21385 | 3.5271 | 0.2076 | $<0.01$ |
| 8 | -0.37067 | 5.1876 | 0.2771 | $<0.01$ |
| 9 | -0.70013 | 7.4611 | 0.4273 | $<0.01$ |

Table 2. Parameters in regression for density-dependent weight at age in the stock.
We see that the relationship for ages $3-5$ is insignificant. For those ages TSB could not be used as predictor. The biology and food composition of those age groups is different from that of older ages. We may use average values and model residuals or we may try to find relationship between weights at age and abundance at age for these age groups. For age $10+$ we will use a historic average.

Figure 10a. Weight in stock vs. total stock biomass for age 3 cod.

Figure 10b. Weight in stock vs. total stock biomass for age 4 cod.

Figure 10c. Weight in stock vs. total stock biomass for age 5 cod.

Figure 10d. Weight in stock vs. total stock biomass for age 6 cod.

Figure 10e. Weight in stock vs. total stock biomass for age 7 cod.

Figure 10f. Weight in stock vs. total stock biomass for age 8 cod.

Figure 10 g . Weight in stock vs. total stock biomass for age 9 cod.
Weight at age in catch is modelled as a function of weight at age in stock, using equation (4):

$$
\begin{equation*}
w c_{a, y}=\alpha_{a} w s_{a, y}+\beta_{a} \tag{4}
\end{equation*}
$$

The values of $\alpha_{\mathrm{a}}$ and $\beta_{\mathrm{a}}$ for ages 3-9 are given in Table 3. The regressions are based on data from 1983-2002, when observations of stock weights at age from surveys are available.

| Age | $\alpha_{\mathrm{a}}$ | $\beta_{\mathrm{a}}$ | $\mathrm{R}^{2}$ | p |
| :--- | :--- | :--- | :--- | :--- |
| 3 | 1.6652 | 0.2978 | 0.5847 | $<0.01$ |
| 4 | 0.9358 | 0.5561 | 0.8108 | $<0.01$ |
| 5 | 0.9738 | 0.4948 | 0.8935 | $<0.01$ |
| 6 | 0.9008 | 0.5807 | 0.9077 | $<0.01$ |
| 7 | 0.7962 | 0.9652 | 0.6450 | $<0.01$ |
| 8 | 0.6539 | 1.9342 | 0.5599 | $<0.01$ |
| 9 | 0.1927 | 5.4996 | 0.0447 | $>0.05$ |

Table 3. Parameters in regression for weight at age in the catch vs. weight at age in the stock.

Weight at age in the catch will be calculated directly from weight at age in the stock using equation (4). Uncertainties associated with the regression will not be taken into account, as the uncertainty in weight at age in the stock already is modelled. For ages 9 and older weight at age in the catch is set equal to weight at age in the stock.

### 4.2.2 Maturity at age

We suggest the following model for density-dependent maturation:
$p_{a, y}=\frac{1}{1+e^{-\alpha_{a}\left(T S B_{50, a}-T S B_{y-1}\right)}}$ (5)
where $\mathrm{p}_{\mathrm{a}, \mathrm{y}}$ is the proportion of mature cod at age $a$ in year $y$. We first fitted values for $\alpha_{\mathrm{a}}$ and $\mathrm{TSB}_{50, \mathrm{a}}$ separately for each age group (3-13). This gave a total sum of squares $\left(\sum_{a, y}\left(p_{a, y}^{\bmod }-p_{a, y}^{o b s}\right)^{2}\right)$ of 7.95. It was then seen that the number of parameters could be reduced significantly by assuming that $\alpha_{a}$ is the same for all age groups and that
$T S B_{50, a}=\gamma a-\kappa(6)$

This gave a marginally higher total sum of squares: 8.16. Also, the proportion mature at age 4 became unrealistically high (higher than age 5 values) at low stock sizes when fitting age-specific values of $\alpha_{\mathrm{a}}$ and $\mathrm{TSB}_{50, \mathrm{a}}$. This is avoided when using equation (6) to describe the age-dependence of TSB and assuming that $\alpha_{a}$ is the same for all age groups. This gives the following equation for the proportion mature at age:
$p_{a, y}=\frac{1}{1+e^{-\alpha\left(\gamma a-\kappa-T S S_{y-1}\right)}}$ (7)
with parameter values $\alpha=1.08, \kappa=5.54, \gamma=0.91$.
The model fit for ages 4-10 is shown in Figures 11a-g.

### 4.3 Cannibalism mortality

As mentioned in Section 4.1.1, cannibalism will not be included in our main analysis because our stock-recruitment function does not include cannibalism. However, it is important to have models for cannibalism mortality available so that the effect of cannibalism on the population dynamics can be explored. Natural mortality due to cannibalism (M2) has been calculated for the period 1984-present, when annual stomach content data are available. This mortality can be significant for age 3 and 4 cod (ICES 2003d), and should thus be modelled. Kovalev (2004) found that cannibalism mortality for age 3 and 4 in year $y$ showed good correlation both with $S S B_{y-3}$ (Fig. 12a and b) and with the biomass of age 6 and 7 cod in the beginning of year $y$ (Fig. 13a and b). The two models can be described by the following formulas:
$M 2_{y, a}=\alpha_{a} S S B_{y-3}+\beta_{a}(8)$
or
$M 2_{y, a}=\alpha_{a}\left(N_{y, 6} W_{y, 6}+N_{y, 7} W_{y, 7}\right)+\beta_{a}(9)$
where the parameter values are given in Table 4 for equation (8) and in Table 5 for equation (9). Observed residuals around trends could be used to model uncertainty.

At a later stage, the population model should be extended down to age 1 and cannibalism on age 1 and 2 cod could then be modelled explicitly instead of including it in the stock-recruitment relationship. Such work is in progress (Bogstad et al., 2004).

Figure 12a. M2 for age 3 vs. SSB in year-3

Figure 12b. M2 for age 4 vs. SSB in year- 3

| Age | $\alpha_{\mathrm{a}}$ | $\beta_{\mathrm{a}}$ | $\mathrm{R}^{2}$ | p |
| :--- | :--- | :--- | :--- | :--- |
| 3 | 0.6419 | 0.0738 | 0.75 | $<0.01$ |
| 4 | 0.2694 | 0.1362 | 0.72 | $<0.01$ |

Table 4. Parameters in regression for cannibalism mortality as a function of spawning stock biomass 3 years earlier.

Figure 13b. M2 for age 4 vs. biomass of age 6 and 7 cod.

| Age | $\alpha_{\mathrm{a}}$ | $\beta_{\mathrm{a}}$ | $\mathrm{R}^{2}$ | p |
| :--- | :--- | :--- | :--- | :--- |
| 3 | 0.5004 | -0.1026 | 0.41 | $<0.01$ |
| 4 | 0.2470 | -0.0707 | 0.55 | $<0.01$ |

Table 5. Parameters in regression for cannibalism mortality as a function of the biomass of age 6 and 7 cod in the beginning of the year.

### 4.4 Fishing pattern

The fishing pattern could be drawn randomly from some period. There is, however, no reason to include periods when the pattern was significantly different from what it can be expected to be in the future, due to different regulations. It should also be taken into account that the fishing pattern is dependent on the size at age. Since the fishing patterns are calculated by a VPA, the computed Fs contain all the noise in the catch data. It may be necessary to smooth the fishing pattern in order not to include more noise than appropriate.

## 5. Modeling of assessment error

Special attention is needed to model the assessment uncertainty (random error/bias) properly. The way this is done at present, without reproducing future assessments, it becomes more of a test on robustness of the rule to errors in the assessment. We suggest to leave it at that, and use the experience from the Svanhovd meeting (ICES, 2003b) as a guideline as to how much error the decision rule should be able to cope with. If we follow the logics used for our PA reference points we could argue that the decision rule should ensure against collapse even in case of one year with extreme assessment error. (The most extreme experienced is about a factor of 2 both for F and SSB). The standard error could thus be set such that the $95 \%$ percentile of the distribution gives an error of a factor 2 .

## 6. Choice of harvest control rules to be explored

We will explore harvest control rules both with usual F-based strategies as well as F-based strategies of the '3-year average' type (see Section 2.1 and 2.4). The fishing mortality may in both cases depend on SSB in the following way:
$\mathrm{F}=\mathrm{F}_{1}=$ constant when $\mathrm{SSB}>\mathrm{B}_{1}\left(\mathrm{~B}_{1}\right.$ should be set $\left.>\mathrm{B}_{\text {lim }}\right)$.
For $\mathrm{SSB}<\mathrm{B}_{1}$ we will explore two rules:

- $\mathrm{F}=\mathrm{F}_{1}$
- reduce F linearly from $\mathrm{F}_{1}$ at $\mathrm{SSB}=\mathrm{B}_{1}$ toward 0 at $\mathrm{SSB}=0$ (or some other SSB level e.g. $\mathrm{B}_{\mathrm{lim}}$ ).

Let the dependence of F on SSB be given as $g(S S B)$. When using the ' 3 -year average rule', we first compute $F_{y}$ ${ }_{=} g(S S B(y))$, where $y$ is the year for which we want to determine the quota. We then use the ' 3 -year average rule' with $F=F_{y}$ to calculate the quota in year $y$. This is done in order to ensure that F never increases when SSB decreases. If one use the ' 3 -year average rule' above $\mathrm{SSB}=\mathrm{B}_{1}$ but switch to a purely F -based strategy when $\mathrm{SSB}<\mathrm{B}_{1}$, one could in some cases find that SSB values slightly below $B_{1}$ would give a higher $F$ than $\operatorname{SSB}$ values above $B_{1}$.

When $\mathrm{SSB}<\mathrm{B}_{1}$, the limit on percentage change in quota from year to year is not applied.
We should have in mind that both $\mathrm{F}_{\mathrm{pa}}$ and $\mathrm{B}_{\mathrm{pa}}$ are defined in a somewhat different context. These pa-values may be good guesses for $F_{1}$ and $B_{1}$, but other values should be explored, to find optimal values. The really important thing here is that the 'real' model spawning stock biomass remains above $\mathrm{B}_{\text {lim }}$ with high probability.

# Standard Procedure for Assessment XSA/ICA Type 

Stock specific documentation of standard assessment procedures used by ICES.

Stock: $\quad$ Norwegian Coastal cod ....<br>Working Group: Arctic Fisheries Working Group<br>Date: 12-05-04...

## A General

## A.1. Stock definition

Cod in the Barents Sea, the Norwegian Sea and in the coastal areas living under variable environmental conditions form groups with some peculiarities in geographical distribution, migration pattern, growth, maturation rates, genetics features, etc. The degree of intermingle of different groups is uncertain (Borisov, Ponomarenko and Yaragina, 1999). However, taking into account some biological characteristics of cod in the coastal zone and the specifics of the coastal fishery, the Working Group considered it acceptable to assess the Norwegian coastal cod stock (in the frame of ICES) separately from North-East Arctic cod.

Both types of cod (the Norwegian Coastal cod and the North-East Arctic cod) can be met together on spawning grounds during spawning period as well as in catches all the year round both inshore and offshore in variable proportions.

The Norwegian Coastal cod (NCC) is distributed in the fjords and along the coast of Norway from the Kola peninsula in northeast and south to Møre at $62^{\circ} \mathrm{N}$. Spawning areas are located in fjords as well as offshore along the coast. Spawning season extents from March to late June. The 0 and 1-group of NCC inhabit shallow water both in fjords and in coastal areas and are hardly found in deeper trawling areas until reaching about 25 cm . Afterwards they gradually move towards deeper water. NCC starts on average to mature at age 4-6 and migrates towards spawning grounds in early winter. The majority of the biomass (about $75 \%$ ) is located in the northern part of the area (North of $67^{\circ} \mathrm{N}$ ).

Tagging experiments of cod inhabiting fjords indicate only short migrations (Jakobsen 1987, Nøstvik and Pedersen 1999, Skreslet, et al. 1999). From these experiments very few tagged cod migrated into the Barents Sea ( $<1 \%$ ). Investigations based on genetics find large difference between NCC and North-East Arctic cod (NEAC) (Fevolden and Pogson 1995, Fevolden and Pogson 1997, Jørstad and Nævdal 1989, Møller 1969), while others do not find any difference (Árnason and Pálsson 1996, Mork, et al. 1984, Artemjeva and Novikov, 1990). Investigations also indicate that NCC probably consists of several separate populations.

Ongoing investigations on the genetic structure of cod along the Norwegian coast, the Murman coast and in the White Sea will hopefully further elucidate the stock structure of cod in these areas.

## A.2. Fishery

The fishery is conducted both with trawlers and with smaller coastal vessels using traditional fishing gears like gillnet, longline, hand line and danish seine. In addition to quotas, the fishery is regulated by the same minimum catch size, minimum mesh size on the fishing gears as for the North-East Arctic cod, maximum by-catch of undersized fish, closure of areas having high densities of juveniles and by seasonal and area restrictions. The fishery is dominated by gillnet ( $50 \%$ ), while longline/hand line account for about $20 \%$, Danish seine $20 \%$ and Trawl $10 \%$ of the total catch. There was a shift around 1995 in the portion caught by the different gears. After 1995 the portion taken by longline and hand line has decreased, while the portion taken by danish seine has increased. Norwegian vessels take all the reported catch. However, trawlers from other countries probably take a small amount of NCC when fishing near the Norwegian coast fishing for North-East Arctic cod and North-East Arctic haddock.

## A.3. Ecosystem aspects

Not investigated

## B. Data

## B. 1 Commercial catch

From 1996, cod caught inside the 12 n.mile zone have been separated into Norwegian coastal cod and Noertheast Arctic cod based on biological sampling (Berg, et al. 1998) The method is based on otolith-typing. This is the same method as is used in separating the two stocks in the surveys targeting NEAC. The catches of Norwegian coastal cod (NCC) have been calculated back to 1984 . During this period the catches have been between 25,000 and 75,000 t .

The separation of the Norwegian catches into NEAC and NCC is based on:

- No catches outside the 12 n.mile zone have been allocated to the NCC catches.
- The catches inside 12 n.mile zone are separated into quarter, fishing gear and Norwegian statistical areas.
- From the otolith structure, catches inside the 12 n.mile zone have been allocated to NCC and NEAC. The Institute of Marine Research in Bergen has been taking samples of commercial catches along the coast for a long period.

Norwegian commercial catch in tonnes by quarter, area and gear are derived from the sales notes statistics of The Directorate of Fisheries. Data from 8 sub areas are aggregated on 6 main areas for the gears gillnet, long line, hand line, Danish seine and trawl. No discards are reported or accounted for, but there are reports of discards and incorrect landings with respect to fish species and amount of catch. The scientific sampling strategy from the commercial fishing is to have age-length samples from all major gears in each area and quarter.

There are at present no defined criteria on how to allocate samples of catch numbers, mean length and mean weight at age to unsampled catches. The following general process has been applied: First look for samples from a neighbouring area if the fishery extends to this area in the same quarter. If there are no samples available in neighbouring areas, search for samples from other gears with the most similar selectivity in the same area or in neighbouring areas. The last option is to search in neighbouring quarters, first from the same gear in the same area, and than from neighbouring areas and similar gears. Age-length keys from research surveys with shrimp trawl (Norwegian coastal survey) are also used to fill holes.

Weight at age is calculated from the commercial catch back to 1984.

Proportions mature at age from 1984 to 1994 are obtained from the commercial catch data. From 1995-2001 the proportions mature at age are obtained from the Norwegian coastal survey.

Norway is assumed to account for most of the NCC landings. The text table below shows which kind of data are collected:

|  | Kind of data |  |  |  |  |
| :--- | :---: | :---: | :---: | :---: | :---: |
| Country | Caton (catch in <br> weight) | Canum (catch at <br> age in numbers) | Weca (weight at <br> age in the catch) | Matprop <br> (proportion <br> mature by age) | Length <br> composition in <br> catch |
| Norway | X | X | X | X | X |

The result files (FAD data) can be found at ICES and with the stock co-ordinator, either in the IFAP system as SAS datasets or as ASCII files on the Lowestoft format, either under w:\acfm\afwglyearlstock\coas_cod or w: lifapdataleximport $\backslash$ afwglcoas_cod.

## B.2. Biological

Weight at age in the stock is obtained from the Norwegian coastal survey in the period 1995 to 2001. From 1984 to 1994 weight at age in stock is taken from weight at age in the catch because no survey data from this period are available.

A fixed natural mortality of 0.2 is used both in the assessment and the forecast.

Both the proportion of natural mortality before spawning (Mprop) and the proportion of fishing moratlity before spawning (Fprop) are to 0 .

## B.3. Survey

Since 1995 a Norwegian trawl-acoustic survey (Norwegian coastal survey) specially designed for coastal cod has been conducted annually in October-November ( 28 days). The survey covers the fjords and coastal areas from the Varangerfjord close to the Russian border and southwards to $62^{\circ} \mathrm{N}$. The aim of conducting a acoustic survey targeting Norwegian coastal cod has been to support the stock assessment with fishery-independent data of the abundance of both the commercial size cod as well as the youngest pre-recruit coastal cod. The survey therefore covers the main areas where the commercial fishery takes place, normally dominated by 4-7 year old fish.

The 0 - and 1 year-old coastal cod, mainly inhabiting shallow water ( $0-50$ meter) near the coast and in the fjords, are also represented in the survey, although highly variable from year to year. However, the 0 -group cod caught in the survey is impossible to classify to NCC or NEAC by the otoliths since the first winter zone is used in this separation. A total number of more than 200 trawl hauls are conducted during the survey ( 100 bottom trawl, 100 pelagic trawl).

The survey abundance indexes at age are total numbers (in thousands) computed from the acoustics.
Ages 2-8 are used in the XSA-tuning.

## B.4. Commercial CPUE

No commercial CPUE are available for this stock.

## B.5. Other relevant data

None

## C. Historical stock development

Model used: XSA

Software used: IFAP / Lowestoft VPA suite

Model Options chosen:
Tapered time weighting applied, power $=3$ over 20 years

Catchability independent of stock size for all ages

Catchability independent of age for ages $>=8$
Survivor estimates shrunk towards the mean F of the final 2 years or the 4 oldest ages
S.E. of the mean to which the estimate are shrunk $=1.0$

Minimum standard error for population estimates derived from each fleet $=0.300$

## Prior weighting not applied

Input data types and characteristics:

| Type | Name | Year range | Age range | Variable from year to year Yes/No |
| :---: | :---: | :---: | :---: | :---: |
| Caton | Catch in tonnes | 1984 - last data year | 2-10+ | Yes |
| Canum | Catch at age in numbers | 1984 - last data year | 2-10+ | Yes |
| Weca | Weight at age in the commercial catch | 1984 - last data year | $2-10+$ | Yes |
| West | Weight at age of the spawning stock at spawning time. | 1984 - last data year | $2-10+$ | Yes/No - assumed to be the same as weight at age in the catch from 19841994 |
| Mprop | Proportion of natural mortality before spawning | 1984 - last data year | 2-10+ | No - set to 0 for all ages in all years |
| Fprop | Proportion of fishing mortality before spawning | 1984 - last data year | $2-10+$ | No - set to 0 for all ages in all years |
| Matprop | Proportion mature at age | 1984 - last data year | $2-10+$ | Yes |
| Natmor | Natural mortality | 1984 - last data year | $2-10+$ | No - set to 0.2 for all ages in all years |

## D. Short-term projection

Model used: Age structured
Software used: MFDP- prediction with management option table and MFYPR- yield per recruit.
Initial stock size. Taken from the XSA for age 3 and older. The recruitment at age 2 in intermediate year is estimated using the RCT-3 software and indices from the Norwegian Acoustic survey. The same recruitment is used for age 2 in all projection years.

