## Report of the

# Herring Assessment Working Group for the Area South of $62^{\circ} \mathrm{N}$ (HAWG) 

## 9-18 March 2004

ICES, Copenhagen

This report is not to be quoted without prior consultation with the General Secretary. The document is a report of an Expert Group under the auspices of the International Council for the Exploration of the Sea and does not necessarily represent the views of the Council.

## EXECUTIVE SUMMARY

The Herring Assessment Working Group (HAWG) met in ICES headquarters from 9 to 18 March 2004. The main terms of reference were to assess the status of and to provide catch options for the North Sea autumn-spawning herring stock in ICES Division IIIa, Sub-area IV and Division VIId, the herring stocks in Division VIa and Subarea VII, the stock of spring-spawning herring in Division IIIa and Subdivisions 22-24 (Western Baltic), and the sprat stocks in Sub-area IV and Divisions IIIa and VIId, e.

The WG reports on the status of all of the stocks ( 8 herring and 3 sprat stocks). Analytical assessments were only carried out on 4 out of the 11 stocks the WG was requested to examine and of these four analytical assessments of only three of the herring stocks were accepted last year. This year the working group adopted the proposed ACFM methodology of allocating assessments to categories (The Benchmark - Update assessment system). Of the different stocks to be considered by the HAWG, the NSAS-stock was on the Observation list, the WBSS was to have a benchmark assessment and herring in VIa, VIIa, Celtic and sprat update assessments. During the progress of the work, the WG agreed to redefine the assessment of WBSS stock into an update assessment as no new relevant information was available and the assessments on Irish Sea herring, herring in VIaS, VIIb and sprat in the North Sea, as experimental assessments. The other stocks were considered as update assessments. For Irish Sea herring, an additional two-stage biomass model was used to assist exploration of the stock dynamics.

The assessments of the autumn spawners in the North Sea, VIaN and the Western Baltic spring spawners (WBSS), are consistent with those presented last year, resulting in little changes in the perception of the stocks. With regard to the model used for the assessment of all herring stocks, namely ICA, concern has been raised about the instability in the selection patterns at older ages which would affect the stock estimates in the early part of the time series. The WG examined the performance of ICA on North Sea herring and Western Baltic Spring Spawners with another regularly used assessment model, XSA. The two models gave very similar perceptions of the state of the stock and the WG felt that the use of the ICA model is still appropriate. This also maintains consistency with assessments in previous years.

Most of the stocks assessed are considered within safe biological limits. Corresponding catch predictions are provided in options tables for 2005, where possible by fleet.

A number of data revisions have been applied to the assessment input data set for North Sea and WBSS at this year's WG, as total catch and catch-at-age have been updated for the catch years 1995-2002. The catch series for West of Scotland (ViaN) herring were extended back to 1957, with no changes in the perception of the status of the stock compared to the 2003-assessment for the years 1976-2002. There is still a need for better input/sampling data for some stocks, and in other stocks there is a lack of fishery independent data. Though few estimates of discards were available, the amount of discards for most fisheries was regarded as insignificant.

The Stock Annexes of the Quality Control Handbook have been drafted and are attached to the HAWG report. In many cases these are incomplete as there is a large amount of information needed for each and they take a considerable amount of time to compile. For stocks without an accepted assessment, general elements (stock definitions, fisheries and ecosystem aspects) are presented.

For VIaN herring, the inclusion of the longer time-series of catches including a period with higher stock productivity and higher biomass, resulted in the WG reviewing the support for the proposed reference points for that stock. The WG considered that the proposed $B_{\lim }$ of $50,000 t$ and a $B_{p a}$ of $75,000 t$ are suitable limits and reference points.

The management arrangement for North Sea herring, adopted in 1998 by EU and Norway, was largely based on medium-term simulations made in 1997. Since this is 7 years ago, and the management regime only became effective recently, the WG found it appropriate to reinvestigate the harvest control rules with new simulations. The simulations and the results are presented in the report.

Two formal requests from the EU-Commission to advise on TACs for herring in the Skagerrak/Kattegat-area, were considered by the HAWG