Natural mortality: Set to 0.2 for all ages in all years
Maturity: Same as previous year.
F and M before spawning: Set to 0 for all ages in all years
Weight at age in the stock: Same as previous year.

Weight at age in the catch: Same as two years ago.
Exploitation pattern: Average of the three last years, scaled by the Fbar (4-7) to the level of the last year Intermediate year assumptions: F status quo

Procedures used for splitting projected catches: Not relevant

## E. Medium-term projections

Not done.

## F. Long-term projections

Not done.

## G. Biological reference points

## A. General

## A. 1 Stock definition

Greenland halibut (Reinhardtius hippoglossoides, Walbaum) is distributed in the Arctic and boreal waters in the North Atlantic and in the North Pacific (Fedorov 1971; Godø and Haug 1989; Bowering and Brodie 1995; Bowering and Nedreaas 2000). In the northeastern Atlantic the distribution is more or less continuous along the continental slope from the Faeroe Islands and Shetland to north of Spitsbergen (Whitehead et al. 1986; Godø and Haug 1989; Nizovtsev, 1989), with the highest concentrations from 500 to 800 m depth between Norway and Bear Island, which is also regarded as the main spawning area (Nizovtsev, 1968; Godø and Haug 1987; Albert et al. 2001b). Peak spawning occurs in December in the main spawning area, but also in nearby localities during summer (Nizovtsev, 1989; Albert et al. 2001b). Atlantic currents transport eggs and larvae northwards and the juveniles are distributed around Svalbard and in the northeastern Barents Sea, to the waters around Franz Josef Land and Novaja Zemlya area (Borkin, 1983; Nizovtsev, 1983; Godø and Haug 1987; Godø and Haug 1989; Albert et al. 2001a). As they grow older they gradually move southwards and eventually alternate between the spawning area and feeding areas in the central-western Barents Sea (Nizovtsev, 1989).

The Northeast arctic Greenland halibut stock is a pragmatically defined management unit. The degree of exchange with other stocks is not resolved, but is believed to be low. Potential routes of exchange may be drift of larvae towards Greenland and migration of adults between the Barents Sea and the Iceland-Faeroe Islands area.

## A. 2 Fishery

Before the mid 1960s the fishery for Greenland halibut was mainly a coastal long line fishery off the coasts of eastern Finnmark and Vesterålen in Norway. The annual catch of the coastal fishery was about $3,000 \mathrm{t}$. In recent years this fishery has landed $3,000-6,000 \mathrm{t}$ although now gillnets are also used in the fishery. In 1964 dense Greenland halibut concentrations were found by Soviet trawlers in the slope area to the west of the Bear Island (Nizovtsev, 1989). Following the introduction of international trawlers in the fishery in the mid 1960s, the total landings increased to about $80,000 \mathrm{t}$ in the early 1970s. The total Greenland halibut landings decreased steadily to about $20,000 \mathrm{t}$ during the early 1980s. This level was maintained until 1991, when the catch increased sharply to $33,000 \mathrm{t}$. From 1992 total landings varied between 9000-19 000 t with a peak in 1999 .

From 1992 the fishery has been regulated by allowing only the long line and gillnet fisheries by vessels smaller than 28 m to be directed for Greenland halibut. This fishery is also regulated by seasonal closure. Target trawl fishery has been prohibited and trawl catches are limited to bycatch only. From 1992 to autumn 1994 bycatch in each haul was not to exceed $10 \%$ by weight. In autumn 1994 this was changed to $5 \%$ bycatch of Greenland halibut onboard at any time. In autumn 1996 it was changed to $5 \%$ bycatch in each haul, and from January 1999 this percentage was increased to $10 \%$. In August 1999 it was adjusted further to $10 \%$ in each haul but only $5 \%$ of the landed catch. From 2001 the bycatch regulations again was changed to $12 \%$ in each haul and $7 \%$ of the landed catch.

The regulations enforced in 1992 reduced the total landings of Greenland halibut by trawlers from 20,000 to about $6,000 \mathrm{t}$. Since then and until 1998 annual trawler landings have varied between 5,000 and $8,000 \mathrm{t}$ without any clear trend attributable to changes in allowable bycatch. However, the increase of trawler landings in 1999 to 10000 t may be attributable partly to the less restrictive bycatch regulations. Landings of Greenland halibut from the directed longline and gillnet fisheries have also increased in recent years to well above the level of $2,500 \mathrm{t}$ set by the Norwegian authorities. This is attributed to the increased difficulties of regulating a fishery that only lasts for a few weeks.

## A. 3 Ecosystem aspects

As investigations show, among the variety of fish, seabirds and marine mammals Greenland halibut were found in the diet of just three species - Greenland shark (Somniosus microcephalus), cod (Gadus morhua morhua) and Greenland halibut itself. Besides, killer whale (Orcinus orca), grey seal (Halichoerus grypus) and narwhal (Monodon monoceros) could be its potential predators. However, the presence of Greenland halibut in the diet of the above species was minor. Predators fed mainly on juvenile Greenland halibut up to $30-40 \mathrm{~cm}$ long.

The mean annual percentage of Greenland halibut in cod diet in 1984-1999 constituted $0,01-0,35 \%$ by weight $(0,05 \%$ in average) (DOLGOV \& SMIRNOV 2001). Low levels of consumption are related to the distribution pattern of juvenile Greenland halibut as they spend the first years of the life mainly in the outlying areas of their distribution, in the northern Barents Sea, where both adult Greenland halibut and other abundant predator species are virtually absent.

Cannibalism was the highest in 1960's (up to $1,2 \%$ by frequency of occurrence). During the 1980 's, in the Greenland halibut stomachs the frequency of occurrence of their own juveniles did not exceed $0,1 \%$. During the 1990's, the portion of their own juveniles (by weight) was at the level of $0,6-1,3 \%$.

Food composition of the Greenland halibut in the Barents Sea includes more than 40 prey species (NIzovtsev 1989; DOLGOV \& SMIRNOV 2001). Investigations over a wide area of the continental slope up to the Novaya Zemlya show that the main food source of Greenland halibut consists of fish, mostly capelin (Mallotus villosus villosus) and polar cod (Boreogadus saida) followed by cephalopods and shrimp (Pandalus borealis). During the 1990's an important component of the diet was waste products from fisheries for other species (heads, guts etc.). With growth, a decrease in the importance of small food items (shrimp, capelin) in Greenland halibut diet and the increase of a portion of large fish such as cod and haddock (Melanogrammus aeglefinus) were observed.

With the Greenland halibut stock being nearly 100000 tonnes, the total food consumption of the population is estimated to be about 280000 tonnes. The biomass of commercial species consumed (shrimp, capelin, herring, polar cod, cod, haddock, redfish (Sebastes sp.), long rough dab (Hippoglossoides platessoides) does not exceed 5000-10 000 tonnes per species (DOLGOV \& SMIRNOV 2001).

The Greenland halibut as a species thus has a negligible effect on the other commercial species in the Barents Sea both as predator and prey.

Greenland halibut occurs over a wide range of depths (from 20 to 2200 m ) and temperatures (from -1.5 to $10^{\circ} \mathrm{C}$ ) (BoJE \& Hareide, 1993; Shuntov, 1965; Nizovtsev, 1989). Young Greenland halibut occur mostly in the northeastern Barents Sea (Spitsbergen archipelago and further east to Franz Josef Land) where the presence adult Greenland halibut or other predators appears minimal. Therefore, Greenland halibut mortality after settling in the area is low and stable and driven mainly by envionmental factors.

## B Data

## B. 1 Commercial catch

Norwegian commercial catch in tonnes by quarter, area and gear are derived from the sales notes statistics of the Directorate of Fisheries. Data from about 20 sub areas are aggregated on 6 main areas for the gears gill net, long line, bottom trawl and shrimp trawl. For bottom trawl the quarterly area distribution of the catches is adjusted by logbook data from The Directorate of Fisheries and the total bottom trawl catch by quarter and area is adjusted so that the total annual catch for all gears is the same as the official total catch reported to ICES. No discards are reported or accounted for in the catch statistics.

Russian catch based on daily reports from the vessels are combined in the statistics of the All-Russian Research Institute of Fisheries and Oceanography (VNIRO, Moscow). Data are provided separately by ICES areas and gears.

The sampling strategy is to have age-length samples from all major gears in each area and quarter. There are at present no defined criteria on how to allocate samples of catch numbers, mean length and mean weight at age to unsampled catches, but the following general process has been applied: First look for samples from a neighbouring area if the fishery extends to this area in the same quarter. If there are no samples available in neighbouring areas, search for samples from other gears with the most similar selectivity in the same area or in neighbouring areas. The last option is to search in neighbouring quarters, first from the same gear in the same area, and then from neighbouring areas and similar gears. ALKs from research surveys (shrimp trawl) are also used to fill gaps in age sampling data.

Norway and Russia, on average, have accounted for about $90-95 \%$ of the Greenland halibut landings during more recent years. Data on catch in tonnes from other countries are either taken from ICES official statistics (by ICES area) or from reports to Norwegian authorities. A few countries also supply some additional data. The text table below indicates the type of data provided by country:

|  | Kind of data |  |  |  |  |
| :--- | :---: | :---: | :---: | :---: | :---: |
| Country | Caton (catch in <br> weight) | Canum (catch at <br> age in numbers) | Weca (weight at <br> age in the catch) | Matprop <br> (proportion <br> mature by age) | Length <br> composition in <br> catch |
| Norway | x | x | x | x | x |
| Russia | x | x | x | x |  |

As reported to Norwegian authorities

The Norwegian input files are Excel spreadsheet files, while the Russian input data are supplied on paper and later input to Excel spreadsheet files before aggregation to international data. The data are archived in the national laboratories and with the Norwegian stock co-ordinator.

The national data have been aggregated with international data on Excel spreadsheet files. The Russian length composition has been applied to Russian landings together with an age-length-key (ALK) and weight at age data from the Norwegian landings. Catches from the other countries were assumed to have the same age composition and weight at age as the Norwegian landings. The Excel spreadsheet files used for age distribution, adjustments and aggregations are held by the Norwegian stock co-ordinator and for the current and previous year in the ICES computer system under $\mathbf{w}: \backslash \mathbf{a c f m} \backslash \mathbf{a f w g} \mid$ yearlpersonal\name (of stock co-ordinator).

The result files (FAD data) can be found at ICES and with the stock co-ordinator, either in the IFAP system as SAS datasets or as ASCII files on the Lowestoft format, under w: $\mathbf{\text { acfm }} \backslash \mathbf{a f w g} \backslash \mathbf{y e a r} \backslash$ data $\backslash \mathbf{g r h} \_$arct.

## B. 2 Biological

For 1964-1969, separate weight at age data are used for the Norwegian and the Russian catches. Both data sets are mean values for the period and are combined as a weighted average for each year. A constant set of weight-at-age data is used for the total catches in 1970-1978. For subsequent years annual estimates are used. The mean weight at age in the catch is calculated as a weighted average of the weight in the catch from Norway and Russia. The weight at age in the stock is set equal to the weight at age in the catch for all years.

A fixed natural mortality of 0.15 is used both in the assessment and the forecast.

Both the proportion of natural mortality before spawning (Mprop) and the proportion of fishing mortality before spawning (Fprop) are set to 0 .

Annual ogives based on sexes combined using Russian survey data are given for the years 1984-1990 and 1992-last data year. An average ogive derived from 1984-1987 is used for 1964-1983. For 1984 to the last data year a three-year running average is used.

## B. 3 Surveys

The results from the following research vessel survey series are evaluated by the Working Group:

1. Norwegian bottom trawl survey in August in the Barents Sea and Svalbard from 1984 in fishing depths of less than 100 m and down to 500 m . (Table E1 and E2).
2. Norwegian Greenland halibut surveys in August from 1994. The surveys cover the continental slope from 68 to $80^{\circ} \mathrm{N}$, in depths of $400-1500 \mathrm{~m}$ north of $70^{\circ} 30^{\prime} \mathrm{N}$, and $400-1000 \mathrm{~m}$ south of this latitude. This series has in 2000 been revised to also include depths between $400-500 \mathrm{~m}$ in all years (Table E3).
3. Norwegian bottom trawl surveys east and north of Svalbard in autumn from 1996 (Table E4).
4. The Norwegian Combined Survey index Table E5, combination of the results from Tables E1-E4.
5. Russian bottom trawl surveys in the Barents Sea from 1984 in fishing depths of $100-900 \mathrm{~m}$. This series has been revised substantially since the 1998 assessment in order to make the years more comparable with respect to area coverage and gear type (Table E6).
6. Spanish bottom trawl survey in the slope of Svalbard area in October, ICES Division IIb: from 1997 (Table E7).
7. Norwegian Barents Sea bottom trawl survey (winter) from 1989 in fishing depths of less than 100 m and down to 500 m . In order to utilise the last year values in the VPA calibration, this series was adjusted back by one year and one age group to reflect sampling as if it occurred in the autumn of the previous year (Table E8).
8. International pelagic 0 -group surveys from 1970. (Table A14).

Over the last several years the Working Group has been concerned about trends in catchability within individual surveys used for tuning of the XSA. The trends were seen for younger ages of year classes in the late 80 's and early 90 's that were initially estimated to be very low in abundance. With increasing age these year classes were estimated to be much closer to the mean abundance. In previous meetings the Working Group therefore increased the lower age used in tuning to five years in order to reduce the problem. This only partly resolved the problem though, and in all subsequent assessments estimated recruitment of the last 2-3 years has increased from one year to the next.

The Norwegian bottom trawl survey in the Barent Sea and Svalbard catch Greenland halibut mainly in the range of ages 18 , although in most years age 1 is poorly represented and all age group younger than five years are not considered to be well represented in this survey due to the limited depth range covered. The relative strength of the year classes varies considerably with age. In more recent years there has been low but somewhat better representation of young fish in this survey.

The Norwegian juvenile Greenland halibut survey north and east of Svalbard were started in 1996 and from 2000 this survey is conducted as a joint survey between Norway and Russia. As a result it is expected that the area coverage will improve, better representing the distribution of juveniles and will provide a more comparable time series. Only the Norwegian part of these northern surveys is currently included in the Norwegian Combined Survey index (see below) . In future, when the extended coverage in the Russian zone has been repeated for at least five years the Working Group will consider revising the combined index.

The Norwegian Greenland halibut survey along the deep continental slope south and west of Spitsbergen began in 1994. Although Greenland halibut older than 15 years are caught, few fish are represented in the catch over age 12 or less than age 5 (Table E4). Most of the abundance indices are dominated by ages 5-8.

Most of the surveys considered by the Working Group in 2002 cover either the adult population in the slope area or juvenile distribution in northern areas. The problem of underestimation of recruitment in the last few years included in the analyses has been attributed to shortcomings in survey coverage. The Working Group at previous meetings has noted the need for annual surveys that sample most of the population within a short period of time. Prior to the 2002 WG meeting effort was therefore made to combine some of these surveys into a new total index. The new index is termed the Norwegian Combined Survey Index and is established back to 1996, the first year with survey coverage northeast of Svalbard. It includes bottom trawls from the Norwegian bottom trawl survey in August in the Barents Sea and Svalbard (Tables E1 and E2), the Norwegian Greenland halibut survey in August along the continental slope (Table E3), and the Norwegian bottom trawl survey in August-September north and east of Svalbard (Table E4). Prior to the meeting in 2003 work was done to evaluate the combination of these survey series into one index and this was reported in Working Document 5 to the Working Group. Based on these results it was decided to use this combined index in this years assessment.

The Norwegian Combined Survey Index (Table E5) indicates a significant increase in the total stock during the last three years and a stock size in 2002, nearly $40 \%$ above last years index. However, there is no clear year class pattern in the data and some ages are consistently underestimated relative to adjacent age groups (e.g. age 9 and partly age 4). The highest indices were observed for age seven, with exception of the two last years when age 1 was most abundant. That indicates that
the catchability of younger ages (i.e. those primarily from northern surveys) are not comparable with the older ones (i.e. those primarily from the slope). This is probably a result of pooling different surveys using different gears. These weaknesses reduce the applicability of the combined surveys, and the Working Group advises that further work be done to improve the combined index in the future.

The Russian Barents Sea bottom trawl survey, which extends back to 1984 catch fish mainly in the range of 4-10 years old. The relative abundance of the year classes against age is similar to the surveys above. This survey covers the Barents Sea including the continental slope of the Norwegian Sea. Total abundance indices from this survey show trend to grow since 1996.

The Spanish bottom trawl surveys along the continental slope north of $73^{\circ} 30^{\prime} \mathrm{N}$ from 1997 (Table E7) differ from the other survey series indicating reduced abundance in this area since 1999.

The Norwegian bottom trawl survey during winter in the Barents Sea catch Greenland halibut older than 12 years, but are not particularly effective in catching fish older than 7 years. This is likely due to the limited depth distribution of the survey area. Nevertheless, the survey appears very effective at catching Greenland halibut up to age 6 . The relative abundance of the year classes against age is comparable with the survey above.

The strengths of the Greenland halibut year classes of 1970-1997 from the International pelagic 0-group surveys in the Barents Sea are shown in Table A14. The results are highly variable over the time period. However, most of the 1970's and 1980's year classes are represented in reasonably high numbers. In recent years the 1988-1992 and the 1996 year classes have been well below the long term average. The 1993-1995 and 1997-1999 year classes are closer to the average. Significant increase of 0-group abundance indices with compare to previous years was observed in 2000-2002.

All in all, the surveys seem to indicate that the catchability of the 1990-1995 year classes increased considerably as the fish becomes five years and older. Based on extremely low catch rates in the surveys, these year classes were considered very poor in previous assessments by the Working Group, but improved considerably at older ages. The reason for this change in catchability is not clear. However, it is known that important areas for young Greenland halibut may be found north and east of Svalbard (Table E4). Albert et al. (2001a) showed that the south-western end of the distribution area of age 1 fish was gradually displaced northwards along west Spitsbergen in the period 1989-92 and southwards in the period 1994-1996. These displacements corresponded to changes in hydrography and may be explained by increased migration of the 19901995 year classes to areas outside the survey area.

## B. 4 Commercial CPUE

The restrictive regulations imposed on the trawl fishery after 1991 disrupted the traditional time series of commercial CPUE data. However, an attempt to continue the series was made through a research program using two Norwegian trawlers in a limited commercial fishery (Tables 8.6 and E9). This comprises fishing during two weeks in May-June and October, representing an effort somewhat less than $20 \%$ of the 1991 level. Since 1994 the fishery has been restricted to May-June. This fishery was conducted, as much as possible, in the same way as the commercial fishery in the previous years. Since 1997 also two Russian trawlers conducted a limited research fishery for Greenland halibut.

The CPUE from the experimental fishery was found, however, to be considerably higher than in the traditional fishery and has exhibited an increasing trend from 1992-1996. After 1996 the Norwegian CPUE series has varied between 1200 and $1650 \mathrm{~kg} / \mathrm{h}$ with the highest value in 2000 (Table E9). The Russian experimental CPUE series shows an increasing trend since 1997, and this series also shows the highest value in 2000.

## B. 5 Other relevant data

None

## C. Historical stock development

Model used: XSA

Software used: IFAP / Lowestoft VPA suite

Model Options chosen:

Tapered time weighting applied, power $=3$ over 20 years
Catchability independent of stock size for all ages
Catchability independent of age for ages $>=10$
Survivor estimates shrunk towards the mean F of the final 2 years or the 5 oldest ages
S.E. of the mean to which the estimate are shrunk $=0.500$

Minimum standard error for population estimates derived from each fleet $=0.300$

Prior weighting not applied
Input data types and characteristics:

| Type | Name | Year range | Age range | Variable from year to <br> year <br> Yes/No |
| :--- | :--- | :--- | :--- | :--- |
| Caton | Catch in tonnes | 1964 - last data year | - (total) | Yes |
| Canum | Catch at age in <br> numbers | 1964 - last data year | $5-15+$ | Yes |
| Weca | Weight at age in the <br> commercial catch | 1964 - last data year | $5-15+$ | Yes/No - constant at <br> age from 1964-1978 |
| West | Weight at age of the <br> spawning stock at <br> spawning time. | 1964 - last data year | $5-15+$ | Yes/No - assumed to <br> be the same as <br> weight at age in the <br> catch |
| Mprop | Proportion of natural <br> mortality before <br> spawning | 1964 - last data year | $5-15+$ | No - set to 0 for all <br> ages in all years |
| Fprop | Proportion of fishing <br> mortality before <br> spawning | 1964 - last data year | $5-15+$ | No - set to 0 for all <br> ages in all years |
| Matprop | Proportion mature at <br> age | 1964 - last data year | $5-15+$ | Yes/No - three year <br> running <br> constant at age from, <br> $1964-1983$ |
| Natmor | Natural mortality | 1964 - last data year | $5-15+$ | No - set to 0.15 for <br> all ages in all years |

Tuning data:

| Type | Name | Year range | Age range |
| :--- | :--- | :--- | :--- |
| Tuning fleet 1 | Norwegian <br> Combined survey <br> index | 1996 - last data year | $5-15+$ |
| Tuning fleet 2 | Norwegian <br> experimental CPUE | 1992 - last data year | $5-14$ |
| Tuning fleet 3 | Russian trawl survey <br> from 1992 | 1992 - last data year | $5-15+$ |

## D. Short-term projection

Model used: Age structured
Software used: IFAP prediction with management option table and yield per recruit routines
Initial stock size. Taken from the XSA for age 6 and older. The recruitment at age 5 in the last data year is estimated using the mean from 1990 to two years before the last data year following the argument that recruitment at age 5 shows a sharp reduction in the most recent years in the previous assessments, which is not believed to reflect the true recruitment.

Natural mortality: Set to 0.15 for all ages in all years
Maturity: The same ogive as in the assessment is used for all years
$F$ and $M$ before spawning: Set to 0 for all ages in all years
Weight at age in the stock: Average weight at age for the last three years used in the assessment
Weight at age in the catch: Average weight at age for the last three years used in the assessment
Exploitation pattern: Average of the three last years
Intermediate year assumptions: Catch constraint

Stock recruitment model used: Constant recruitment as described earlier

Procedures used for splitting projected catches: Not relevant

## E. Medium-term projections

Not done

## A. General

## A.1. Stock definition

The North-East Arctic saithe is mainly distributed along the coast of Norway from the Kola peninsula in northeast and south to Møre at $62^{\circ} \mathrm{N}$. The 0 -group saithe drifts from the spawning grounds to inshore waters. 2-3 years old the saithe gradually moves to deeper waters, and at age 3-6 it is found at typical saithe grounds. It starts to mature at age 5-7, and in early winter a migration towards the spawning grounds further out and south starts.

The stock boundary $62^{\circ} \mathrm{N}$ is more for management purposes than a biological basis for stock separation. Tagging experiments show a regular annual migration of mature fish from the North-Norwegian coast to the spawning areas off the west coast of Norway and also to a lesser extent to the northern North Sea (ICES 1965). There is also a substantial migration of immature saithe to the North Sea from the Norwegian coast between $62^{\circ}$ and $66^{\circ} \mathrm{N}$ (Jakobsen 1981). In some years there are also examples of mass migration from northern Norway to Iceland and to a lesser extent to the Faroe Islands (Jakobsen 1987). 0-group saithe, on the other side, drifts from the northern North Sea to the coast of Norway north of $62^{\circ} \mathrm{N}$.

## A.2. Fishery

Since the early 1960 s the fishery has been dominated by purse seine and trawl fisheries accounting for $60 \%$ in 2000 . A traditional gill net fishery for spawning saithe accounts for about $22 \%$. The remaining catches are taken by Danish seine and hand line in addition to minor by-catches in the long line fishery for other species. Some changes in recent regulations have led to fewer amounts taken by purse seine. Catches declined sharply after 1976. This was partly caused by the introduction of national economic zones in 1977. The stock was accepted as exclusively Norwegian and quota restrictions were put on fishing by other countries while the Norwegian fishery for some years remained unrestricted. In recent years the purse seine and trawl fisheries have been regulated by quotas where account has been taken of expected landings from other gears. Quotas can be transferred between purse seine and trawl fisheries if the quota allocated to one of the gears will not be taken. The target set for the total landings has generally been consistent with the scientific recommendations. Norway presently accounts for about $93 \%$ of the landings.

The number of vessels taking part in the purse seine fishery has varied between 112 and 429 since 1977, with the highest participation in the first part of the period. There have been some variations from year to year, and many of the vessels that have taken part in the fishery the last decade have accounted for only a small fraction of the purse seine catches. The annual effort in the Norwegian trawl fishery has varied between 12000 and 77000 hours, with the highest effort from 1989 to 1995. Like in the purse seine fishery there have been rather large changes from year to year.

1 March 1999 the minimum landing size was increased from $35-40 \mathrm{~cm}$ to 45 cm for trawl and conventional gears, and to 42 cm (north of Lofoten) and 40 cm (between $62^{\circ} \mathrm{N}$ and Lofoten) for purse seine, with an exception for the first 3000 t purse seine catch between $62^{\circ} \mathrm{N}$ and $65^{\circ} 30 \mathrm{~N}$, where the minimum landing size still is 35 cm .

## A.3. Ecosystem aspects

The recruitment of saithe may suffer in years with reduced inflow of Atlantic water (Jakobsen 1986).

## B. Data

## B.1. Commercial catch

Norwegian commercial catch in tonnes by quarter, area and gear are derived from the sales notes statistics of The Directorate of Fisheries. Data from about 20 sub areas are aggregated on 6 main areas for the gears gill net, long line, hand line, purse seine, Danish seine, bottom trawl, shrimp trawl and trap. For bottom trawl the quarterly area distribution of the catches is adjusted by logbook data from The Directorate of Fisheries and the total bottom trawl catch by quarter and area is adjusted so that the total annual catch for all gears is the same as the official total catch reported to ICES. No discards are reported or accounted for, but there are several reports of discards. In later years there are also reports of misreporting, saithe is landed as cod in a period with decreasing quotas and availability of cod and good availability of saithe.

The sampling strategy is to have age-length samples from all major gears in each area and quarter. There are at present no defined criteria on how to allocate samples of catch numbers, mean length and mean weight at age to unsampled catches, but the following general process has been applied: First look for samples from a neighbouring area if the fishery extends to this area in the same quarter. If there are no samples available in neighbouring areas, search for samples from other gears with the most similar selectivity in the same area or in neighbouring areas. The last option is to search in neighbouring quarters, first from the same gear in the same area, and than from neighbouring areas and similar gears. For some gears, areas and quarters length samples taken by the coast guard are applied and combined with an ALK from a neighbouring area, gear or quarter. ALKs from research surveys (shrimp trawl) are also used to fill holes.

Constant weight at age values is used for the period 1960 - 1979. For subsequent years, Norwegian weights at age in the catch are estimated from length at age by the formula:

$$
\text { weight }(\mathrm{kg})=\left(1^{3} * 5.0+\mathrm{l}^{2} * 37.5+\mathrm{l}^{*} 123.75+153.125\right) * 0.0000017
$$

where

$$
1=\text { length in } \mathrm{cm} .
$$

Norway have on average accounted for about $95 \%$ of the saithe landings. Data on catch in tonnes from other countries are either taken from ICES official statistics (by ICES area) or from reports to Norwegian authorities. A few countries also supply some additional data. The text table below shows which country supply which kind of data:

|  | Kind of data |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: |
| Country | Caton (catch in weight) | Canum (catch at age in numbers) | Weca (weight at age in the catch) | Matprop (proportion mature by age) | Length composition in catch |
| Norway | x | x | x | x | x |
| Russia | x |  |  |  | x |
| Germany | x | x | x |  |  |
| United Kingdom | x |  |  |  |  |
| France ${ }^{1}$ | X |  |  |  |  |
| Spain ${ }^{1}$ | x |  |  |  |  |
| Portugal ${ }^{1}$ | x |  |  |  |  |
| Ireland ${ }^{1}$ | X |  |  |  |  |
| Greenland ${ }^{1}$ | X |  |  |  |  |
| Faroe Islands ${ }^{1}$ | X |  |  |  |  |
| Iceland ${ }^{1}$ | x |  |  |  |  |

${ }^{1}$ As reported to Norwegian authorities

The Norwegian, Russian and German input files are Excel spreadsheet files. Russian input data earlier than 2002 are supplied on paper and later punched into Excel spreadsheet files before aggregation to international data. The data should be found in the national laboratories and with the Norwegian stock co-ordinator.

The national data have been aggregated to international data on Excel spreadsheet files. Age composition data for 2002 was available from Norway, Russia (Sub-area I and Division IIA) and Germany (Division IIA). Generally the Russian length composition has been applied on the Russian landings together with an age-length-key (ALK) and weight at age
data from the Norwegian trawl landings. In 2002 Russian length compositions were available for Division IIB, and were applied on the Russian landings together with an age-length-key from the Norwegian trawl landings. Catches from the other countries were assumed to have the same age composition and weight at age as the Norwegian trawl landings. In some years the final German and Russian numbers at age have been adjusted to remove SOP discrepancies before aggregation to international data. The Excel spreadsheet files used for age distribution, adjustments and aggregations can be found with the Norwegian stock co-ordinator and for the current and previous year in the ICES computer system under w:\acfm\afwglyear>personal\name (of stock co-ordinator).

The result files (FAD data) can be found at ICES and with the stock co-ordinator, either in the IFAP system as SAS datasets or as ASCII files on the Lowestoft format, either under w:\acfm $\backslash \mathbf{a f w g}|\mathbf{y e a r} \backslash \mathbf{S t o c k}| \mathbf{s a i}$ arct or w: lifapdataleximportlafwglsai_arct.

## B.2. Biological

Weight at age in the stock is assumed to be the same as weight at age in the catch.
A fixed natural mortality of 0.2 is used both in the assessment and the forecast.
Both the proportion of natural mortality before spawning (Mprop) and the proportion of fishing mortality before spawning (Fprop) are set to 0 .

Regarding the proportion mature at age, until 1995 knife-edge maturity at age 6 was used for this stock. When data on spawning zones recorded in otoliths in Norway were investigated, no evidence of change in maturation rates over the period in the assessment was found and it was decided to use the same ogive for all years. This ogive is based on the distribution of age at first spawning among 8 year and older fish. It represents an approximation of the data from 1973 to 1994 , with most weight given to recent observations.

## B.3. Surveys

Since 1985 a Norwegian acoustic survey specially designed for saithe has been conducted annually in OctoberNovember (Nedreaas 1997). The survey covers the near coastal banks from the Varangerfjord close to the Russian border and southwards to $62^{\circ} \mathrm{N}$. The whole area has been covered since 1992, and the major parts since 1988. The aim of conducting an acoustic survey targeting Northeast Arctic saithe has been to support the stock assessment with fishery-independent data of the abundance of the youngest saithe. The survey mainly covers the grounds where the trawl fishery takes place, normally dominated by 3-5(6) year old fish. 2-year-old saithe, mainly inhabiting the fjords and more coastal areas, are also represented in the survey, although highly variable from year to year. In 1997 and 1998 there was a large increase in the abundance of age 5 and older saithe, confirming reports from the fishery. In 1999 the abundance of these age groups decreased somewhat, but was still at a high level compared to years before 1997 (Mehl 2000). Abundance indices for ages 2-5 from 1988 and onwards have traditionally been used for tuning, but including older ages as a $6+$ group in the tuning series improved the scaled weights a little and at the 2000 WG meeting it was decided to apply the extended series in the assessment. The results from the survey autumn 2000 showed a further decrease in the abundance of age 5 and older saithe (Korsbrekke and Mehl 2000). It is not known how well the survey covers the oldest age groups from year to year, but at least for precautionary reasons the $6+$ group was kept in the tuning series.

Since 1995 a Norwegian acoustic survey for coastal cod has been conducted along the coast and in the fjords from Varanger to Stad in September, just prior to the saithe survey described above. This survey covers coastal areas not included in the regular saithe survey. Because saithe is also acoustically registered, this survey provides supplementary information, especially about 2- and 3-year-old saithe that have not yet migrated out to the banks. At the WG meeting in 2000 analyses were done on combining these indices with indices from the regular saithe survey in the tuning series, but it did not influence the assessment much. The WG therefore decided, for the time being, to only apply indices from the regular saithe survey in the assessment since this series is longer.

## B.4. Commercial CPUE

Two CPUE data series are used, one from the Norwegian purse seine fishery and one from the Norwegian trawl fishery.

Until 1999 indices of fishing effort in the purse seine fishery was based on the number of vessels of 20-24.9 m length and the effort (number of vessels) of this length category was raised by the catches to represent the total purse seine effort. The number of vessels taking part in the fishery almost doubled from 1997 to 1998, but due to regulations the
catches were almost the same as in 1997. In such a situation the total number of vessels participating in a fishery is perhaps not a good measure of effort. Many of the vessels that have taken part in the fishery the last decade have accounted for only a small fraction of the purse seine catches. Roughly half of the vessels have caught less than 100 tonnes per year, and the sum of these catches represents only about $5-10 \%$ of the total purse seine catch. Therefore the number of vessels catching more than 100 tonnes annually seems to be a more representative and more stable measure of effort in the purse seine fishery. These numbers are raised to the total purse seine catch. The new effort series show a smaller decrease in later years than the old one and in XSA runs it gets higher scaled weights. The 2000 WG meeting therefore decided to use the new CPUE data series in the assessment.

Catch and effort data for Norwegian trawlers were until 2000 taken from hauls where the effort almost certainly had been directed towards saithe, i.e., days with more than $50 \%$ saithe and only on trips with more than $50 \%$ saithe in the catch. The effort estimated for the directed fishery was raised by the catches to give the total effort of Norwegian trawlers. From 1997 to 1998 the effort increased by more than $50 \%$, but due to regulations the catches were slightly lower in 1998 and the CPUE decreased by almost $40 \%$ from 1997 to 1998 and stayed low in 1999. This may at least partly be explained by change in fishing strategies in a period with increasing problems with bycatch of saithe in the declining cod fishery due to good availability of saithe. In 2001 new CPUE indices by age were estimated based on the logbook database of the Directorate of Fisheries, which has a daily resolution (Salthaug and Godø 2000). After some initial analyses it was decided to only include data from vessels larger than the median length since they showed the least noisy trends. One single CPUE observation from a given vessel is the total catch per day divided by the duration of all the trawl hauls that day. To increase the number of observations during a time period with decreasing directed saithe fishery, all days with $20 \%$ or more saithe were included. The effort (hours trawling) for each CPUE observation is standardised or calibrated to a standard vessel. Until 2002, a yearly index was calculated by first averaging all CPUE observations for each month, and then averaging over the year. The CPUE indices were splitted on age groups by quarterly weight, length and age data from the trawl fishery. From 2003, a yearly index is calculated by first averaging all CPUE observations for each quarter, and then averaging over the year. The CPUE indices are finally splitted on age groups by yearly catch in numbers and weight at age data from the trawl fishery. The new approach is less influenced by short periods with poor data, while it still evens out seasonal variations.

Due to rather large negative $\log \mathrm{q}$ residuals in the first part of the new time series, it was shortened to only cover the period after 1993.

## B.5. Other relevant data

None.

## C. Historical Stock Development

## Model used: XSA

Software used: IFAP / Lowestoft VPA suite
Model Options chosen:
Tapered time weighting applied, power $=3$ over 20 years
Catchability independent of stock size for all ages
Catchability independent of age for ages $>=8$
Survivor estimates shrunk towards the mean F of the final 5 years or the 5 oldest ages
S.E. of the mean to which the estimate are shrunk $=0.500$

Minimum standard error for population estimates derived from each fleet $=0.300$
Prior weighting not applied

Input data types and characteristics:

| Type | Name | Year range | Age range | Variable from year to <br> year <br> Yes/No |
| :--- | :--- | :--- | :--- | :--- |
| Caton | Catch in tonnes | 1960 - last data year | $2-11+$ | Yes |
| Canum | Catch at age in <br> numbers | 1960 - last data year | $2-11+$ | Yes |
| Weca | Weight at age in the <br> commercial catch | $1960-$ last data year | $2-11+$ | Yes/No - constant at <br> age from 1960-1979 |
| West | Weight at age of the <br> spawning stock at <br> spawning time. | $1960-$ last data year | $2-11+$ | Yes/No - assumed to <br> be the same as <br> weight at age in the <br> catch |
| Mprop | Proportion of natural <br> mortality before <br> spawning | $1960-$ last data year | $2-11+$ | No - set to 0 for all <br> ages in all years |
| Fprop | Proportion of fishing <br> mortality before <br> spawning | $1960-$ last data year | $2-11+$ | No - set to 0 for all <br> ages in all years |
| Matprop | Proportion mature at <br> age | 1960 - last data year | $2-11+$ | No - the same ogive <br> for all years |
| Natmor | Natural mortality | $1960-$ last data year | $2-11+$ | No - set to 0.2 for all <br> ages in all years |

Tuning data:

| Type | Name | Year range | Age range |
| :--- | :--- | :--- | :--- |
| Tuning fleet 1 | Norway ac survey <br> extended 2000 | 1992 - last data year | $3-6+$ |
| Tuning fleet 2 | Norway purse seine <br> revised 2000 | 1989 - last data year | $3-7$ |
| Tuning fleet 3 | Nor new trawl <br> revised 2001 | 1994 - last data year | $5-9$ |

For analysis of alternative procedures see WG reports from AFWG 1997-2002.

## D. Short-Term Projection

Model used: Age structured

Software used: IFAP prediction with management option table and yield per recruit routines, until 2002.
Software used: MFDP prediction with management option table and yield per recruit routines, MFYPR.
Initial stock size. Taken from the XSA for age 5 and older. The recruitment at age 2 and 3 in the last data year is estimated using RCT3 and the corresponding numbers at age 3 and 4 in the start year of the projection is calculated applying a natural mortality of 0.2 and fishing mortality according to the catches taken of these age groups. For consistency, the WG 2004 used the long-term geometric mean recruitment for age 2 from 1960 to the last year for which the retrospective analyses show some stability in recruitment (e.g. 1997 in the 2004 assessment), for projections.