## Contents

Executive Summary
1 Introduction ..... 1
1.1 Participants. ..... 1
1.2 Terms of Reference ..... 1
1.3 Working Group's response to ad hoc requests ..... 2
1.3.1 Mixed stocks in Division IIIa (Response to letter from the EU-commission). ..... 2
1.3.2 Consequence of transfer of quota from C-fleet to A-fleet (Allowance of $50 \%$ of TAC for herring in Skagerrak and Kattegat to be fished in the North Sea, Special request from the Euorpean Commission) ..... 3
1.4 Reviews of groups or work important for the WG ..... 4
1.4.1 Study Group on the Revision of Data for North Sea Herring (SG REDNOSE) ..... 4
1.4.2 The Planning Group for Herring Surveys [PGHERS] ..... 4
1.4.3 Planning Group on Commercial Catch, Discards and Biological Sampling (PGCCDBS) ..... 5
1.4.4 Methods WG .....  7
1.4.5 EU-Projects: HERGEN and WESTHER ..... 8
1.4.6 New projects on Downs herring ..... 9
1.4.7 Study Group on Herring in the Irish and Celtic Seas (SGHICS) ..... 9
1.5 Commercial catch data collation, sampling, terminology and data requirements ..... 10
1.5.1 Commercial catch and sampling: data collation and handling ..... 10
1.5.2 Sampling ..... 10
1.5.3 Data requirements ..... 11
1.5.4 Terminology ..... 11
1.6 Stock overview ..... 11

### 1.2 Terms of Reference

The Herring Assessment Working Group for the Area South of $\mathbf{6 2}{ }^{\circ} \mathbf{N}$ [HAWG] (Chair: E. Torstensen, Norway) will meet at ICES Headquarters from 9-18 March 2004 to:
a) assess the status of and provide catch options (by fleet where possible) for 2005 for:
i) the North Sea autumn-spawning herring stock in Division IIIa, Subarea IV, and Division VIId (separately, if possible, for Divisions IVc and VIId);
ii) the herring stocks in Division VIa and Subarea VII;
iii) the stock of spring-spawning herring in Division IIIa and Subdivisions 22-24 (Western Baltic);
b) forecasts for North Sea autumn-spawning herring should be provided by fleet for a range of fishing mortalities that have a high probability of rebuilding or maintaining the stock above 1.3 mill tonnes by spawning time in 2004.
c) catch options for Div. IIIa shall be given by fleets taking into account that North Sea herring and Western Baltic herring are taken together in this Division;
d) assess the status of the sprat stocks in Subarea IV and Divisions IIIa and VIId,e;
e) provide specific information on possible deficiencies in the 2004 assessments including, at least, any major inadequacies in the data on catches, effort or discards; any major inadequacies in research vessel surveys data, and any major difficulties in model formulation; including inadequacies in available software. The consequences of these deficiencies for both the assessment of the status of the stocks and the projection should be clarified;
f) comment on this meeting's assessments compared to the last assessment of the same stock, for stocks for which a full or update assessment is presented,
g) document fully the methods to be applied in subsequent update assessments and list factors that would warrant reconsideration of doing an update, and consider doing a benchmark ahead of schedule, for stocks for which benchmark assessments are done.

HAWG will report by 19 March 2004 for the attention of ACFM.

In addition, HAWG was asked to consider the following requests from the EU Commission:

- to advise whether a TAC of 80000 t for herring in the ICES Division IIIa for 2004 is consistent with the precautionary approach
- to advice on consequences of allowing part of the TAC for herring in the Skagerrak and the Kattegat to be fished in the North Sea.

The group has evaluated relevant information and the requests are dealt with in Sections 1.3.1 and 1.3.2, respectively.

### 1.3 Working Group's response to ad hoc requests

### 1.3.1 Mixed stocks in Division IIIa (Response to letter from the EU-commission).

In previous years, the main constraint on the fishery in Division IIIa was the concern for the North Sea autumn spawning herring. This situation has changed since the North Sea autumn spawning herring by now is in a good state. Hence, quotas in Division IIIa, which include both stocks, may have to be constrained by the need to restrict the exploitation of Western Baltic spring spawners (WBSS), which are taken together with North Sea autumn spawners (NSAS) in this area.

The fleets fishing herring in Division IIIa are defined as:
Fleet C: Directed herring fisheries with purse seiners and trawlers
Fleet D: By-catches of herring caught in the small-mesh fisheries
The WBSS are exploited by other fleets as well, in Subdivision 22-24. The advise by ICES on WBSS is on total catches for the stock, covering all areas, but including only WBSS herring in these areas. Hence, to compute the catch of NSAS by fleet corresponding to a given total catch option for WBSS, the first step will be to estimate the amount this will correspond to for the C- and D-fleets. Lacking other information, this is based on the historical share of the total catch by these fleets.

The text table below shows the historical share of the total catch in tonnes of WBSS by fleet.

|  | Fleet C (IIIa) | Fleet D (IIIa) | Subdiv. 22-24 | Total |
| :--- | :--- | :--- | :--- | :--- |
| $\mathbf{2 0 0 1}$ | $33429(34 \%)$ | $3101(3 \%)$ | $61832(63 \%)$ | 98362 |
| $\mathbf{2 0 0 2}$ | $38161(38 \%)$ | $8731(9 \%)$ | $53647(53 \%)$ | 100539 |
| $\mathbf{2 0 0 3}$ | $34382(42 \%)$ | $5287(5 \%)$ | $51931(53 \%)$ | 91601 |
| Average | $38 \%$ | $6 \%$ | $57 \%$ |  |

Next, this share has to be translated to total catch of herring of both stocks (NSAS and WBSS) for each fleet by accounting for the fraction of NSAS in the catches by these fleets. Again, this has to be based on historic experience.