Natural mortality: Set to 0.2 for all ages in all years
Maturity: The same ogive as in the assessment is used for all years
F and M before spawning: Set to 0 for all ages in all years

Weight at age in the stock: Assumed to be the same as weight at age in the catch

Weight at age in the catch: For weight at age in stock and catch the average of the last three years in the VPA is normally used. In 2004 WG , the estimates of weight-at-age in the catches show a decreasing trend towards 2003, and therefore the 2003 weights at age have been applied in the predictions.

Exploitation pattern: The average of the last three years, scaled by the Fbar (3-6) to the level of the last year if there is a trend.

Intermediate year assumptions: TAC constraint

Stock recruitment model used: None, the long term geometric mean recruitment at age 2 is used

Procedures used for splitting projected catches: Not relevant

## E. Medium-Term Projections

Model used: Age structured

Software used: IFAP single option prediction, until 2002

Software used: MFDP single option prediction
Initial stock size: Same as in the short-term projections.

Natural mortality: Set to 0.2 for all ages in all years
Maturity: The same ogive as in the assessment is used for all years
F and M before spawning: Set to 0 for all ages in all years
Weight at age in the stock: Assumed to be the same as weight at age in the catch
Weight at age in the catch: Same as in the short-term projections.
Exploitation pattern: Same as in the short-term projections.
Intermediate year assumptions: F-factor from the management option table corresponding to the TAC

Stock recruitment model used: None, the long term geometric mean recruitment at age 2 is used
Uncertainty models used: @RISK for excel, Latin Hypercubed, 1000 iterations, fixed random number generator

- Initial stock size: Lognormal distribution, LOGNORM(mean, standard deviation), with mean as in the shortterm projections and standard deviation calculated by multiplying the mean by the external standard error from the XSA diagnostics (except for age 2, see recruitment below)
- Natural mortality: Set to 0.2 for all ages in all years
- Maturity: The same ogive as in the assessment is used for all years
- $F$ and $M$ before spawning: Set to 0 for all ages in all years
- Weight at age in the stock: Assumed to be the same as weight at age in the catch
- Weight at age in the catch: Average weight of the three last years
- Exploitation pattern: Average of the three last years, scaled by the Fbar (3-6) to the level of the last year
- Intermediate year assumptions: F-factor from the management option table corresponding to the TAC
- Stock recruitment model used: Truncated lognormal distribution, TLOGNORM(mean, standard deviation, minimum, maximum), is used for recruitment age 2 , also in the initial year. The long term geometric mean, standard deviation, minimum, maximum are taken from the XSA for the period $1960-4^{\text {th }}$ last year.

## F. Long-Term Projections

## Not done

## G. Biological Reference Points

In 1994 the WG proposed a MBAL of $150,000 \mathrm{t}$, based on the frequent occurrence of poor year classes below this level of SSB. The new maturity ogive introduced in 1995 gave somewhat higher historical SSB estimates. 150,000 t was considered to represent a less restrictive MBAL and $170,000 \mathrm{t}$ was found to correspond better with the arguments used in 1994. The Study Group on the Precautionary Approach to Fisheries Management (SGPAFM, ICES 1998/ACFM:10) also found this to be a suitable level for $\mathrm{B}_{\mathrm{pa}}$. However, based on a visual examination of the stock-recruitment plot ACFM later reduced the $\mathrm{B}_{\mathrm{pa}}$ to $150,000 \mathrm{t}$ (ICES 1998b).
$\mathrm{F}_{0.1}$ and $\mathrm{F}_{\max }$ are estimated by the MFDP yield per recruit routine, and increased from 0.08 to 0.11 and from 0.14 to 0.24 for $\mathrm{F}_{0.1}$ and $\mathrm{F}_{\text {max }}$, respectively, in the 1999-2003 assessments.

The SGPAFM (ICES 1998/ACFM:10) suggested the limit reference point $\mathrm{F}_{\text {lim }}=\mathrm{F}_{\text {med }}$ for Northeast Arctic cod, haddock and saithe. A precautionary fishing mortality $\left(\mathrm{F}_{\mathrm{pa}}\right)$ was defined as $\mathrm{F}_{\mathrm{pa}}=\mathrm{F}_{\text {lim }} \cdot \mathrm{e}^{-1.645 \sigma}(\sigma=0.2-0.3)$. The 1998 WG, however, found that setting $\mathrm{F}_{\text {lim }}=\mathrm{F}_{\text {med }}$ did not correspond very well with the exploitation history for those fish stocks. It was therefore decided to estimate $\mathrm{F}_{\mathrm{pa}}$ and other reference points by the PASoft program package (MRAG 1997). The estimates for $\mathrm{F}_{0.1}, \mathrm{~F}_{\text {max }}$, and $\mathrm{F}_{\text {med }}$ were exactly the same as the values already estimated by other routines. The median value for $\mathrm{F}_{\text {loss }}$ was estimated at 0.43 . $\mathrm{F}_{\text {lim }}$ can be set at $\mathrm{F}_{\text {loss }}$ (ICES 1998/ACFM:10). The probability of exceeding $\mathrm{F}_{\text {lim }}$ should be no more than $5 \%$ (ICES 1997/Assess: 7). The $5^{\text {th }}$ percentile of the $\mathrm{F}_{\text {loss }}$ estimated here was 0.30 and the 1998 WG recommended using this value for $\mathrm{F}_{\mathrm{pa}}$. ACFM considered the $5^{\text {th }}$ percentile calculated from the PASoft program package to be too unstable for long term use and re-estimated $F_{p a}$ using the formula $F_{p a}=F_{\text {lim }} \cdot e^{-1.645 \sigma}$ with $\sigma=0.3$ giving a $\mathrm{F}_{\mathrm{pa}}=0.26$, based on an estimated $\mathrm{F}_{\text {lim }}=0.45$ (ICES 1998c). An updated version of the PASoft program package (CEFAS 1999) was available at the 1999 WG and $\mathrm{F}_{\mathrm{pa}}$ was re-estimated to 0.26 . The WG therefore agreed to use this value for a precautionary fishing mortality for saithe ( $\mathrm{F}_{\mathrm{pa}}=0.26$ ).

Recent increments in minimum landing size and an improved exploitation pattern indicate that the PA fishing mortality reference point $\left(\mathrm{F}_{\mathrm{pa}}\right)$ should be re-estimated in the near future.

# Standard Procedure for Assessment XSA/ICA Type 

Stock specific documentation of standard assessment procedures used by ICES.

Stock: North-East Arctic Cod<br>Working Group: Arctic Fisheries Working Group<br>Date:<br>20-02-02

## A. General

## A. 1 Stock definition

The North-East Arctic cod (Gadus morhua) is distributed in the Barents Sea and adjacent waters, mainly in waters above $0^{\circ}$ Celsius. The main spawning areas are along the Norwegian coast between $\mathrm{N} 67^{\circ} 30^{\prime}$ and $70^{\circ}$. The 0 -group cod drifts from the spawning grounds eastwards and northwards and during the international 0 -group survey in august it is observed over wide areas in the Barents Sea.

## A. 2 Fishery

The fishery for North-east Arctic cod is conducted both by an international trawler fleet operating in offshore waters and by vessels using gillnets, longlines, handlines and Danish seine operating both offshore and in the coastal areas. $60-80 \%$ of the annual landings are from trawlers. Catch quotas were introduced in the trawl fishery in 1978 and for the fisheries with conventional gears in 1989. In addition to quotas the fisheries are regulated by mesh size limitations including sorting grids, a minimum catching size, a maximum by-catch of undersized fish, maximum by-catch of nontarget species, closure of areas with high densities of juveniles and by seasonal and area restrictions. Since January 1997 sorting grids have been mandatory for the trawl fisheries in most of the Barents Sea and Svalbard area. Discarding is prohibited. The minimum catching size of cod is 42 cm in the Russian Economic zone, 47 cm in Norwegian Economic zone; both minimum landing sizes are used by respective fleets in the Svalbard area pursuant to the Svalbard Treaty 1920). The fisheries are controlled by inspections at sea, requirement of reporting to catch control points when entering and leaving the EEZs and by inspections when landing the fish for all fishing vessels. Keeping a detailed fishing logbook on board is mandatory for most vessels, and large parts of the fleet report to the authorities on a daily basis. There is some evidence that the present catch control and reporting systems are not sufficient to prevent discarding and underreporting of catches, but it has considerably improved in comparison with historical period.

## A. 3 Ecosystem aspects

Considerable effort has been devoted to investigate multispecies interactions in the Northeast Arctic. Some of these investigations have reached the stage where quantitative results are available for use in assessments. Growth of cod depends on availability of prey such as capelin (Mallotus villosus), and variability in cod growth has had major impacts on the cod fishery. Cod are able to compensate only partially for low capelin abundance, by switching to other prey species. This may lead to periods of high cannibalism on young cod, and may result in impacts on other prey species which are greater than those estimated for periods when capelin are abundant. In a situation with low capelin abundance, juvenile herring (Clupea harengus) experience increased predation mortality by cod. The timing of cod spawning migrations is influenced by the presence of spawning herring in the relevant area. The interaction between capelin and herring is illustrated by the recruitment failure of capelin coinciding with years of high abundance of young herring in the Barents Sea. Herring predation on capelin larvae is believed to be partially responsible for the recruitment failure of capelin when young herring are abundant in the Barents Sea.

The composition and distribution of species in the Barents Sea depend considerably on the position of the polar front which separates warm and salty Atlantic waters from colder and fresher waters of arctic origin. Variation in the
recruitment of some species including cod and capelin has been associated with the changes in the influx of Atlantic waters to the large areas of the Barents Sea shelf.

The annual consumption of herring, capelin and cod by marine mammals (mainly harp seals and minke whales) has been estimated to be in the order of 1.5-2.0 million $t$ (Bogstad, Haug and Mehl, 2000; See also Section 1.3.4 AFWG Report 2003).

However, estimates of total annual food consumption of Barents Sea harp seals are in the range of about 3.3-5 million tons (depending on choice of input parameters, ICES 2000d). The applied model used different values for the field metabolic rate of the seals (corresponding to two or three times their predicted basal metabolic rate) and under two scenarios: with an abundant capelin stock and with a very low capelin stock.

1. If capelin was abundant the total harp seal consumption was estimated to be about 3.3 million tons (using lowest field metabolic rate). The estimated consumption of various commercially important species was as follows (in tons): capelin approximately 800,000 , polar cod (Boreogadus saida) 600,000, herring 200,000 and Atlantic cod 100,000.
2. A low capelin stock in the Barents Sea (as it was in 1993-1996) led to switches in seal diet composition, with estimated increased consumption of polar cod ( 870,000 tons), other codfishes (mainly Atlantic cod; 360,000 tons), and herring ( 390,000 tons).

## B. Data

## B. 1 Commercial catch

## Norway

Norwegian commercial catch in tonnes by quarter, area and gear are derived from the sales notes statistics of The Directorate of Fisheries. Data from about 20 sub areas are aggregated on 6 main areas for the gears gill net, long line, hand line, purse seine, Danish seine, bottom trawl, shrimp trawl and trap. For bottom trawl the quarterly area distribution of the catches is adjusted by logbook data from The Directorate of Fisheries and the total bottom trawl catch by quarter and area is adjusted so that the total annual catch for all gears is the same as the official total catch reported to ICES.

No discards are reported or accounted for, but there are several reports of discards. In later years there are also reports of misreporting, saithe is landed as cod in a period with decreasing quotas and availability of cod and good availability of saithe.

The sampling strategy is to have age and length samples from all major gears in each main area and quarter. The main sampling program is sampling the landings. Additional samples from catches are obtained from the coast guard, from observers and from crew members reporting according to an agreed sampling procedure.

There are at present no defined criteria on how to allocate samples to unsampled catches, but the following general procedure has been applied: First look for samples from a neighbouring area if the fishery extends to this area in the same quarter. If there are no samples available in neighbouring areas, search for samples from other gears with the most similar selectivity in the same area or in neighbouring areas. The last option is to search in neighbouring quarters, first from the same gear in the same area, and than from neighbouring areas and similar gears. For some gears, areas and quarters length samples taken by the coast guard are applied and combined with an ALK from a neighbouring area, gear or quarter. ALKs from research surveys (shrimp trawl) are also used to fill holes.

## Russia

Russian commercial catch in tonnes by quarter and area are derived from the All-Russian Institute of fishery and oceanography (Moscow) statistics department. Data from each fishing vessel are aggregated on three ICES subDivision (1, IIa and IIb).Russian fishery by passive gears was almost stopped by the end of the 1940s. At present bottom trawl fishery constitutes more than $95 \%$ cod catch.

The sampling strategy was to conduct mass measurements and collect age samples directly at sea, onboard of both research and commercial vessels to have age and length distributions from each area and quarter. Data on length distribution of cod in catches were collected in areas of cod fishery all the year round by a "standard" fishery trawl (mesh
size is 125 mm in the Russian Economic zone and Svalbard area and 135 mm in the Norwegian Economic zone) and summarized by three ICES sub-areas (1, IIa and IIb). Previously the PINRO area divisions were used, differed from the ICES sub-Divisions.

Age sampling was carried out by two ways: without any selection (otoliths were taken from any fish caught in one trawl, usually from 100-300 sp.) or using a stratified by length sampling method (i.e. approximately $10-15 \mathrm{sp}$. per each $10-\mathrm{cm}$ length group). The last method has been used since 1988.

All fish taken for age-reading were measured and weighted individually.
Catch at age are reported to ICES AFWG by sub-Division (1, IIa and IIb) and quarter (before 1984 - by sub-Division and year). Data on length distribution of cod in catches, as well as age-length keys, are formed for each quarter and area. In the case when a catch is present in the area/quarter but a length frequency is absent, a length frequency for the corresponding quarter, summarised for the whole sea is used. If there is no data on length composition of cod in catches per a quarter within the whole sea, a frequency summarised for the whole year and whole sea is used. Gaps in age-length distributions in subDivisions are filled in with data from the corresponding quarter, summarised for the whole sea. Rest gaps are filled in with information from the age-length key formed for the long-term period (1984-1997) for each quarter and for the whole sea. (Kovalev and Yaragina, 1999). Before 1984 calculation of annually catch cod numbers in sub-Divisions was derived from summarized for both the whole year age-length keys and length distribution in catches.

## Germany and Spain

Catch at age reported to the WG by ICES sub-Division (I, IIa and IIb) and quarter, according to national sampling. Missing quarters/sub-Divisions filled in by use of Russian or Norvegian sampling data.

## Other nations

Total annual catch in tonnes is reported by ICES sub-Divisions. All caches by other nations are taken by trawl. The age composition from the sampled trawl fleets is therefore applied to the catches by other nations.

The text table below shows which country supplied which kind of data for 2000:

|  | Kind of data |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: |
| Country | Caton (catch in weight) | Canum (catch at age in numbers) | Weca (weight at age in the catch) | Matprop (proportion mature by age) | Length composition in catch |
| Norway | x | x | x | x | x |
| Russia | x | x | x | x | x |
| Germany | X | X | X |  | X |
| United Kingdom | x |  |  |  |  |
| France ${ }^{1}$ | x |  |  |  |  |
| Spain | x | x | x |  | x |
| Portugal ${ }^{1}$ | X |  |  |  |  |
| Ireland ${ }^{1}$ | x |  |  |  |  |
| Greenland ${ }^{1}$ | X |  |  |  |  |
| Faroe Islands ${ }^{1}$ | x |  |  |  |  |
| Iceland ${ }^{1}$ | x |  |  |  |  |

${ }^{1}$ As reported to Norwegian and Russian authorities

The nations that sample the catches, provide the catch at age data and mean weights at age on Excel spreadsheet files, and the national catches are combined in Excel spreadsheet files. The data should be found in the national laboratories and with the stock co-ordinator.

For 1983 and later years mean weight at age in the catch is calculated as the weighted average for the sampled catches. For the earlier period (1946-1982) mean weight at age in catches is set equal to mean weight at age in the stock (ICES 2001).

The Excel spreadsheet files used for age distribution, adjustments and aggregations can be found with the stock coordinator and for the current and previous year in the ICES computer system under w:\acfm|afwglyear\personal\name (of stock co-ordinator).

The result files (FAD data) can be found at ICES and with the stock co-ordinator, either in the IFAP system as SAS datasets or as ASCII files on the Lowestoft format, either under w: $\mathbf{a c f m} \backslash \mathbf{a f w g} \backslash \mathbf{2 0 0 0} \backslash$ datalcod_arct or w: $\backslash i f a p d a t a l e x i m p o r t \mid a f w g \backslash c o d \_a r c t . ~$

## B. 2 Biological

For 1983 and later years weight at age in the stock and maturity at age is calculated as weighted averages from Russian and Norwegian surveys during the winter season. Stock weights at age a $\left(\mathrm{W}_{\mathrm{a}}\right)$ at the start of year y are calculated as follows:
$W_{a}=0.5\left(W_{\text {rus }, a-1}+\left(\frac{N_{\text {nbar }, a} W_{\text {nbar }, a}+N_{\text {lof }, a} W_{\text {lof }, a}}{N_{\text {nbar }, a}+N_{\text {lof }, a}}\right)\right)$
where
$W_{r u s, a-1}$ : Weight at age a-1 in the Russian survey in year $\mathrm{y}-1$
$N_{n b a r, a}$ : Abundance at age a in the Norwegian Barents Sea acoustic survey in year y
$W_{n b a r, a}$ : Weight at age a in the Norwegian Barents Sea acoustic survey in year y
$N_{l o f a}$ : Abundance at age a in the Lofoten survey in year y
$W_{\text {lof,a }}$ : Weight at age a in the Lofoten survey in year y

Maturity at age is estimated from the same surveys by the same formulae, replacing weight by proportion mature.
For age groups 12 and older, the stock weights is set equal to the catch weights, since most of this fish is taken during the spawning fisheries, and in most years considerably more fish from these ages are sampled from the catches than from the surveys.

For the earlier period (1946-1982) the maturity at age and weight at age in the stock is based on Russian sampling in late autumn (both from fisheries and from surveys) and Norwegian sampling in the Lofoten spawning fishery. These data were introduced and described in the 2001 assessment report (ICES 2001).

A fixed natural mortality of 0.2 is used both in the assessment and the forecast.
Both the proportion of natural mortality before spawning (Mprop) and the proportion of fishing mortality before spawning (Fprop) are set to 0 . The peak spawning in the Lofoten area occurs most years in late March-early April.

## B. 3 Surveys

Russia

Russian surveys of cod in the southern Barents Sea started in the late 1940s as trawl surveys of young demersal fishes. Since 1957 such surveys have been conducted over the whole feeding area including the Bear Island - Spitbergen area (Baranenkova, 1964; Trambachev, 1981), both young and adult cod have been surveyed simultaneously. In 1984, acoustic methods started to be implemented during surveys of fish stocks (Zaferman, Serebrov, 1984; Lepesevich, Shevelev, 1997; Lepesevich et al., 1999). In 1995 a new acoustic assessment method was applied for the first time, which allowed the differentiation and registration of echo intensities from fish of different length (Shevelev et al., 1998). Methods of calculations of survey indices also changed, e.g. due to the necessity to derive length-based indices for the FLEKSIBEST model (Bogstad et al.1999; Gusev, Yaragina, 2000).

Time of survey conducting has reduced from 5-6 months (September-February) in 1946-1981 to 2-2.5 months (October-December) since 1982. The aim of conducting a survey is to investigate both the commercial size cod as well as the young cod. The survey covers the main areas where fries settle down as well as the commercial fishery takes
place, included cod at age $0+-10+$ years. A total number of more than 400 trawl hauls are conducted during the survey (mainly bottom trawl, a few pelagic trawl).

There are two survey abundance indices at age: 1). absolute numbers (in thousands) computed from the acoustics and 2). trawl indices, calculated as relative numbers per hour trawling.

Ages 3-8 are used in the XSA-tuning.
Joint Russian-Norwegian winter (February) survey
The survey started in 1981 and covers the ice-free part of the Barents see. Both swept area estimates from bottom trawl and acoustic estimates are produced. The swept area estimates are used in the tuning for ages 3-8, and the acoustic estimate are added to the Norwegian acoustic survey in Lofoten and used for tuning for ages 3-11. The survey is described in Jakobsen et al (1997) and Aglen et al. (2002).

## Norwegian Lofoten survey

Acoustic estimates from the Lofoten survey extends back to 1984. The survey is described by Korsbrekke (1997).

## B. 4 Commercial CPUE

## Russia

Two CPUE data series exist, one is historical series, based on RT vessel type (side trawler, 800-1000 HP), which stopped operating in the Barents Sea in the middle of the $1970-\mathrm{s}$, and other one is presently used, based on PST vessel type (stern trawler, 2000 HP ). Information from each fishing trawler was daily transferred to PINRO, including data on each haul (timing, location, gear and catch by species). Yearly catch f cod by the PST trawlers as well as number of hour trawling were summarized and CPUE index (catch on tons per hour fishing) was calculated.

The effort (hours trawling) was scaled to the whole Russian catch. The CPUE indices are split on age groups by age data from the trawl fishery. Data on ages 9-13+ are used in the XSA-tuning.

## C. Estimation of historical stock development

Model used: XSA

Software used: IFAP / Lowestoft VPA suite

Model Options chosen:

Tapered time weighting applied, power $=3$ over 10 years

Catchability independent of stock size for ages $>6$

Catchability independent of age for ages $>=10$

Survivor estimates shrunk towards the mean F of the final 5 years or the 2 oldest ages
S.E. of the mean to which the estimate are shrunk $=1.000$

Minimum standard error for population estimates derived from each fleet $=0.300$

Prior weighting not applied

Input data types and characteristics:

| Type | Name | Year range | Age range | Variable from year to <br> year <br> Yes/No |
| :--- | :--- | :--- | :--- | :--- |
| Caton | Catch in tonnes | 1946 - last data year | $3-13+$ | Yes |
| Canum | Catch at age in <br> numbers | 1946 - last data year | $3-13+$ | Yes |
| Weca | Weight at age in the <br> commercial catch | $1982-$ last data year | $3-13+$ | Yes, set equal to west <br> for 1946-1981 |
| West | Weight at age of the <br> spawning stock at <br> spawning time. | 1946 - last data year | $3-13+$ | Yes |
| Mprop | Proportion of natural <br> mortality before <br> spawning | $1946-$ last data year | $3-13+$ | No - set to 0 for all <br> ages in all years |
| Fprop | Proportion of fishing <br> mortality before <br> spawning | $1960-$ last data year | $3-13+$ | No - set to 0 for all <br> ages in all years |
| Matprop | Proportion mature at <br> age | $1960-$ last data year | $3-13+$ | yes |
| Natmor | Natural mortality | $1960-$ last data year | $3-13+$ | Includes annual est. <br> of cannibalism from <br> 1984, otherwise set <br> to 0.2 for all ages in <br> all years |

Tuning data:

| Type | Name | Year range | Age range |
| :--- | :--- | :--- | :--- |
| Tuning fleet 1 | Russian com. CPUE, <br> trawl | 1985 - last data year | $9-13+$ |
| Tuning fleet 2 | Joint Barents Sea <br> trawl survey, <br> february | 1981- last data year | $3-8$ |
| Tuning fleet 3 | Joint Barents Sea <br> Acoustic, February+ <br> Lofoten Acoustic <br> survey | 1985 - last data year | $3-11$ |
| Tuning fleet 4 | Russian bottom trawl <br> survey, November | 1984 - last data year | $3-8$ |

## XSA-settings

| Type of setting | Settings last year | Used this year (why changed) |
| :---: | :---: | :---: |
| Time series weighting | Tapered time weighting power $=3$ over 10 years | The same |
| Recruitment regression model (catchability analysis) | Catchability dependent of stock size for ages $<6$ <br> Regression type $=\mathrm{C}$ <br> Min. 5 points used <br> Survivor estimates shrunk to the population mean for ages $<6$ <br> Catchability independent of age for ages $>=10$ | The same |
| Terminal population estimation | Survivor estimates shrunk towards the mean F of the final 5 years or the 2 oldest ages. <br> S.E. of the mean to which the estimate are shrunk $=$ 1.0 . <br> Minimum standard error for population estimates derived from each fleet $=$ 0.300 . | The same |
| Prior fleet weighting | Prior weighting not applied | The same |

## D. Short-term projection

Model used: Age structured

Software used: IFAP prediction with management option table and yield per recruit routines

Initial stock size. Taken from the XSA for age 4 and older. The recruitment at age 3 for the initial stock and the following 2 years are estimated from survey data and....(have to decide)

Natural mortality: Set equal to the values estimated for the terminal year.

Maturity: average of the three last years
$F$ and $M$ before spawning: Set to 0 for all ages in all years

Weight at age in the stock: Predicted by applying (10yr average) annual increments by cohort on last years observations.

Weight at age in the catch: Predicted by applying (10yr average) annual increments by cohort on last years observations.

Exploitation pattern: Average of the three last years, scaled by the Fbar (3-6) to the level of the last year
Intermediate year assumptions: F constraint

Stock recruitment model used: None

Procedures used for splitting projected catches: Not relevant

## E. Medium-term projections

Model used: Age structured

Software used: ????

Initial stock size: Same as in the short-term projections.

Natural mortality: Same as in the short-term projections

Maturity: Same as in the short-term projections

F and M before spawning: Same as in the short-term projections

Weight at age in the stock: Same as last year in the short-term projections

Weight at age in the catch: Same as last year in the short-term projections

Exploitation pattern: Same as in the short-term projections

Intermediate year assumptions: Same as in the short-term projections

Stock recruitment model used: ????

Uncertainty models used: @RISK for excel, Latin Hypercubed, 500 iterations, fixed random number generator

1. Initial stock size: Lognormal distribution, LOGNORM(mean, standard deviation), with mean as in the shortterm projections and standard deviation calculated by multiplying the mean by the external standard error from the XSA diagnostics
2. Natural mortality:
3. Maturity:
4. F and M before spawning:
5. Weight at age in the stock:
6. Weight at age in the catch:
7. Exploitation pattern: Average of the three last years, scaled by the Fbar to the level of the last year
8. Intermediate year assumptions: F-constraint
9. Stock recruitment model used: Truncated lognormal distribution, TLOGNORM(mean, standard deviation, minimum, maximum), is used for recruitment age 2, also in the initial year. The long term geometric mean, standard deviation, minimum, maximum are taken from the XSA for the period $1960-4^{\text {th }}$ last year.

## F. Long-term projections

SPR and YPR calculations

## G. Biological reference points

Introduced 1998: Blim=112000t, Bpa=500000t, Flim=0.7, Fpa=0.42
Proposed SGBRP 2003: Blim=220000t, Bpa=460000t, Flim=0.74, Fpa=0.40

## H. Other issues

Since the 1999 AFWG a new assessment model (Fleksibest) has been used to provide alternative assessments and to describe characteristics of the data for this stock.

# Standard Procedure for Assessment XSA/ICA Type 

Stock specific documentation of standard assessment procedures used by ICES.

Stock: North-East Arctic Haddock

Working Group: Arctic Fisheries Working Group
Date: 13-05-04

## A. General

## A. 1 Stock definition

The North-East Arctic Haddock (Melanogrammus aeglefinus) is distributed in the Barents Sea and adjacent waters, mainly in waters above $2^{\circ}$ Celsius. Tagging carried out in 1953-1964 showed the contemporary area of the Northeast Arctic haddock to embrace the continental shelf of the Barents Sea, adjacent waters and polar front. The main spawning grounds are located along the Norwegian coast and area between $70^{\circ} 30^{\prime}$ and $73^{\circ} \mathrm{N}$ along the continental slope. Larvae extruded are widely drifted over the Barents Sea by warm currents. The 0 -group haddock drifts from the spawning grounds eastwards and northwards and during the international 0 -group survey in august it is observed over wide areas in the Barents Sea.Until maturity, haddock are mostly distributed in the southern Barents Sea being their nursery area. Having matured, haddock migrate to the Norwegian Sea.

## A. 2 Fishery

Haddock are harvested throughout a year; in years when the commercial stock is low they are mostly caught as bycatch in cod trawl fishery; when the commercial stock abundance and biomass are high haddock are harvested during their target fishery. On average approximately $25 \%$ of the catch is with conventional gears, mostly longline, which are used almost exclusively by Norway. Part of the longline catches are from a directed fishery.

The fishery is restricted by national quotas. In the Norwegian fishery the quotas are set separately for trawl and other gears. The fishery is also regulated by a minimum landing size, a minimum mesh size in trawls and Danish seine, a maximum by-catch of undersized fish, closure of areas with high density/catches of juveniles and other seasonal and areal restrictions.

In recent years Norway and Russia have accounted for more than $90 \%$ of the landings. Before the introduction of national economic zones in 1977, UK (mainly England) landings made up 10-30\% of the total. Each country fishing for haddock and engaged in the stock assessment provide catch statistic annually. Summary sheets in AFWG Report indicate total yield of haddock by Subareas I, IIa and IIb as well as catch by each country by years. Catch information by fishing gear used by Norway in the haddock fishery is used internally when making estimations at AFWG meeting. Catch quotas were introduced in the trawl fishery in 1978 and for the fisheries with conventional gears in 1989. Since January 1997 sorting grids have been mandatory for the trawl fisheries in most of the Barents Sea and Svalbard area. Discarding is prohibited. The minimum catching size of haddock is 39 cm in the Russian Economic zone, 44 cm in Norwegian Economic zone; both minimum landing sizes are used by respective fleets in the Svalbard area pursuant to the Svalbard Treaty 1920). The fisheries are controlled by inspections at sea, requirement of reporting to catch control points when entering and leaving the EEZs and by inspections when landing the fish for all fishing vessels. Keeping a detailed fishing log-book on board is mandatory for most vessels, and large parts of the fleet report to the authorities on a daily basis. There is some evidence that the present catch control and reporting systems are not sufficient to prevent discarding and under-reporting of catches.

The historical high catch level of $320,000 \mathrm{t}$ in 1973 divides the time-series into two periods. In the first period, highs were close to $200,000 \mathrm{t}$ around 1956, 1961 and 1968, and lows were between 75,000 and $100,000 \mathrm{t}$ in 1959,1964 and 1971. The second period showed a steady decline from the peak in 1973 down to the historically low level of $17,300 \mathrm{t}$ in 1984. Afterwards, landings increased to $151,000 \mathrm{t}$ before declining to $26,000 \mathrm{t}$ in 1990. A new increase peaked in 1996 at 174,000 t . The exploitation rate of haddock has been variable.

The highest fishing mortalities for haddock have occurred at intermediate stock levels and show little relationship with the exploitation rate of cod, in spite of haddock being primarily a by-catch in the cod fishery. The exception is the 1990s when more restrictive quota regulations resulted in a similar pattern in the exploitation rate for both species. It might be expected that good year classes of haddock would attract more directed trawl fishing, but this is not reflected in the fishing mortalities.

## A. 3 Ecosystem aspects

The composition and distribution of species in the Barents Sea depend considerably on the position of the polar front which separates warm and salty Atlantic waters from colder and fresher waters of arctic origin. Variation in the recruitment of haddock has been associated with the changes in the influx of Atlantic waters to the large areas of the Barents Sea shelf.

In dependence on age and season haddock can vary their diet and act as both predator and plankton-eater or benthoseater. During spawning migration of capelin (Mallotus villosus) haddock prey on capelin and their eggs on the spawning grounds. When the capelin abundance is low or when their areas do not overlap, haddock can compensate for lacking capelin with other fish species, i.e. young herring (Clupea harengus) or euphausiids and benthos, which are predominant in the haddock diet throughout a year. Haddock growth rate depends on the population abundance, stock status of main preys and water temperature.

Water temperature at the first and second years of the haddock life cycle is a fairly reliable indicator of year-class strength. If mean annual water temperature in the bottom layer during the first two years of haddock life does not exceed 3.75 C (Kola-section), the probability that strong year-classes will appear is very low even under favourable effect of other factors. Besides, a steep rise or fall of the water temperature shows a marked effect on abundance of year-classes.

Nevertheless, water temperature is not always a decisive factor in the formation of year-class abundance. Strength of year-classes is also determined to a great extent by size and structure of the spawning stock. Under favourable environmental conditions strong year-classes are mainly observed in years when the spawning stock is dominated by individuals from older age groups which abundance is at a fairly high level.

Annual consumption of haddock by marine mammals, mostly seals and whales, depends on stock status of capelin as their main prey. In years when the capelin stock is large the importance of haddock in the diet of marine mammals is minimal, while under the capelin stock reduction a considerable increase in consumption by marine mammals of all the rest abundant Gadoid species including haddock is observed (Korzhev and Dolgov, 1999; Bogstad, 2000).

The appearance of haddock strong year classes usually leads to a substantial increase in natural mortality of juveniles as a result of cod predation.

## B. Data

## B. 1 Commercial catch

## Norway (for Knut's consideration)

Norwegian commercial catch in tonnes by quarter, area and gear are derived from the sales notes statistics of The Directorate of Fisheries. Data from about 20 sub-areas are aggregated on 6 main areas for the gears gill net, long line, hand line, purse seine, Danish seine, bottom trawl, shrimp trawl and trap. For bottom trawl the quarterly area distribution of the catches is adjusted by logbook data from The Directorate of Fisheries and the total bottom trawl catch by quarter and area is adjusted so that the total annual catch for all gears is the same as the official total catch reported to ICES. No discards are reported or accounted for.

The sampling strategy is to have age and length samples from all major gears in each main area and quarter. The main sampling program is sampling the landings. Additional samples from catches are obtained from the coast guard, from observers and from crew members reporting according to an agreed sampling procedure.

There are at present no defined criteria on how to allocate samples to unsampled catches, but the following general procedure has been applied: First look for samples from a neighbouring area if the fishery extends to this area in the same quarter. If there are no samples available in neighbouring areas, search for samples from other gears with the most similar selectivity in the same area or in neighbouring areas. The last option is to search in neighbouring quarters, first from the same gear in the same area, and than from neighbouring areas and similar gears. For some gears, areas and quarters length samples taken by the coast guard are applied and combined with an ALK from a neighbouring area, gear or quarter. ALKs from research surveys (shrimp trawl) are also used to fill holes.

## Russia

Russian commercial catch in tonnes by seasons and area are derived from the All-Russian Institute of fishery and oceanography (Moscow) statistics department. Data from each fishing vessel are aggregated on three ICES subDivision (I, IIa and IIb). Russian fishery by passive gears was almost stopped by the end of the 1940s. Until late 1990's, relative weight (percentage) of haddock taken by bottom trawls in the total Russian yield exceeded 99\%. Only in recent years an upward trend in a proportion of Russian long-line fishery for haddock was observed to be up to $5 \%$ on the average.

The sampling strategy was to conduct mass measurements and collect age samples directly at sea, onboard of both research and commercial vessels to have age and length distributions from each area and season. Data on length distribution of haddock in catches are collected in areas of cod and haddock fishery all the year round by a "standard" fishery trawl (mesh size is 125 mm in the Russian Economic zone and Svalbard area and 135 mm in the Norwegian Economic zone) and summarized by three ICES sub-areas (I, IIa and IIb). Previously the PINRO area divisions were used, differed from the ICES sub-Divisions.

Age sampling was carried out by two ways: without any selection (otoliths were taken from any fish caught in one trawl, usually from $100-300 \mathrm{sp}$.) or using a stratified by length sampling method (i.e. approximately $10-15 \mathrm{sp}$. per each $10-\mathrm{cm}$ length group). The last method has been used since 1988.

All fish taken for age-reading were measured and weighted individually.

Data on length distribution of haddock in catches, as well as age-length keys, are formed for each ICES Subarea, each fishing gear (trawl and longline) and each half year. Catch at age are reported to ICES AFWG by sub-Division (I, IIa and IIb ) for the whole year. In case data on size or age composition of catches by half year are lacking or not representative, aggregated data from corresponding areas for year are used. In the lack of data by ICES Subareas, information on sizeage composition of catches from other areas is used.

## Germany

Catch at age reported to the WG by ICES sub-Division (I, IIa and IIb) according to national sampling. Missing subDivisions filled in by use of Russian or Norwegian sampling data.

## Other nations

Total annual catch in tonnes is reported by ICES sub-Divisions or by Russian and Norwegian authorities directly to WG. All catches by other nations are taken by trawl. The age composition from the sampled trawl fleets is therefore applied to the catches by other nations.

The text table below shows which country supplied which kind of data:

|  | Kind of data |  |  |  |  |
| :--- | :---: | :---: | :---: | :---: | :---: |
| Country | Caton (catch in <br> weight) | Canum (catch at <br> age in numbers) | Weca (weight at <br> age in the catch) | Matprop <br> (proportion <br> mature by age) | Length <br> composition in <br> catch |
| Norway | x | x | x |  | x |
| Russia | x | x | x | x | x |
| Germany | x | x | x |  | x |
| United Kingdom | x |  |  |  |  |
| France | x |  |  |  |  |
| Spain | x |  |  |  |  |
| Portugal | x |  |  |  |  |
| Ireland | x |  |  |  |  |
| Greenland | x |  |  |  |  |
| Faroe Islands | x |  |  |  |  |
| Iceland | x |  |  |  |  |
|  |  |  |  |  |  |

The nations that sample the catches, provide the catch at age data and mean weights at age on Excel spreadsheet files, and the national catches are combined in Excel spreadsheet files. The data should be found in the national laboratories and with the stock co-ordinator.

For 1983 and later years mean weight at age in the catch is calculated as the weighted average for the sampled catches. For the earlier period (1946-1982) mean weight at age in catches is set equal to mean weight at age in the stock.

The Excel spreadsheet files used for age distribution, adjustments and aggregations can be found with the stock coordinator and for the current and previous year in the ICES computer system under w:\acfm\afwglyear\personal\name (of stock co-ordinator).

The result files (FAD data) can be found at ICES and with the stock co-ordinator, either in the IFAP system as SAS datasets or as ASCII files on the Lowestoft format, either under w:\acfm\afwg $\mathbf{2 0 0 0} \backslash$ datalhad_arct or w: \ifapdataleximportlafwg $\backslash$ had_arct.