The text table below shows the percent NSAS in the catches by fleet in Division IIIa

|  | Fleet C | Fleet D |
| :---: | :---: | :---: |
| $\mathbf{2 0 0 1}$ | $51 \%$ | $80 \%$ |
| $\mathbf{2 0 0 2}$ | $31 \%$ | $51 \%$ |
| $\mathbf{2 0 0 3}$ | $43 \%$ | $68 \%$ |
| Average | $42 \%$ | $65 \%$ |

From this, it also follows the amount of NSAS by each fleet corresponding to a certain catch option for the total catch of the WBSS stock. The algorithm can be outlined as follows:

1. Start with a total catch of WBSS
2. Allocate this WBSS catch to fleets based on historical shares to get the WBSS catch by the C- and D-fleets.
3. Translate these fleetwise WBSS catches to catches of both stocks together by the C- and D-fleets, using historical data for the fraction of each stock in the C - and D - fleet catches, and further, derive the corresponding catches of NSAS by these fleets.

The text table below gives some examples (values rounded to the nearest 100 tonnes).

| Catch <br> option for <br> WBSS <br> stock | WBSS by C- <br> fleet <br> $(38 \%$ of TAC $)$ | WBSS by D- <br> fleet <br> $(6 \%$ of TAC $)$ | Both stocks <br> by C-fleet <br> $($ WBBS $/ 0.58)$ | Both stocks <br> by D-fleet <br> $($ WBBS $/ 0.35)$ | NSAS by C- <br> fleet <br> $($ Both *0.42) | NSAS by D- <br> fleet (Both <br> $* 0.65)$ |
| :--- | :---: | :---: | :---: | :---: | :---: | :---: |
| 60000 | 22800 | 3600 | 39300 | 10300 | 16500 | 6700 |
| 80000 | 30400 | 4800 | 52400 | 13700 | 22000 | 8900 |
| 96000 | 36500 | 5700 | 62900 | 16500 | 26400 | 10700 |

For a TAC on catch of NSAS and total catch by the fleets in Division IIIa to be compatible with the advise for WBSS, the numbers derived as above, based on with the largest advisable catch of WBSS, are upper bounds on the advisable catches of NSAS by the C- and D- fleets.

For 2004, ICES advised that catches for WBSS should not exceed 92000 tonnes. That translates into a total catch (both stocks) by the C-fleet of 60000 tonnes. Likewise, it translates into a total catch by the D-fleet of 16000 tonnes. ICES was requested to advise whether a TAC of 80000 tonnes for Division IIIa for 2004 would be in accordance with the precautionary approach. This TAC, whether it includes by-catches (D-fleet) or not, would lead to a larger catch of WBSS than the upper bound of the ICES advice for that stock, and therefore is considered not to be in accordance with the precautionary approach.

It may also be noted that a variable, but relatively small amount (up to about 8000 tonnes) of WBSS herring is taken in the fishery in Division IVa. This is accounted for in both the assessments on NSAS and WBSS.

### 1.3.2 Consequence of transfer of quota from C-fleet to A-fleet (Allowance of $50 \%$ of TAC for herring in Skagerrak and Kattegat to be fished in the North Sea, Special request from the Euorpean Commission)

The current fleet definitions are:

## North Sea

Fleet A: Directed herring fisheries with purse seiners and trawlers. By-catches in industrial fisheries by Norway are included.
Fleet B: Herring taken as by-catch under EU regulations.

## Division IIIa

Fleet C: Directed herring fisheries with purse seiners and trawlers
Fleet D: By-catches of herring caught in the small-mesh fisheries
The working group has treated this request as effectively a partial transfer between fleets, but also to some extent a transfer between stocks, since the C-fleet exploits both North Sea autumn spawners (NSAS) and Western Baltic spring spawners (WBSS).

There is no firm basis for predicting the fraction of NSAS in the catches by the C-fleet in future years. It will to some extent depend on the abundance of each stock in the area, which for NSAS is related to the strength of incoming year classes, but also to where and when the fishery is conducted. Hence, the assumption was made that the fraction would be an average over the last 3 years. The text table below shows the percentage of NSAS in the catches in recent years, and the average over the last 3 years.

|  | Fleet C | Fleet D |
| :---: | :---: | :---: |
| $\mathbf{2 0 0 1}$ | $51 \%$ | $80 \%$ |
| $\mathbf{2 0 0 2}$ | $31 \%$ | $51 \%$ |
| $\mathbf{2 0 0 3}$ | $43 \%$ | $68 \%$ |
| Average | $42 \%$ | $65 \%$ |

Thus, one ton of C-fleet total quota can be assumed to represent 0.42 tonnes of catch of NSAS. A transfer of one ton would then imply that the catch of NSAS by the C-fleet is reduced by this amount, while the catch by the A-fleet is increased by one ton.