## B. 2 Biological

For 1983 and later years weight at age in the stock is calculated as weighted averages from Russian (mainly OctoberDecember) and Norwegian (February) surveys during the autumn-winter season. Stock weights at age a $\left(\mathrm{W}_{\mathrm{a}}\right)$ at the start of year y are calculated as follows:

$$
W_{a}=0.5\left(W_{r u s, a-1}+W_{n b a r, a}\right)_{\text {where }}
$$

$W_{r u s, a-1}$ : Weight at age a-1 in the Russian survey in year $\mathrm{y}-1$
$W_{\text {nbar }, a}$ : Weight at age a in the Norwegian Barents Sea survey in year y
Mean weight at age in the stock reflects weight of haddock in the beginning of a year fairly accurately. In case data on weight of individuals from older age groups are lacking or not representative, the fixed long-term mean estimates are used.

For 1989-2001 Norway presented mean weights from the February and Lofoten surveys and for this period the Norwegian weights were from the Lofoten and the Barents Sea (combined).

Because of the deficiency in the observed data from 1984 to 2002, in 2002 for the mentioned period expert estimates of mean weight of older age groups were given which were reduced to values being more in compliance with the haddock growth rate.

Proportion of mature haddock at age is estimated from data presented by Russia for the period 1981-2003 from late autumn - early spring (both from fisheries and from surveys). Russian data on proportion mature in the stock is to a great extent depends on sampling areas and not always reflects true maturity rate for different age groups (WD\# AFWG, 2002). In this relation there is a need to simulate haddock maturity rate by years and age groups or to adjust Russian data to arrive at a more realistic picture. For the earlier period (1946-1980) the maturity at age is set average and based on Russian sampling.

For both estimations and predictions the fixed natural mortality of 0.2 is used, and for age 3-6 mortality from predation is applied in addition.

Both the proportion of natural mortality before spawning (Mprop) and the proportion of fishing mortality before spawning (Fprop) are set to 0 . The peak spawning occurs most years in the middle of April.

## B. 3 Surveys

## Russia

Russian surveys of cod and haddock in the southern Barents Sea started in the late 1940s as trawl surveys of young demersal fishes. Since 1957 such surveys have been conducted over the whole feeding area including the Bear Island Spitbergen area (Baranenkova, 1964; Trambachev, 1981), both young and adult haddock have been surveyed simultaneously. In 1984, acoustic methods started to be implemented during surveys of fish stocks (Zaferman, Serebrov, 1984; Lepesevich, Shevelev, 1997; Lepesevich et al., 1999). In 1995 a new acoustic assessment method was applied for the first time, which allowed the differentiation and registration of echo intensities from fish of different length (Shevelev et al., 1998).

Time of survey conducting has reduced from 5-6 months (September-February) in 1946-1981 to 2-2.5 months (October-December) since 1982. The aim of conducting a survey is to investigate both the commercial size haddock as well as the young haddock. The survey covers the main areas where fries settle down as well as the commercial fishery takes place. A total number of more than 400 trawl hauls are conducted during the survey (mainly bottom trawl, a few pelagic trawl).

There are two survey abundance indices at age: 1). absolute numbers (in thousands) computed from the acoustics and 2). trawl indices, calculated as relative numbers per hour trawling. From 1995 onwards there has been a substantial change in the method for calculating acoustic indices. The acoustic survey is therefore presented in 2 tables (Table B4a and B4b) for old and new method of calculating indices.

Ages 1-7 are used in the XSA-tuning.
Norwegian (from 2000 - Joint Norwegian-Russian) winter (February) survey
The survey started in 1981 and covers the ice-free part of the Barents see. Both swept area estimates from bottom trawl and acoustic estimates are produced. The swept area estimates are used in the tuning for ages $1-8$. The survey is described in Jakobsen et al (1997) and Aglen et al. (2002).

Before 2000 this survey was made without participation from Russian vessels, while in the three latest surveys Russian vessels have covered important parts of the Russian zone. The indices for 1997 and 1998, when the Russian EEZ was not covered, have been adjusted as reported previously (Mehl, 1999). The number of fish (age group by age group) in the Russian EEZ in 1997 and 1998 was interpolated assuming a linear development in the proportion found in the Russian EEZ from 1996 to 1999. These estimates were then added to the numbers of fish found in the Norwegian EEZ and the Svalbard area in 1997 and 1998.

It should be noted that the survey conducted in 1993 and later years covered a larger area compared to previous years (Jakobsen et al. 1997). In 1991 and 1992, the number of young cod (particularly 1- and 2-year old fish) was probably underestimated, as cod of these ages were distributed at the edge of the old survey area. Other changes in the survey methodology through time are described by Jakobsen et al. (1997). Note that the change from 35 to 22 mm mesh size in the codend in 1994 is not corrected for in the time series. This mainly affects the age 1 indices.

## B. 4 Commercial CPUE

## Russia

No Russian data are used in the stock estimations.

## Norway

Historical time series of observations from onboard Norwegian trawlers were earlier used for tuning of older age groups in VPA. The basis was catch per unit effort (CPUE) in Norwegian statistical areas 03, 04 and 05 embracing coastal banks north of the Lofoten, on which approximately $70 \%$ of Norwegian haddock catch fell. However, proportion of haddock taken as by-catch is pretty high and thus it is difficult to estimate their actual catch per unit effort. Since 2002, CPUE indices have not been used in XSA tuning.

## Other data

Not used.

## C Estimation of historical stock development

Model used: XSA

Software used: IFAP / Lowestoft VPA suite

Model Options chosen:

Tapered time weighting applied, power $=3$ over 20 years
Catchability independent of stock size for ages $>6$
Catchability independent of age for ages $>=9$
Survivor estimates shrunk towards the mean F of the final 5 years or the 3 oldest ages
S.E. of the mean to which the estimate are shrunk $=1.000$

Minimum standard error for population estimates derived from each fleet $=0.300$
Prior weighting not applied

Input data types and characteristics:

| Type | Name | Year range | Age range | Variable from year <br> to year <br> Yes/No |
| :--- | :--- | :--- | :--- | :--- |
| Caton | Catch in tonnes | 1950 - last data year | $1-11+$ | Yes |
| Canum | Catch at age in <br> numbers | $1950-$ last data year | $1-11+$ | Yes |
| Weca | Weight at age in the <br> commercial catch | 1983 - last data year | $1-11+$ | Yes, set equal to <br> west for 1950-1982 |
| West | Weight at age of the <br> spawning stock at <br> spawning time. | 1950 - last data year | $1-11+$ | Yes |
| Mprop | Proportion of natural <br> mortality before <br> spawning | $1950-$ last data year | $1-11+$ | No - set to 0 for all <br> ages in all years |
| Fprop | Proportion of fishing <br> mortality before <br> spawning | $1950-$ last data year | $1-11+$ | No - set to 0 for all <br> ages in all years |
| Matprop | Proportion mature at <br> age | $1950-$ last data year | $1-11+$ | Yes, set equal to <br> average for 1950- <br> 1980 |
| Natmor | Natural mortality | $1950-$ last data year | $1-11+$ | Includes annual est. <br> of predation by cod <br> from <br> otherwise set to 0.2 <br> for all ages in all <br> years |

Tuning data:

| Type | Name | Year range | Age range |
| :--- | :--- | :--- | :--- |
| Tuning fleet 1 | Russian bottom trawl <br> survey, October- <br> December | 1983 - last data year | $1-7$ |
| Tuning fleet 2 | Joint Barents Sea <br> trawl survey, <br> February 1982- last data year | $1-8$ |  |
| Tuning fleet 3 | Joint Barents Sea <br> Acoustic survey, <br> February | 1980 - last data year | $1-7$ |

## D Short-term projection

Model used: Age structured

Software used: IFAP prediction with management option table and yield per recruit routines

Initial stock status: is estimated in XSA as abundance of individuals survived in the terminal year for age 3 and older.
Recruitment at age 3 for the start year and the 2 consecutive years is estimated from survey data in RCT3.

Natural mortality is mainly assumed equal to the level estimated for terminal year or to the average for the recent 3 years in dependence on expected cod predation. Method used to determine this parameter and its substantiation are given in the AFWG Reports.

Proportion mature: for current year preliminary actual data presented by Russia are used; for subsequent years - expert estimates by AFWG members. Method used to determine this parameter and its substantiation are given in the AFWG Reports.

F and M prior to spawning are assumed equal to 0 for all ages in all years.

Weight at age in the stock: Method used to determine this parameter and its substantiation are given in the AFWG Reports.

Weight at age in catch: Method used to determine this parameter and its substantiation are given in the AFWG Reports.

Distribution of fishing mortality at age (fishing pattern): For current year it is taken to be at the level of previous year ( $\mathrm{F}_{\text {Status quo }}$ ) or to be equal to average for the recent 3 years; for subsequent years method used to determine this parameter and its substantiation are given in the AFWG Reports.
$F$ and $M$ before spawning: Set to 0 for all ages in all years
Stock recruitment model used: None

Procedures used for splitting projected catches: Not relevant

## E. Medium-term projections

Time lag: 4 years
Software used: Excel with the build-in @RISK to make statistical estimations.

Initial stock status, natural mortality, proportion mature, proportion of F and M prior to spawning, mean weight at age in stock and in catch, exploitation pattern, predicted F in intermediate year: the same as in the short-term prediction.

Stock recruitment model used: ????

Uncertainty models used: @RISK for excel, Latin Hypercubed, 500 iterations, fixed random number generator

1. Initial stock size: Lognormal distribution, LOGNORM (mean, standard deviation), with mean as in the shortterm projections and standard deviation calculated by multiplying the mean by the external standard error from the XSA diagnostics
2. Natural mortality:
3. Maturity:
4. $F$ and $M$ before spawning:
5. Weight at age in the stock:
6. Weight at age in the catch:
7. Exploitation pattern: Average of the three last years, scaled by the Fbar to the level of the last year
8. Intermediate year assumptions: F-constraint
9. Stock recruitment model used: Truncated lognormal distribution, TLOGNORM(mean, standard deviation, minimum, maximum), is used for recruitment age 2, also in the initial year. The long term geometric mean, standard deviation, minimum, maximum are taken from the XSA for the period $1960-4^{\text {th }}$ last year.

## F. Long-term projections

Spawning stock biomass per recruit (SPR) and yield per recruit (YPR) are estimated annually.

## G. Biological reference points

Introduced 1998: Blim=50000t, Bpa=80000t, Flim=0.49, Fpa=0.35

Working Group:... Arctic Fisheries Working Group
Date: 11.05.2004

## A. General

## A.1. Stock definition

The stock of Sebastes marinus (golden redfish) in ICES Sub-areas I and II is found in the northeast Arctic from $62^{\circ} \mathrm{N}$ in the south to north of Spitsbergen. The Barents Sea area is first of all a nursery areas, and relatively few fish are distributed outside Spitsbergen. S. marinus are distributed all over the continental shelf southwards to beyond $62^{\circ} \mathrm{N}$, and also along the coast and in the fjords. The main areas of larval extrusion are outside Vesterålen, on the Halten Bank area and on the banks outside Møre. The peak of larval extrusion takes place ca. one month later than S. mentella, i.e. during beginning of May. Genetic studies have not revealed any hybridisation with $S$. marinus or $S$. viviparus in the area.

## A.2. Fishery

The fishery for Sebastes marinus (golden redfish) is mainly conducted by Norway which accounts for $80-90 \%$ of the total catch. Germany also has a long tradition of a trawl fishery for this species. The fish are caught mainly by trawl and gillnet, and to a lesser extent by longline and handline. The trawl and gillnet fishery have benefited from the females concentrating on the "spawning" grounds during spring. Some of the catches, and most of the catches taken by other countries, are taken in mixed fisheries together with saithe and cod. Important fishing grounds are the Møre area (Svinøy), Halten Bank, the banks outside Lofoten and Vesterålen, and Sleppen outside Finnmark. Traditionally, S. marinus has been the most popular and highest priced redfish species.

Until 1 January 2003 there were no regulations particular for the $S$. marinus fishery, and the regulations aimed at $S$. mentella (see chapter 6.1.1) had only marginal effects on the S. marinus stock. After this date, all directed trawl fishery for redfish (both $S$. marinus and $S$. mentella) is forbidden in the Norwegian Economic Zone north of $62^{\circ} \mathrm{N}$. When fishing for other species it is legal to have up to $20 \%$ redfish (both species together) in round weight as bycatch per haul and on board at any time.

A minimum legal catch size of 32 cm has been set for all fisheries (since 14 April 2004), with the allowance to have up to $10 \%$ undersized (i.e., less than 32 cm ) specimens of S.marinus (in numbers) per haul.

Until 14 April 2004 there were no regulations of the other gears/fleets than trawl fishing for $S$. marinus. After this date, limited moratorium during 1-31 May has been enforced in all fisheries except trawl. When fishing for other species (also during the moratorium) it is allowed to have up to $20 \%$ bycatch of redfish (in round weight) summarized during a week fishery from Monday to Sunday.

After 1 January 2006 it will be forbidden to use gillnets with meshsize less than 120 mm when fishing for redfish.

## A.3. Ecosystem aspects

## B. Data

## B.1. Commercial catch

The landings statistics used by the Arctic Fisheries Working Group (AFWG) are those officially reported to ICES. In cases where such reportings to ICES do not exist, reportings made directly to Norwegian authorities during the fishery have been used as preliminary figures. Norwegian commercial catch in tonnes by quarter, area and gear are derived from the sales notes statistics of The Directorate of Fisheries. Data from about 20 sub areas are aggregated for the gears
gill net, long line, hand line, Danish seine and bottom trawl. For bottom trawl the quarterly area distribution of the catches is area adjusted by logbook data from The Directorate of Fisheries. No discards are reported or accounted for. Reliable estimates of species breakdown (S. mentella vs. S. marinus) by area are available back to 1989. The national landings of redfish for Norway and Russia are split into species by the respective national laboratories. For other countries (and areas) the AFWG has split the landings into $S$. mentella and $S$. marinus based on reports from different fleets to the Norwegian fisheries authorities.

The Norwegian sampling strategy is to have age-length samples from all major gears in each area and quarter. There are at present no defined criteria on how to allocate samples of catch numbers, mean length and mean weight at age to unsampled catches, but the following general process has been applied: First look for samples from a neighbouring area if the fishery extends to this area in the same quarter. If there are no samples available in neighbouring areas, search in neighbouring quarters, first from the same gear in the same area, and than from neighbouring areas and similar gears. The last option is to search for samples from other gears with the most similar selectivity in the same area or in neighbouring areas. For some gears, areas and quarters length samples taken by the coast guard are applied and combined with an ALK from a neighbouring area, gear or quarter. ALKs from research surveys (shrimp trawl) are also used to fill holes.

For Norway, weights at age in the catch are estimated according to the formula which gives the best fit to the lengthweight data pairs collected during the year and applied to the mean length at age.

The text table below shows which country supply which kind of data:

|  | Kind of data |  |  |  |  |  |
| :--- | :--- | :---: | :--- | :--- | :--- | :--- |
| Country | Caton (catch in <br> weight) on <br> unidentified <br> redfish | Caton (catch <br> in weight) on <br> S. marinus | Canum <br> (catch at <br> age in <br> numbers) | Weca <br> (weight at <br> age in the <br> catch) | Matprop <br> (proportion <br> mature by <br> age) | Length <br> composition <br> in catch |
| Norway |  | x | x | x |  | x |
| Russia |  |  |  |  |  |  |
| Germany | x | x |  |  |  |  |
| United Kingdom | x | $\mathrm{x}^{3}$ |  |  |  |  |

${ }^{1)}$ As reported to Norwegian authorities during the fishery (only for the Norwegian Economic Zone and Svalbard)
${ }^{2)}$ For main fishing area until 2001
${ }^{3)}$ Irregularly
The Norwegian and German input files are Excel spreadsheet files, while the Russian input data are supplied on paper and later punched into Excel spreadsheet files before aggregation to international data. The data should be found in the national laboratories and with the stock co-ordinator.

The national data have been aggregated to international data on Excel spreadsheet files. The Russian and German length composition has been applied on the Russian and German landings, respectively, using an age-length-key (ALK) and weight at age data from the Norwegian trawl landings. Catches from the other countries were assumed to have the same age composition and weight at age as the Norwegian trawl landings. In some years the final German and Russian numbers at age have been adjusted to remove SOP discrepancies before aggregation to international data. The Excel spreadsheet files used for age distribution, adjustments and aggregations can be found with the Norwegian stock coordinator and for the current and previous year in the ICES computer system under $\mathbf{w}: \backslash \mathbf{a c f m} \backslash \mathbf{a f w g} \backslash<\mathbf{y e a r}>\backslash$ personal $\backslash$ name (of stock co-ordinator).

The result files (FAD data) can be found at ICES and with the stock co-ordinator, either in the IFAP system as SAS datasets or as ASCII files on the Lowestoft format, either under w: $\backslash \mathbf{a c f m} \backslash \mathbf{a f w g} \backslash$ year $>\backslash$ datalsmr-arct or w: lifapdata $\backslash$ eximport $\backslash$ afwg $\backslash \mathrm{smr}$-arct.

## B.2. Biological

The total catch-at-age data back to 1991 are based on Norwegian otolith readings. In 1989-1990 it was a combination of the German scale readings on the German catches, and Norwegian otolith readings for the rest. In 1984-1989 only German scale readings were available, while in the years prior to 1984 Russian scale readings exist.

Weight at age in the stock is assumed to be the same as weight at age in the catch.

When an analytical assessment is made, a fixed natural mortality of 0.1 is used both in the assessment and the forecast.
Both the proportion of natural mortality before spawning (Mprop) and the proportion of fishing mortality before spawning (Fprop) are set to 0 .

A knife-edge maturity at age 15 has been used for this stock.

## B.3. Surveys

The results from the following research vessel survey series have annually been evaluated by the Working Group:

1) Norwegian Barents Sea bottom trawl survey (February) from 1986-2003 in fishing depths of 100-500 m. Data are available on length for the years 1986-2003, and on age for the years 1992-2003. This survey covers important nursery areas for the stock
2) Norwegian Svalbard (Division IIb) bottom trawl survey (August-September) from 1985-2002 in fishing depths of $100-500 \mathrm{~m}$. This survey covers the northernmost part of the species' distribution.

Data on length and age from both these surveys have been simply added together and used in the assessments.
3) Catch rates (numbers/nautical mile) and acoustic indices of Sebastes marinus from the Norwegian Coastal and Fjord survey in 1995-2002 from Finnmark to Møre. Since 2003, only catch rates are available.

## B.4. Commercial CPUE

The former (until 2002) CPUE-series for S. marinus from Norwegian 32-50 meter freezer trawlers has been improved (e.g., analysing the trawl data with regards to vessel length instead of vessel tonnage) and presented from 1992 onwards. Only data from days with more than $10 \%$ S. marinus in the catches (in weight) were included in the annual averages. The sensitivity/consequences of using different percentages should be further investigated, though the present $20 \%$ bycatch regulation puts limitations on what's possible to use.

Although the trawl fishery until 2003 was almost unregulated, the trawlers experience fewer and fewer fishing days with more than $10 \%$ of their catches composed of $S$. marinus.

## B.5. Other relevant data

None.

## C. Historical Stock Development

The development of the stock has annually been discussed and evaluated based on the research survey series, and information from the fishery.

In some years trial analytical XSA assessments have been made and discussed by the Working Group. In such cases the following settings have been used/recommended, but NOTE that this is subject to further improvement and evaluation before being adopted:

Model used: XSA
Software used: IFAP / Lowestoft VPA suite
Model Options chosen:
Tapered time weighting applied, power $=3$ over 20 years
Catchability independent of stock size for all ages
Catchability independent of age for ages $>=24$
Survivor estimates shrunk towards the mean F of the final 2 years or the 5 oldest ages
S.E. of the mean to which the estimate are shrunk $=2.00$

Minimum standard error for population estimates derived from each fleet $=0.300$
Prior weighting not applied
Input data types and characteristics:

| Type | Name | Year range | Age range | Variable from year <br> to year <br> Yes/No |
| :--- | :--- | :--- | :--- | :--- |
| Caton | Catch in tonnes | 1965 - last data year | $2-24+$ | Yes |
| Canum | Catch at age in <br> numbers | $1965-$ last data year <br> $1)$ | $2-24+$ | Yes |
| Weca | Weight at age in the <br> commercial catch | $1965-$ last data year <br> $1)$ | $2-24+$ | Yes/No - constant at <br> age in begiining of <br> time series |
| West | Weight at age of the <br> stock | $1965-$ last data year <br> $1)$ | $2-24+$ | Yes/No -assumed to <br> be the same as <br> weight at age in the <br> catch |
| Mprop | Proportion of natural <br> mortality <br> spawning | $1965-$ last data year | $2-24+$ | No set to 0 for all <br> ages in all years |
| Fprop | Proportion of fishing <br> mortality before <br> spawning | 1965 - last data year | $2-24+$ | No - set to 0 for all <br> ages in all years |
| Matprop | Proportion mature at <br> age | 1965 - last data year | $2-24+$ | No - knife edged at <br> age 15 |
| Natmor | Natural mortality | 1965 - last data year | $2-24+$ | No -set to 0.1 for all <br> ages in all years |

${ }^{1)}$ Age reading based on only otoliths since 1991 (incl.).
Tuning data:

| Type | Name | Year range | Age range |
| :--- | :--- | :--- | :--- |
| Tuning fleet 1 | Norway bottom <br> trawl, Svalbard, fall | 1992 - last data year | $2-15$ |
| Tuning fleet 2 | Norway bottom <br> trawl, Barents Sea, <br> winter | 1992 - last data year | $3-15$ |
| Tuning fleet 3 | Norway trawl CPUE | 1992 - last data year | $9-23$ |

## D. Short-Term Projection

Model used: Visual inspection/analysis of survey results together with information from the fishery.
No analytical short-term projection has been made for this stock.

## E. Medium-Term Projections

Model used: Visual inspection/analysis of survey results together with information from the fishery.

No analytical short-term projection has been made for this stock.
Uncertainty models used: None

## F. Long-Term Projections

Not done

## G. Biological Reference Points

It is proposed to adopt the average number of the five lowest survey abundance estimates for specimens above 25 cm in the combined February Barents Sea survey and the August Svalbard summer survey during 1986-1997, and Upa as 80\% of the three highest abundance estimates for the same size groups in the same surveys/years. The survey series are at present only available in numbers.

# Stock specific documentation of standard assessment procedures used by ICES. 

Stock: Sebastes Mentella (Deep-Sea Redfish) in Sub-Areas I and II<br>Working Group: Arctic Fisheries Working Group (Afwg)<br>Date:<br>01.05.03

## A. General

## A.1. Stock definition

The stock of Sebastes mentella (deep-sea redfish) in ICES Sub-areas I and II is found in the northeast Arctic from $62^{\circ} \mathrm{N}$ in the south to the Arctic ice north and east of Spitsbergen. The south-western Barents Sea and the Spitsbergen areas are first of all nursery areas. Although some adult fish may be found in smaller subareas, the main behaviour of $S$. mentella is to migrate westwards and south-westwards towards the continental slope as it grows and becomes adult. South of $70^{\circ} \mathrm{N}$ only few specimens less than 28 cm are observed, and south of this latitude $S$. mentella are only found along the slope from about 450 m down to about 650 m depth. The southern limit of its distribution is not well defined but is believed to be somewhere on the slope northwest of Shetland. The stock boundary $62^{\circ} \mathrm{N}$ is therefore more for management purposes than a biological basis for stock separation, although the abundance of this species south of this latitude becomes less. The main areas of larval extrusion are along the slope from north of Shetland to west of Bear Island. The peak of larval extrusion takes place during the first half of April. Genetic studies have not revealed any hybridisation with $S$. marinus or $S$. viviparus in the area.

## A.2. Fishery

The only directed fisheries for Sebastes mentella (deep-sea redfish) are trawl fisheries. By-catches are taken in the cod fishery and as juveniles in the shrimp trawl fisheries. Traditionally, the fishery for S. mentella was conducted by Russia and other East European countries on grounds located south of Bear Island towards Spitsbergen. The highest landings of $S$. mentella were $269,000 \mathrm{t}$ in 1976. This was followed by a rapid decline to $80,000 \mathrm{t}$ in 1980-1981 then a second peak of $115,000 \mathrm{t}$ in 1982. The fishery in the Barents Sea decreased in the mid-1980s to the low level of $10,500 \mathrm{t}$ in 1987. At this time Norwegian trawlers showed interest in fishing S. mentella and started fishing further south, along the continental slope at approximately 500 m depth. These grounds had never been harvested before and were inhabited primarily by mature redfish. After an increase to $49,000 \mathrm{t}$ in 1991 due to this new fishery, landings have been at a level of $10,000-15,000 \mathrm{t}$, except in 1996-1997 when they dropped to $8,000 \mathrm{t}$. Since 1991 the fishery has been dominated by Norway and Russia. Since 1997 ACFM has advised that there should be no directed fishery and that the by-catch should be reduced to the lowest possible level.

The redfish population in Sub-area IV (North Sea) is believed to belong to the North-east Arctic stock. Since this area is outside the traditional areas handled by this Working Group, the catches are not included in the assessment. The landings from Sub-area IV have been $1,000-3,000$ t per year. Historically, these landings have been $S$. marinus, but since the mid1980s trawlers have also caught $S$. mentella in Sub-area IV along the northern slope of the North Sea. Approximately 80\% of the Norwegian catches are considered to be S. mentella.

Strong regulations were enforced in the fishery in 1997. Since then it has been forbidden to fish redfish (both S.marinus and S. mentella) in the Norwegian EEZ north and west of straight lines through the positions:

> 1. N 7000' E $0521^{\prime}$
> 2. N $7000^{\prime}$ E $1730^{\prime}$
> 3. N $7330^{\prime} \mathrm{E} 1800^{\prime}$
> 4. N $7330^{\prime} \mathrm{E} 3556^{\prime}$
and in the Svalbard area (Division IIb). When fishing for other species in these areas, a maximum $25 \%$ by-catch (in weight) of redfish in each trawl haul is allowed.

To provide additional protection of the adult $S$. mentella stock, two areas south of Lofoten have been closed for all trawl fishing since 1 March 2000. The two areas (A and B) are delineated by straight lines between the following positions:

## A

1. N $6630^{\prime} \mathrm{E} 0659^{\prime}$
2. N 6621' E 0644'
3. N 6543 ' E 0600'
4. N $6520^{\prime}$ E $0600^{\prime}$
5. N 6520' E 0530'
6. N 6600' E 0530'
7. N $6630^{\prime} \mathrm{E} 0634.27^{\prime}$

## B

1. N $6236^{\prime} \mathrm{E} 0300^{\prime}$
2. N 6210' E 0115'
3. N $6240^{\prime}$ E $0052^{\prime}$
4. N $6300^{\prime} \mathrm{E} 0300^{\prime}$

Area A has recently been enlarged to include the continental slope north to $\mathrm{N} 67^{\circ} 10^{\prime}$.

Since 1 January 2003 all directed trawl fishery for redfish (both S. marinus and S. mentella) is forbidden in the Norwegian Economic Zone north of $62^{\circ} \mathrm{N}$. When fishing for other species it is legal to have up to $20 \%$ redfish (both species together) in round weight as bycatch per haul and on board at any time.

Since 1 January 2000 a maximum legal by-catch criterion of 10 juvenile redfish (both S.marinus, S. mentella and $S$. viviparus) per 10 kg shrimp has been enforced in the shrimp fishery.

## A.3. Ecosystem aspect

As 0 -group and juvenile this stock is an important plankton eater in the Barents Sea, and when this stock was sound, 0group were observed in great abundance in the upper layers utilizing the plankton production. Especially during the first five-six years of life $S$. mentella is also preyed upon by other species, of which its contribution to the cod diet is well documented.

## B. Data

## B.1. Commercial catch

The landings statistics used by the Arctic Fisheries Working Group (AFWG) are those officially reported to ICES. In cases where such reportings to ICES do not exist, reportings made directly to Norwegian authorities during the fishery have been used as preliminary figures. Norwegian commercial catch in tonnes by quarter, area and gear are derived from the sales notes statistics of The Directorate of Fisheries. Data are aggregated on 17 areas for bottom trawl. For bottom trawl the quarterly area distribution of the catches is area adjusted by logbook data from The Directorate of Fisheries. No discards are reported or accounted for. Reliable estimates of species breakdown (S. mentella vs. S. marinus) by area are available back to 1989. The national landings of redfish for Norway and Russia are split into species by the respective national laboratories. For other countries (and areas) the AFWG has split the landings into $S$. mentella and S. marinus based on reports from different fleets to the Norwegian fisheries authorities.

The Norwegian sampling strategy is to have age-length samples from all major gears in each area and quarter. There are at present no defined criteria on how to allocate samples of catch numbers, mean length and mean weight at age to unsampled catches, but the following general process has been applied: First look for samples from a neighbouring area if the fishery extends to this area in the same quarter. If there are no samples available in neighbouring areas, search in neighbouring quarters, first from the same gear in the same area, and than from neighbouring areas and similar gears. The last option is to search for samples from other gears with the most similar selectivity in the same area or in neighbouring areas. For some gears, areas and quarters length samples taken by the coast guard are applied and combined with an ALK from a neighbouring area, gear or quarter. ALKs from research surveys (shrimp trawl) are also used to fill holes.

For Norway, weights at age in the catch are estimated according to the formula which gives the best fit to the lengthweight data pairs collected during the year and applied to the mean length at age

The text table below shows which country supply which kind of data:

|  | Kind of data |  |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| Country | Caton (catch in weight) on unidentified redfish | Caton (catch in weight) on S. mentella | Canum (catch at age in numbers) | Weca (weight at age in the catch) | Matprop (proportion mature by age) | Length composition in catch |
| Norway |  | X | X | X |  | X |
| Russia |  | x | $\mathrm{x}^{2)}$ | $\mathrm{x}^{2)}$ | x | x |
| Germany | X | $\mathrm{x}^{3}$ |  |  |  | $\mathrm{x}^{3)}$ |
| United Kingdom | x | 1) |  |  |  |  |
| France | x | 1) |  |  |  |  |

| Portugal | x | 1) |  |  |  |  |
| Ireland | x | 1) |  |  |  |  |
| Greenland | x | 1) |  |  |  |  |
| Faroe Islands ${ }^{1)}$ Iceland | x | 1) |  |  |  |  |

${ }^{1)}$ As reported to Norwegian authorities during the fishery (only for the Norwegian Economic Zone and Svalbard)
${ }^{2)}$ For main fishing area until 2001
${ }^{3)}$ Irregularly

The Norwegian and German input files are Excel spreadsheet files, while the Russian input data are supplied on paper and later punched into Excel spreadsheet files before aggregation to international data. The data should be found in the national laboratories and with the stock co-ordinator.

The national data have been aggregated to international data on Excel spreadsheet files. The Russian and German length composition has been applied on the Russian and German landings, respectively, using an age-length-key (ALK) and weight at age data from the Norwegian trawl landings. Catches from the other countries were assumed to have the same age composition and weight at age as the Norwegian trawl landings. In some years the final German and Russian numbers at age have been adjusted to remove SOP discrepancies before aggregation to international data. The Excel spreadsheet files used for age distribution, adjustments and aggregations can be found with the Norwegian stock coordinator and for the current and previous year in the ICES computer system under $\mathbf{w}: \backslash \mathbf{a c f m} \backslash \mathbf{a f w g} \mid<\mathbf{y e a r}>\backslash$ personal $\backslash$ name (of stock co-ordinator).

The result files (FAD data) can be found at ICES and with the stock co-ordinator, either in the IFAP system as SAS datasets or as ASCII files on the Lowestoft format, either under w: $\backslash \mathbf{a c f m} \backslash \mathbf{a f w g} \backslash<\mathbf{y e a r}>\backslash$ data $\mid$ smn_arct or w: $\mathrm{ifapdata} \mid$ eximport $\backslash$ afwg $\mid$ smn_arct.

## B.2. Biological

Since 1991, the catch in numbers at age of $S$. mentella from Russia is based on otolith readings. The Norwegian catch-at-age is based on otoliths back to 1990. Before 1990, when the Norwegian catches of $S$. mentella were smaller, Russian scale-based age-length keys were used to convert the Norwegian length distribution to age.

As input to trial analytical assessments, weight at age in the stock is assumed to be the same as weight at age in the catch.

A fixed natural mortality of 0.1 is used both in the assessment and the forecast.
Both the proportion of natural mortality before spawning (Mprop) and the proportion of fishing mortality before spawning (Fprop) are set to 0 .

Age-based maturity ogives for S. mentella (sexes combined) are available for 1986-1993, 1995 and 1997-2001 from Russian research vessel observations in spring. Average ogives for 1966-1972 and 1975-1983 have been used for the periods 1965-1975 and 1976-1983, respectively. Average ogives for 1975-1983, 1984-1985 and data for 1986-1993 (Table D8) were used to generate a smoothed maturity ogive for 1984-1992 (3 year running average). The 1992-1993 average was used for 1993 and 1994, the 1995 data for 1995, the average for 1995 and 1997 for 1996, and the collected material for the subsequent years up to 2001 were taken as representative for these years.

## B.3. Surveys

The results from the following research vessel survey series have annually been evaluated by the AFWG:

1) The international 0-group survey in the Svalbard and Barents Sea areas in August-September since 1980 (incl.).
2) Russian bottom trawl survey in the Svalbard and Barents Sea areas in October-December since 1978 (incl.) in fishing depths of $100-900 \mathrm{~m}$.
3) Norwegian Svalbard (Division IIb) bottom trawl survey (August-September) since 1986 (incl.) in fishing depths of $100-500 \mathrm{~m}$. Data disaggregated on age only since 1992.
4) Norwegian Barents Sea bottom trawl survey (February) since 1986 (incl.) in fishing depths of 100-500 m. Data disaggregated on age only since 1992.

Although the Norwegian Svalbard (August-September) and Barents Sea (February) groundfish surveys are conducted at different times of the year and may overlap in the south of Bear Island area, the two series can be combined to get an approximate total estimate for the whole area.
5) A new Norwegian survey designed for redfish and Greenland halibut is covering the Norwegian Economic Zone (NEZ) and Svalbard incl. north and east of Spitsbergen in August since 1996 from less than 100 m to 500 m depth. The results from this survey includes survey no. 3) above.
6) Russian acoustic survey in April-May since 1992 (except 1994, 1996 and 2002) on spawning grounds in the western Barents Sea .

The international 0-group fish survey carried out in the Barents Sea in August-September since 1965 does not distinguish between the species of redfish but it is believed to be mostly $S$. mentella. The survey design has improved and the indices earlier than 1980 are not directly comparable with subsequent years. A considerable reduction in the abundance of 0 -group redfish was observed in the 1991 survey: abundance decreased to only $20 \%$ of the 1979-1990 average. With the exception of an abundance index of twice the 1991-level in 1994, the indices have remained very low. Record low levels of less than $20 \%$ of the 1991-1995 average have been observed for the 1996-1999 year classes. The 2000 year class was stronger than the preceding four year classes, whereas the estimate of the 2001 and 2002 year classes are among the lowest on record.

Russian acoustic surveys estimating the commercially sized and mature part of the $S$. mentella stock have been conducted in April-May on the Malangen, Kopytov, and Bear Island Banks since 1986. In 1992 the area covered was extended, and data on age are available for 1992-1993, 1995 and 1997-2001. This is the only survey targeting commercially sized $S$. mentella, but only a limited area of its distribution.

## B.4. Commercial CPUE

Revised catch-per-hour-trawling data for the $S$. mentella fishery have been available from Russian PST- and BMRTtrawlers fishing in ICES Division IIa in March-May 1975-2002, representative for the directed Russian fishery accounting for $60-80 \%$ of the total Russian catch. The Working Group mean that the Russian trawl CPUE series do not represent the trend in stock size but is more a reflection of stock density. This is because the fishery on which these data are based since 1996 was carried out by one or two vessels on localised concentrations in the Kopytov area southwest of Bear Island. This is also reflected by the relative low effort at present. Due to this change in fishing behaviour/effort, CPUEs have been plotted only for the period after 1991.

G. Biological Reference Points
H. Other Issues
I. References

# ANNEX 1 <br> Minutes of the review of the Report of the Artic Fisheries Working Group (ACFM 25-27 May 2004) 

The reviewers compliment the Artic Fisheries Working Group for providing a comprehensive report. All of the terms of references were met, with the exception of the testing of the harvest control rule for haddock. Significant progress have been made with the quality handbook which was attached to the report and which contained a lot of information which was relevant to the ACFM report in the new format. Also significant progress has been made in evaluation of harvest control rules.

The paragraphs in the different stock sections highlighting the specific action taken as a response on last years ACFM technical minutes were appreciated. The chair of the WG presented the assessments and other evaluations done by the WG and highlighted the issues which he considered to be of importance to the review group. He was a great help to the reviewers. The reviewers have a number of general comments and some specific comments to the individual assessments which are given in this report. In addition some points raised at the ACFM meeting are included in this report.

A general comment from the reviewers to the new review process. The review group met three days in advance of ACFM. The first drafts of the report became available only a few days before the review took place. The review group had also to deal with the Report of the North Western Group. In addition one reviewer was not able to come to the meeting. This lead to the situation that only two reviewers had to deal with 2 reports (about 1000 pages) to be read and commented within a week. Also summary sheets for each stock and an overview for each area had to be provided in a new format which took a considerable time. The reviewers felt that the heavy workload and time pressure has negatively affected the quality of the review and recommend that the review procedure is evaluated.