For 2004 the agreed TAC for the directed fishery in Division IIIa (C-fleet) is 70000 tonnes. of which $50 \%$ can be taken in the North Sea. This implies a transfer of 35000 tonnes from the C-fleet to the A-fleet. Assuming that $42 \%$ of the catch by the C-fleet is NSAS, a transfer of 35000 tonnes leads to a reduction in the outtake of NSAS by the C-fleet of approximately 15000 tonnes, and an increase in the outtake by the A-fleet of 35000 tonnes.

The situation is complicated by misreporting by areas. In recent years, the HAWG in its calculations has assumed that a substantial part of the catch reported as taken in Division IIIa actually has been taken in Subarea IV. These catches have been allocated to the North Sea stock and accounted under the A-fleet. Thus, the very low partial fishing
mortality by the C-fleet represents an estimate, to the best of the Working Groups ability, of the real outtake of NSAS in Division IIIa.

Given this background, there is no obvious way of foreseeing how the agreed transfer will affect current practice. In particular, it is not clear to what extent this will lead to an increase in the real outtake of NSAS in the North Sea, or a real reduction in Division IIIa.

The effect of the transfer on the NSAS stock will be modest in the short-term irrespective of historic fishing practices. Adding 35000 tonnes of catch to the A-fleet (where the $\mathrm{F}_{\mathrm{sq}}$ already accounts for the estimated misreporting from Division IIIa), leads to an increase in F2-6 from 0.24 to 0.26 , resulting in the SSB in 2004 being reduced by about $1 \%$. The effect of the transfer on the exploitation of WBSS will at the most be a reduction of a similar modest magnitude.

### 1.4 Reviews of groups or work important for the WG

### 1.4.1 Study Group on the Revision of Data for North Sea Herring (SG REDNOSE)

SG Rednose met in Copenhagen in January and March 2003 and on correspondence thereafter to verify and correct data used for the North Sea Autumn Spawner assessment (ICES 2003/ACFM:10). The Study group was expected to deliver a reference data set to HAWG by:

- Resolving discrepancies between official databases and data used by the WG, which could not be attributed to misreported/unallocated landings or discards,
- Applying the revised splitting factors for Div. IIIa catch to the assessment input data for 1991-1998,
- Analysing changes of mean weights and numbers-at-age in the catch showing a significant variability, caused by the current procedure for raising national catch data.

Updated national catch and sampling information was obtained for 1995-2001. This was fed into the system used for reallocating samples by the WG since 1999 (see Section 1.5) and a revised reallocation scheme was applied. The majority of discrepancies in historic catch data information were resolved. The revision of national raising schemes reduced the variability in mean weights-at-age as expected. The removal of all Norwegian catch from Div. IIIa, which is now believed to have been taken in the eastern North Sea, required another revision of the split of catches in IIIa. This became apparent only during the SG meeting immediately prior to the 2003 HAWG. The recalculation was conducted after the 2003 WG and the dataset was available for the 2004 HAWG meeting. All relevant report tables and the HAWG archive have subsequently been updated.

The expected transfer of validated historic data into a new ICES database for catch-at-age data collation and handling was not possible, because no such database was operational at the time of the meeting (and still isn't).

### 1.4.2 The Planning Group for Herring Surveys [PGHERS]

The PGHERS met in Flødevigen, Norway, on 27-23 January 2004 under the chair of Bram Couperus. Its terms of reference were to:
a) combine the 2003 survey data to provide indices of abundance for the population within the area;
b) coordinate the timing, area allocation and methodologies for acoustic and larvae surveys for herring and sprat in the North Sea, Division VIa and IIIa and Western Baltic in 2004;
c) review and update the PGHERS manual for acoustic surveys to address standardisation of all sampling tools and survey gears;
d) evaluate the results of the investigations of survey overlaps between vessels in the North Sea acoustic survey;
e) assess the status and future of the HERSUR database;
f) examine digital photographs of herring maturity stages in order to harmonise their definitions.

Larvae surveys. The larvae surveys were still being carried out at the time of the planning group. The results were presented to the Herring Assessment Working Group (HAWG, section 2.3.2). The utility of the surveys was examined by the group and in light of historic and recent studies, the survey was found to be vital to the assessment of North Sea herring. The group also reviewed the use of a larvae index for herring in IIIa and 22-24. This index uses a novel technique of larvae production at 30 mm length as recruitment index. The process study was strong, but the group suggested closer analysis was required prior to incorporation into the assessment. In the 2004/2005 period, the Netherlands and Germany will undertake 7 larvae surveys in the North Sea from 1 September 2004 to 31 January 2005. The Baltic Sea Fisheries Institute will continue with the larvae survey in the Greifswalder Bodden area in 2004.

North Sea acoustic survey. Six acoustic surveys were carried out during late June and July 2003 covering the North Sea and west of Scotland (section 2.3.1). The provisional total combined estimate of North Sea spawning stock biomass (SSB) was 3.1 million t , an increase from 2.9 million t in 2002. The survey showed high numbers of 2-ring and 4-ring herring (the 2000 and 1998 year classes) confirming last year's expectation that the 2000 year class would be strong. The estimate of Western Baltic spring spawning herring SSB was $106,000 \mathrm{t}$, a decrease since $2002(255,000 \mathrm{t})$.

The west of Scotland SSB estimate was $739,000 \mathrm{t}$ (up from $548,000 \mathrm{t}$ ). Six acoustic surveys will be carried out in the North Sea and west of Scotland in 2004 between 28 June and 30 July. Scotia and Tridens will survey an overlapping area to the east of Scotland. Scotia and Johan Hjort will survey an overlapping area to the east of Shetland. Dana, Walther Herwig III and Johan Hjort will survey an overlapping area off north west Denmark. A survey of the western Baltic and southern part of Kattegat, will be carried out by a German research vessel from 29 September to 19 October.

Western Baltic acoustic survey. A joint German-Danish acoustic survey was carried out with R/V Solea from 30 September to 18 October in the Western Baltic. The total number of herring was 5,400 million (down from last years 6,000 million).

Acoustic surveys comparison. A provisional analysis of a spatial overlap of acoustic and trawl catch data was made between FRV Scotia, FRV G.O. Sars and Tridens. Length, age compositions and total abundance estimates were compared. The results for Scotia and Tridens demonstrated agreement, while there were larger differences between Scotia and Sarsen. The group discussed these differences and concluded that differences in timing, sampling strategy and in the interpretation of echograms would be the most likely causes. To solve these problems, it was proposed to conduct both another survey overlap in 2004 (between the Norwegian and two other vessels) and an echogram scrutiny workshop in early 2005.

Methods for acoustic and herring larvae surveys. The manual for herring acoustic surveys in ICES Divisions III, IV, and VIA was reviewed and updated. The new version is 3.2. A completely new manual (version 1.0) has been prepared for the International Herring Larvae Survey. A series of photographs of different herring maturity stages was examined as part of the process to harmonise the herring maturity definitions. It was agreed to make an exchange series of photographs covering the whole spectrum of maturity stages. The status and future of the HERSUR database was discussed. The participants agreed to upload new acoustic data no later than 30 April. During 2004, a meta-database, holding national aggregated data with survey results will be set up by Denmark. This new database will be used to develop further an automated system for delivering output for the combined survey report to the HAWG.

Sprat. Data on sprat were available from RV Walther Herwig III, RV Tridens and RV Dana. The total sprat biomass estimated was $270,000 t$ in the North Sea (up from $241,000 t$ in 2001) and $13,000 t$ in the Kattegat (up from $10,000 \mathrm{t}$ in 2002). The southern summer distribution limit of sprat in the North Sea was still not reached, in spite of the extension of the survey area to $52^{\circ} \mathrm{N}$.

## Recommendations of PGHERS 2004.

PGHERS will meet at the Institute for Marine Research Bergen, Norway, from 24 to 28 January 2005 (chair: B. Couperus, The Netherlands) to:
a) combine the 2004 survey data to provide indices of abundance for the population within the area;
b) co-ordinate the timing, area and effort allocation and methodologies for acoustic and larvae surveys for herring and sprat in the North Sea, Division VIa and IIIa and Western Baltic in 2005;
c) review and update the PGHERS manual for acoustic surveys to address standardization of all sampling tools and survey gears;
d) review the results of an exchange exercise on herring maturity staging, and comment on the implications of the conclusions of the sprat age reading exchange and workshop for the acoustic surveys;
e) evaluate the results of the investigations of survey overlaps between vessels in the North Sea acoustic survey;
f) to conduct an echogram scrutiny workshop aiming at further harmonisation of scrutiny procedures.

### 1.4.3 Planning Group on Commercial Catch, Discards and Biological Sampling (PGCCDBS)

The ICES Planning Group on Commercial Catch, Discards and Biological Sampling [PGCCDBS] met in Palma de Mallorca, 2-5 March to:
a) further regional coordination and co-operation in collecting biological data of landings of fish and shellfish;
b) develop a framework and methodology to ensure spatial / temporal coverage of sampling of biological data from the landings, taking into account the report from the Workshop on sampling and calculation methodology, the report from the Workshop on discard sampling methodology and raising procedures / techniques, the report from the age-reading workshop held in 2003 and from the various otolith exchanges;
c) identify on a regional basis the candidate stocks and species requiring improved ageing;
d) consider data delivered by fisheries' inspectors and how these can be compiled in a consistent way to be used by Assessment Working Groups;
e) compare and standardise protocols for raising national catch and discard data to the international level.

The meeting was attended by 40 participants from 18 countries and representatives from the EU Commission, DG FISH.

ToR a: During the meeting an agreement on establishing regional data collection coordination groups was made.

- Baltic. Originator of the first meeting: Henrik Degel, DIFRES
- North Sea. Originator of the first meeting: Richard Milner, CEFAS
- Western and Southern waters (North east Artic). Originator of the first meeting: Ireland
- Mediterranean. Originator of the first meeting: (not decided yet)

It was also considered whether the North East Artic area should be included in the Western and southern group. No final decision was made concerning this issue.

Some of the tasks of the regional groups are:

- Regional coordination and co-operation in collecting biological data of landings of fish and shellfish
- Report on the main deficiencies in data collection and recommend on how these can be improved.
- Establish bilateral agreements between countries on arrangements of the biological sampling (length and age) of landings by foreign flag vessels.
- Explore the possibilities of (i) task sharing between countries and (ii) setting up joint programmes for the collection of growth, sexual maturity and fecundity data for all analytically assessed fish and shellfish stocks in their region.
- Compare existing manuals for biological sampling to report on inconsistencies and to advice on best practice.

ToR b: Two workshops have been held in the last year. They were the "Discard workshop" and "Workshop on sampling and calculation methodology". The main aim for these workshops was to set up guidelines for data collection concerning discards and port-sampling. The main element can be described as:

- National data collection programmes should be analysed in term of precision of the estimates before going to another step.
- There is no recipe and no simple guideline to estimate the precision for all stocks and all areas.
- Precision should be estimated at a stock level.
- A tool needs to be developed at the international level to produce estimates of precision.

And at the discard workshop it was decided to set up a "Discard Sampling Review Form" and further progress should be:

- The Discard Sampling Review Form should be tested and refined
- The Discard Sampling Review Form should be completed for as many discard sampling programmes as possible
- The information in the Discard Sampling Review Forms should be collated and used to:
- assess current levels of precision of discard estimates
- compare alternative raising procedures, particularly the effect of number of trips and total landings
- identify logistic and methodological problems associated with current sampling strategies
- explore the effect of alternative stratifications, sampling levels, etc on the precision of discard estimates and the corresponding cost of obtaining them
- produce guidelines for sampling and raising that might be generally applicable across a wide range of programmes.

It has been recommended that a workshop devoted exclusively to sampling design should be organised in the beginning of 2005 and the terms of reference should be:
a) analyse the results of precision obtained by each country
b) advise on sampling strategies including stratification and sampling effort

ToR c): It has been agreed that the following otolith exchanges and workshops should be conducted in 2004 and 2005:

2004 Age reading workshops:

- Anglerfish Workshop at IPIMAR, Lisbon, Portugal in November 2004.
- Hake Workshop at IEO, Vigo, Spain in Q4 2004.
- Sprat Workshop at IMR, Flødevigen, Norway September 2004 or January 2005.
- Megrim Workshop at AZTI, Sukarrieta, Spain, date not decided.

2004 and 2005 otolith exchange programmes:

- Roundnose Grenadier (France)
- Sandeel (Denmark)
- Anchovy (Spain)
- Blue whiting (Denmark)
- Saithe (France)
- Turbot and brill (Netherlands)
- Sardine (Portugal)
- Redfishes (Spain)
- Sole (England)
- Horse mackerel (Netherlands)

2005 Age reading workshops:

- Herring Workshop in Finland
- Whiting Workshop in England
- Blue whiting Workshop in Denmark
- Sardine Workshop in Cassablanca

ToR d): The group was informed on the data collection and inspection made by the EU Commission fishing inspectors. Since the recovery plans for cod and southern hake have been implemented in 2004 a more intensive data collection will be carried out. The EU Commission has for the present year planned a random sampling of 100 landings. Inspectors will collect logbook pages from the same vessels fishing with the same gear in the same area and season and will then compare the differences in the landing patterns of inspected and non-inspected trips. These data are not considered relevant to the ICES, HAWG.

ToR e): The current raising procedures used in the different countries were presented at the PGCCDBS meeting and they may be summarized by two different approaches:
a. Directly raising procedure, which means direct raising from sample to estimation in numbers.
b. Raising to total numbers by application of length and age/length keys.

It was agreed that attempts to standardise raising procedures should be made.

## Recommendations for the PGCCDBS in 2005.

PGCCDBS will meet in Belgium or in Greece in the beginning of March 2005 (nominated chair: G. Eltink, The Netherlands) to:
a) review the reports from the Regional Planning Groups and address common issues and propose further actions to be taken;
b) b) propose sampling methodology for fleet/fishery based data collection;
c) review existing information and propose sampling strategies for recreational fisheries;
d) review national descriptions of small scale fleets by country and evaluate the strategies used by different countries to obtain basic information for management purposes;
e) review the report of the WKSCMFD;
f) review the possibilities of using shared ALKs;
g) review the progress of the common regional sampling manuals;
h) review the reports from the age-reading exchanges and workshops and identify on a regional basis the candidate stocks and species requiring improved ageing;

### 1.4.4 Methods WG

The HAWG discussed the draft report of the Methods WG, which met in February 2004. The Methods WG considered 3 main items: Management strategies, performance of several methods on artificial data and generation of artificial data. On management strategies, the HAWG noted the recent development towards harvest control rules, as elements of well tested management strategies, to substitute the current framework of reference points, and recognised that future reference points may be defined primarily as parameters in Harvest Control Rules (HCRs).

Methods WG listed some stocks where development of HCRs could be started already this year, without awaiting further model development to handle e.g. mixed fisheries interactions. This included several stocks covered by the HAWG. In the subsequent meeting of the SGLTA, it was decided to restrict such work to a re-evaluation of the existing HCR for North Sea herring, in order not to increase the work-load of the HAWG.

The other items covered by Methods WG were found useful, in particular, experience with diagnostics, but were not considered to have implications for which tasks the HAWG will have to cover.

### 1.4.5 EU-Projects: HERGEN and WESTHER

HERGEN: Conservation of diversity in an exploited species: spatio-temporal variation in the genetics of herring (Clupea harengus) in the North Sea and adjacent areas. QLRT-2000-01370. (2002-2004).

HERGEN's overall goal is to provide guidelines for the conservation and management of biodiversity of Atlantic herring in the North Sea and adjoining waters by identifying its genetic population structure, and by quantifying relative stock contributions to the fishery. The project incorporates both morphological, otolith and genetic information from 40 sampling sites and has four major scientific objectives:

1. Estimation of genetic differentiation among spawning aggregations. The outcome will enable identification of spatial genetic structure of Atlantic herring in the West of Scotland, North Sea, Kattegat, Skagerrak and Western Baltic. The results obtained are preliminary, but indicate significant genetic substructure, most notably among samples from Subdivision 22-24 and samples from Skagerrak/Kattegat and the North Sea. This corresponds with the possible existence of a hybrid zone in the western Baltic, as is also found in other marine fishes in the same areas (e.g. Turbot: Nielsen et al. (2004) Molecular Ecology, 13, 585-595; Atlantic cod: Nielsen et al. (2003) Molecular Ecology, 12, 1497-1508). Spawning aggregations in the North Sea generally show low levels of genetic differentiation.
2. Determination of temporal stability of population differentiation, based on three types of genetic markers (microsatellites, allozymes, mtDNA). This provides estimates of the temporal variation in genetic structure both on short-term (based on samples from 2002 and 2003) and over 20 years (based on 2002/2003 samples and samples taken in the 1980s). This part of the project is still ongoing.
3. Determination of composition of mixed feeding aggregations using genetic Mixed Stock Analysis. The objective is to quantify the proportions of fish from the various regional spawning components that contribute to mixed aggregations found on common feeding grounds in areas targeted by major fisheries in the North Sea and the Skagerrak/ Kattegat. Microsatellite, allozyme, mtDNA and otolith microstructure data are used separately as well as combined. Preliminary results based on three mixed-stock samples from Skagerrak July 2002 indicate mixing of individuals originating from the three regions North Sea, Skagerrak and Western Baltic (Rügen), with pronounced variation in the contribution of different age components from each of the three regions. Point estimates indicated that 3-ringer fish mainly originated from the Western Baltic (Rügen), 2-ringer fish originated from all three regions, whereas 1-ringer fish mainly originated from the North Sea. The analyses also showed that hatching month estimated from otoliths corresponded well with genetic grouping, such that fish hatched in September and December generally grouped to the North Sea, whereas fish hatched in April grouped to Rügen and to some extent Skagerrak.
4. Determination of temporal (seasonal and annual) variability in contributions to mixed aggregations. The objective is to examine seasonal and annual variation in stock contributions to mixed fisheries by comparing contribution estimates from repeat samples in respectively, the North Sea and Skagerrak/Kattegat. These analyses are ongoing.

Based on the result obtained the most appropriate management units and data collection requirements to monitor selected populations will be explored, taking into account genetic diversity and practical management issues. The information will be disseminated as annual and final reports to the EU, as scientific papers at conferences and in peerreviewed journals and as contributions to ICES annual meetings and working groups (HAWG).

WESTHER: A multidisciplinary approach to the identification of herring (Clupea harengus L.) stock components west of the British Isles using biological tags and genetic markers. Q5RS-2002-01056 (2003-2005).

WESTHER's overall goal is to describe the population structure of herring stocks distributed from the south-west of Ireland and the Celtic Sea to the northwest of Scotland.

To achieve its goal WESTHER has four research objectives: (i) estimation of genetic and phenotypic differentiation between spawning aggregations; (ii) determination of stock origins and life history of juveniles; (iii) determination of composition of feeding aggregations and (iv) improved guidelines for the conservation and management of biodiversity and stock preservation.

The Project started officially on January $1^{\text {st }}, 2003$. Three meetings were organised during the course of the year. There were two plenary meeting, both held in Aberdeen, Scotland, the first in January, the second in December. All partners were present at these meeting. The first meeting was a workshop and co-ordination meeting to provide an organisation plan for the project (specifically the first year), to discuss the structure of the project and to determine working arrangements within and among all partners. At the December meeting progress during the first year, procedures and protocols for revision and the second year's sampling were discussed. The third meeting was between partners 1 and 6 , to standardise techniques for workpackage 03 , parasites as biological tags, and train the new scientists in the techniques.

Two of the major deliverables in the workpackage "Parasites as biological tags" were to produce a list of indicator parasite species that could be used for herring stock discrimination, and to try to isolate genetic markers from selected indicator parasite species to aid in the study of parasites as biological tags. Already in the first year we can report differences in the parasite fauna between herring stocks, indicating their potential for use as biotags in these populations and, in addition, a parasite species new to herring. We also report on the isolation of novel genetic markers from Ani-
sakis and two digenean parasites. The isolation of these new markers will allow a more exhaustive study of these candidate indicator species to be carried out, revealing morphologically cryptic species if present, and allowing differences in populations of the same species to be identified, thus increasing the discriminatory value of these parasites as biotags, beyond the species level.

The genetics work in 2003 concentrated on developing a suite of microsatellite markers that will be used to screen all the samples. Currently we have a panel of 16 candidate markers that will be further developed early in 2004 and used as the standard markers against which all herring will be compared. Our initial aim was to have 12-15 markers. Contamination of the tissue of spawning individuals with eggs and milt seemed to be a problem initially. However, this is no longer deemed to be an issue and screening is proceeding according to plan now.

The second major push to acquire samples is already underway, with two 2004 samples already collected and three more samples due in the first three months. The genetics group will continue to refine their methods to limit contamination problems and will meet, in the second half of 2004, for an inter-calibration meeting.

### 1.4.6 New projects on Downs herring

Members of the Working Group from various Institutes have developed an informal agreement to carry out research into Downs herring. This has been instigated to move the management of the separate quota for Downs herring within the North Sea herring TAC to a more scientific basis. The proposed informal programme takes two main approaches to address the trends in the population; firstly a re-analysis of the larvae surveys of the English Channel and southern North Sea and secondly an investigation of the proportion of winter spawners in the summer catches from the North Sea (the spawning-origin of herring).

The analysis of the larvae surveys is being carried out in the Netherlands and Germany and will apply current methods for determining annually variable larval growth to estimate mortality and hence total larval production. This will hopefully provide a robust estimate of trends in SSB in the English Channel and southern North Sea. The investigation of the spawning-origin of summer catches will use methods developed at DIFRES (in otolith micro-increments) and within HERGEN and apply them to the landings from the feeding aggregations in the North Sea. This should allow the total catch of Downs herring to be estimated. Both these studies are preliminary in nature and will be used in conjunction with the IBTS data on small herring (the $<13 \mathrm{~cm}$ index) and the ongoing and improved MIK series in the southern North Sea (see section 2.11). Discussions between CEFAS and RIVO are already ongoing on the development of management tools that will incorporate these additional data.

It is hoped that within two years, it will be possible to describe an approach to improve the scientific advice on the dynamics of Downs herring and thus underpin with science the advice on the management of the separate quota for Downs herring.

### 1.4.7 Study Group on Herring in the Irish and Celtic Seas (SGHICS)

A small national level study group (participants from Northern Ireland, Republic of Ireland, England \& Wales and the Isle of Man) was convened in Galway (Ireland) on the $15-17^{\text {th }}$ October 2003 to consider aspects of the