A number of general comments were made on the report in arbitrary order:

1. A lot of standard information (information which does not change from year to year) is given in the quality handbook. It is not considered necessary to duplicate this information in the stock sections of the report since this may lead to inconsistencies. It would be better to update the handbook if this is required.
2. The main body of the report would than consist of the available data, exploitations of the data and the technical assessment including the conclusions from these (the haddock is a good example).
3. The review group advises the group to reconsider the structure of the assessment sections and asks the WG to present the information in a logical order. Although almost all required information was available it was scattered all over the section. The WG should realise that the report is written as a working document to ACFM (reviewers). Preferably the sequence of the information would be structured in such a way that by reading the sections in the presented order, the reviewer can follow the assessment procedure. Also consider the headers of the paragraphs covers the contents and can be used to find information easily. An good example how to structure a section would be the assessment of North Sea herring.
4. Within each stock section a paragraph labelled advice applicable in the last data year and current year is required. (not all users have this information at hand)
5. Also a paragraph labelled management applicable to 2003 and 2004 is required. The information is needed for the ACFM report in the template for the stock advice. Also ACFM must be aware of what kind of management/regulations are presently in place when it formulates its advice
6. The section fisheries becomes redundant when it is in the quality handbook unless the fisheries have changed recently. Describing trends in landings belongs in a different section.
7. Mention routinely whether discard information included in assessment. If it is not mentioned this could be interpreted as forgotten. Mention also whether discarding is thought to be occurring and whether this considered to be is a significant problem.
8. In principle all available information can be presented in tables or figures, even when this is not used for good reasons (to be mentioned). In most cases this has been done. This has been done in most cases
9. The WG is encouraged to use alternative assessment models to explore the data and to illustrate the (un)certainties in the results of the assessment. Many new tools have become available in recent time and are used in various Working Groups.
10. ACFM requires information how the exploitation of the different species is linked though the different fisheries in the area. A descriptions is required defining the different fisheries and comment on the mixed fishery character of the fisheries. Which species are target in these fisheries and which are by catch.

## Norwegian coastal cod

This stock was originally listed as an update assessment but later upgraded as a benchmark. This became not clear from the report. A more extensive evaluation of the data was expected in a benchmark assessment.

Although the assessment is not considered precise, there is not doubt that present recruitment and SSB are very low. The assessment was accepted as a basis for providing advice. The WG is asked to get explore alternative models to explore the available data and investigate how to improve the assessment. This is a stock for which ACFM advises no fishing. So being able to detect any signal of recovery or further deterioration is important. Information on discarding and whether this may be a problem to the assessment should be mentioned. The WG should attempt do bring discard estimates to the meeting. Catches of cod have been split up between NEA cod and Norwegian coastal cod based on the otolith structure. The accuracy of splitting catches between NEA and coastal cod should be discussed.

It was noted that catches (at age 0 decline less in the survey compared to the landings and the mean $q$ values suggest different Z in survey and landings. The input table to RCT is missing. There is a difference in rsquare in XSA tuning fleet for age 2 and the same age in RCT ( .96 and .27 respectively). The reviewers thought they should be the same as it concerns the same data and should be further investigated. The data shown in fig 2.1 show no outlier, suggesting . 96 as the most likely value.

## NEA Haddock

This is a benchmark assessment. The assessment was accepted. The way the assessment was presented is close to the (by the reviewers) desired situation given above in the general comments. The information in the haddock section is restricting to the actual information needed to document the assessment while the auxiliary information was available in the quality handbook. The evaluation of an agreed harvest control rule for haddock was postponed because of lack of time.

More attention should be given to the discussion of the results. For instance there is only line with a reference to a figure with retrospective performance of the assessment. The patterns and possible reasons should be discussed (in a paragraph with a recognisable header).

The arbitrary decision to use a time taper in the XSA assessment was questioned. The usefulness of tapering should have been looked at; certainly in a benchmark procedure. P shrinkage was applied up to age 7. This choice should be justified because it is in general not the recommended option. Also the P-shrinker gets no weight in estimation of survivors.

The assessment has not converged indicating estimated level of fishing mortality is not well defined. One reviewer noted that the discussion on the signals given by the individual fleets the data exploration is less relevant given the dynamics of the stocks. All tuning fleets basically give the same information.

Attention should be given to the comparison of the assessment with those in previous years. ACFM comments on a comparison in its report.

An output table of the predictions (over 3 years) was missing to justify the TAC which would have been set using the agreed harvesting rule. Such a table was provided by the chair and is attached to the minutes.

There may be an error in the SSB on the x -scale in figure 4.7. The SSB value for the final assessment point 'All $\mathrm{SE}=0.50$ ' in the upper right figure does not correspond with the summary table (Fig 4.4). The F-value is OK.

For this stock a management plan has been agreed. A run with a prognoses based on the agreed management plan is missing. On request by the review group the chairman of the WG provided the review group with such a run.

## NEA saithe

This is an update assessment. The assessment was accepted. As a consequence the WG did not deal with all comments in last years minutes and postponed the requested analyses to next year when a full comprehensive assessment is expected to be undertaken. However, the review group thinks that this should not prevent the WG to introduce minor improvements if they do not require extra analyses (the update procedure was primarily introduced to save time).

As last year the reviewers considered the estimated recruitment by RCT is basically the mean and the Acoustic survey does not provide additional information. It would be more transparent to use the GM mean.

The way the corrections was made to calculate the survivors in 2004 for those year classes recruitment estimates were changed manually was questioned. Normally the F values, estimated by XSA, would have been applied to the revised recruitment to calculate the survivors instead of recalculating $F$ at age from the actual catches. To avoid these problems, at least partially, it was suggested that the 1 -group index could be included as a tuning fleet and apply Pshrinkage to this age group. The graphs between index and Stock as diagnostic were considered to be instructive.

Retrospective analyses show large trends of overestimating F and underestimating SSB and inability to predict recruitment. This demonstrates considerable uncertainty on de estimated values of the assessment in the most recent years. It was suggested to try other assessment methods such as ADAPT which will also provide CV's of the estimates of fishing mortality and stock numbers. This should be explored next year, when this stock is assessed as a benchmark. Similar retrospective patterns (underestimating SSB and overestimating F) have been observed in other saithe stocks. There may be several explanation (choice of wrong $M$, immigration) to explain these patterns.

The medium term analyses was not considered reliable as the results are mainly driven by the assumption of mean recruitment and ignoring the bias in the assessment.

## North-East Arctic cod

This is a benchmark assessment since the stock is on the observation list. The assessment was accepted. The review group appreciated that the WG came with estimates of unreported landings and investigated the effect of these on the assessment. However, the validity of the procedure used was questioned. The review group is of the opinion that such evaluation should be carried out within a statistical framework for instance AMCI which can be set up to estimate catches, also for the period 1990-1994. It was noted that Flexibest estimates of catches in this period and later is higher than the reported catch.

If the underreporting only occurred in the years where estimates where available this causes no problems to the assessment. If underreporting also existed in preceding or intermediate years and no estimates are available, this may cause a serious problem to the assessment. It is noted that the assessment indicates a declining trend in F in recent years where the problems with the catch data are known to be existing. The analyses of the individual surveys separately by SURBA come up with same signals with regard to recent trends in F and SSB and support the overall results of the XSA assessment. It is strongly recommended to try alternative assessment models on this stock.

Comparison of tables 3.26 and 3.27 summary with or without cannibalism is confusing because cannibalism was not included in the whole time series presented. The effect of including cannibalism on the presented final results of the assessment is not presented clear. The WG is asked to demonstrate the change to the assessment of including cannibalism s on the estimates of fishing mortality, SSB and recruitment.

Most of the cannibalism mortality takes place before the age of recruitment used in the assessment. It is recognised that survey estimates of age groups younger than the youngest age used in the assessment are affected and would have to be corrected for cannibalism before being used as predictors of recruitment.

The configuration of the XSA assessment includes the use of a power function (P-shrinkage) for ages less than 6 year old. The review group notes that the slopes and $t$-values ect. give no strong argument to include power function in assessment.

Comparison of this years assessment with that of last year show that they are consistent. The differences are well explained by changes in previous years data and corrections for errors.

An output table of the predictions (over 3 years) was missing to justify the TAC which would have been set using the agreed harvesting rule. Such a table was provided by the chair and is attached to the minutes.

It was noted that there was a considerable decline in weight at age in the Norwegian survey for some age groups (eg age group 3). This was not evident in the Russian survey (compare tables A7 and A9)

The results of Flexibest results were compared with those of XSA. There is a difference in the Flexibest SSB estimate and XSA for 2003, but this due to way maturity was modelled. The forecasts were compared as well (long discussion on this). It was noted that the yield forecast from Flexibest is somewhat lower than XSA, particularly so for status quo forecast. However, the difference was lesser for F-values below Fpa. Also, in order to use this model for providing management advice, reference points would need to be recalculated. It would be difficult to extend Flexibest to the time period when survey data are not available. The WG notes that such an extension will require assumptions about the selection pattern of the various fishing fleets backwards in time. The Review Group accepted XSA as the basis for the forecast.

The WG carried out an evaluation of the adopted harvest control rule for cod using a new simulation programme (PROST). The reviewers complimented the Working Group for this exercise. The chair of the WG was complemented for the clear presentation how the evaluation had been done. A lot of progress have been made in how to conduct such an evaluation. It would be helpful for similar exercises in the future that ICES provides a document with guidelines based on the experience from this group.

In the simulation, cyclic processes observed in recruitment, stock size dependent weight at age and maturation were modelled and compared to the observed trends. All observed and assumed relationships have been taken account, including assessment uncertainty but not possible bias is assessment. Although the current assessment shows no retrospective bias presently, it was a big problem in the past it and it may occur in the future again e.g. in periods of large changes in the stock or fishery. It is recommended to test the robustness of the rule with respect to different levels of bias.

It was noted that the present Fpa, in the way it was derived, takes into account the recent bias in the assessments, but bias may increase in the future for unknown reasons as has been observed in many other stocks

In principle the rule is incomplete because it does not specify how the reduction in TAC will be done when the stock falls below Bpa. In practice, while fishing at Fpa the occurrence of this situation in the simulations was less than $1 \%$ so it did not matter. While testing a number of assumed possible actions the rule for these actions would lead to a very low probability of SSB below Bpa in any year. The test runs assume either 1) that the fishing mortality will be reduced proportionally to zero when SSB is between Bpa and Blim or 2) that the TAC is set according to Fpa ignoring the $10 \%$ constraint on flexibility in TAC between successive years. Another assumption would be that the $10 \%$ constraint on the TAC would be maintained if $\mathrm{SSB}<\mathrm{Bpa}$. Such an option would likely be the default option when no agreement on the additional measures can be achieved.

The evaluation should have taken account for implementation error (non compliance with the management rules). Given the existence of underreporting at present, this is important.

It was noted that estimation of future recruitment in the model is different from common practice in the WG. The WG would estimate recruitment based on (survey) indices while the model estimates it from the $\mathrm{S} / \mathrm{R}$ function.

In most predictions a certain percentage of the catch contains of "assumed" recruitment, in other words recruitment estimated from a $S / R$ function or mean. It would be relevant to demonstrate how much of the predicted catch in the 3 year rule is made up by 'assumed' year classes.

It is not clear in Table 3.36 what the last 4 columns represent.
The output presents the results of the last 80 years of a simulation with rule over 100 years having already achieved an increase of the stock comparable with high historical observations. It would have been also interesting to see the results of the years immediate after the implementation of the rule because these would reflect the kind of action which is required by managers in the recent medium term. This information was provided by the chairman of the WG and is attached to the minutes (see Appendix).

The rule has not been tested as a tool to rebuild the stock. Simulations of the rule would have to be done from a poor stock situation in order to do this. The rule is expected to bring the stock in a situation not observed historically and biological responses are extrapolated.

All simulations indicate that the risk of bringing the stock below Blim is very low. This would also have been expected when the PA reference points are chosen correctly. The probability of bringing the stock below Bpa is also low. This implies that the situations where other management decisions have to be taken are rare. In particular the omission of assuming bias in the assessment and implementation error (for instance by implementing an F of $20 \%$ or $40 \%$ higher than intended) should be further investigated before the rule can be considered in accordance with the Precautionary Approach. Also testing the performance of the HCR to rebuild the stock in poor situations should be further investigated.

The rule was also tested with $\mathrm{F}=0.5$ instead of $\mathrm{Fpa}(0.4)$. This leads to high probability of $\mathrm{SSB}<\mathrm{Bpa}(40 \%)$. The analyses support the choice of the value Fpa to be consisted with Bpa. The F $=0.5$ run can be considered as a implementation error or an assessment error of $20 \%$. What really matters is that the stock does not drop below Blim.

## Greenland halibut

This is an update assessment. The precision of the actual estimates of SSB and F by assessment is considered to be low. Nevertheless the assessment was accepted indicative to trends.

The XSA diagnostics are relatively poor and indicate noisy data. They need more considerations because they show high $t$-values and negative slopes, some of them being significant.

In addition to the presented survey graphs, the review group would like to see, if possible, graphs of the results of the three surveys in biomass units.

There seems to be a problem with the catch at age matrix with unexpected high numbers of 10 year olds in almost all years. These numbers originate from Norwegian data (The problem also exists in the survey). It was explained that there were age reading problems with this age group. However, de reviewers cannot understand why this problem would be specific for 10-year-olds in Norwegian catches and not/less for other age groups.

## Sebastes mentella and Sebastes marinus

For both stocks no analytical assessments were attempted. In the technical minutes of last year it was recommended that alternative models should be explored. Without trying to discourage to do such attempts it is considered doubtful whether the results of such models would give a different perception of the situation of these stocks compared to the information present in the report.

It is not considered necessary to consider these stocks every year and updating the tables and figures is sufficient. Presently both stocks are in a very poor situation and this situation is expected to remain for a considerable period irrespective current management actions. Year-classes recruit in the SSB at old age (e.g. 10 years old) and surveys indicate failure of recruitment over a long period.

The WG should attempt to get estimates of bycatch of redfish in the shrimp fisheries.
In addition to the presented survey graphs, the review group would like to see, if possible, graphs of the results of the three surveys in biomass units.

For both species U-type reference points could be developed provided that a sufficient long time series demonstrating a dynamic range is available. Also the reference point would be expressed in biomass units (SSB or fishable stock). The present time series are considered to be too short to do this.

NEA Cod: Results for the first 10 years of the simulation from runs selected by the evaluaters of this stock
Medium-term stochastic simulations to investigate effect of HCR
Time period: 2004-2013
Averages in table given for period 2005-2013
Input: 2004-2006: As in short-term prediction - Table 3.28
2007 and later years: Weight, maturity, fishing mortality and natural mortality as in 2006
Recruitment as described in HCR document
Uncertainty:
Assessment error (uncertainty on number at age in any year):
Normally distributed, cv 0.25
This also applies to recruitment in 2005 and 2006
Also uncertainty in SSB-R relationship, as described in HCR document

Table 3.x Results of medium-term stochastic simulations using the approach presented in WD3.
Averages over the period 2005-2013

[^0]:    ${ }^{1}$ the prey species is included in the relevant 'other' group for this predator.
    ${ }^{2}$ only Parathemisto

[^1]:    ${ }^{1}$ This quotation is taken from point 5.1, in the Protocol of the $31^{\text {th }}$ session of The Joint Norwegian-Russian Fishery Commission and translated to English. For an accurate interpretation, please consult the text in the official languages of the Commission (Norwegian and Russian).

[^2]:    1 Provisional figures, Norwegian catches on Russian quotas are included

[^3]:    1 Provisional figures, Norwegian catches on Russian quotas are included.
    2 USSR prior to 1991.

[^4]:    Input units are thousands and kg - output in tonnes

[^5]:    ${ }^{1}$ Indices adjusted to account for limited area coverage.

[^6]:    ${ }^{1}$ Indices adjusted to account for limited area coverage.

[^7]:    ${ }^{1}$ October-December
    ${ }^{2}$ November-January
    ${ }^{3}$ Adjusted data based on average 1985-1995 distribution
    ${ }^{4}$ Adjusted data based on 2001 distribution
    ${ }^{5}$ Adjusted data 2004

[^8]:    ${ }^{1}$ Lengths adjusted to account for limited area coverage.
    ${ }^{2}$ Limited area coverage.

[^9]:    ${ }^{1}$ Provisional figures.

[^10]:    Input units are thousands and kg - output in tonnes

[^11]:    1 Provisional figures.

[^12]:    2 Provisional figures.

[^13]:    ${ }^{1}$ Provisional figures.
    ${ }^{2}$ Includes former GDR prior to 1991.
    ${ }^{3}$ USSR prior to 1991.
    ${ }^{4}$ UK(E\&W)+UK (Scot.)

[^14]:    ${ }^{1}$ Provisional figures.
    ${ }^{2}$ Split on species according to reports to Norwegian authorities.
    ${ }^{3}$ Split on species according to the 1992 catches.
    ${ }^{4}$ Based on preliminary estimates of species breakdown by area.
    ${ }^{5}$ Includes former GDR prior to 1991.
    ${ }^{6}$ USSR prior to 1991.
    ${ }^{7}$ UK (E\&W) + UK(Scot.)

[^15]:    ${ }^{1}$ Only including days with more than $10 \% S$. marinus in the catches.
    ${ }^{2}$ Provisional figures.

[^16]:    Provisional figures.
    Working Group figures.
    ${ }^{3}$ USSR prior to 1991.

[^17]:    1 Provisional figures.
    ${ }^{2}$ Working Group figures.
    ${ }^{3}$ USSR prior to 1991.

[^18]:    1 Provisional figures.
    ${ }^{2}$ Working Group figure.
    ${ }^{3}$ As reported to Norwegian authorities.
    4 Includes Division Ilb.
    ${ }^{5}$ USSR prior to 1991.

[^19]:    ${ }^{1}$ Side trawlers, 800-1000 hp. From 1983 onwards, side trawlers (SRTM), 1,000 hp. From 1997 based on research fishing.
    2 Stern trawlers, up to 2,000 HP.
    ${ }^{3}$ Arithmetic average of CPUE from USSR RT (or SRTM trawlers) and Norwegian trawlers.
    4 Arithmetic average of CPUE from USSR PST and Norwegian trawlers.
    ${ }^{5}$ For the years 1981-1990, based on average CPUE type B. For 1991-1993, based on the Norwegian CPUE, type A.
    6 Total catch ( t ) of seven years and older fish divided by total effort.
    7 For the years 1988-1989, frost-trawlers 995 BRT (FAO Code 095). For 1990, factory trawlers FVS
    IV, 1943 BRT (FAO Code 090).
    8 Norwegian trawlers, ISSCFV-code 07, 250-499.9 GRT.
    9 Norwegian factory trawlers, ISSCFV-code 09, 1000-1999.9 GRT
    10 From 1992 based on research fishing. 1992-1993: two weeks in May/June and October; 1994-1995: 10 days in May/June
    11 Based on fishery from april-october only, a period with relatively low CPUE. In previous years fishery was carried out throughout the whole year.
    ${ }^{12}$ Based on fishery from october-december only, a period with relatively high CPUE.

[^20]:    ${ }^{1}$ New standard trawl equipment (rockhopper gear and 40 meter sweep length).
    ${ }^{2}$ In millions.

[^21]:    ${ }^{1}$ Adjusted (according to the 1996 distribution) to include the Russian EEZ which was not covered by the survey.

[^22]:    ${ }^{1}$ Provisional figures

[^23]:    ${ }^{1}$ This quotation is taken from point 5.1, in the Protocol of the $31^{\text {th }}$ session of The Joint Norwegian Russian Fishery Commission and translated to English. For an accurate interpretation, please consult the text in the official languages of the Commission (Norwegian and Russian).
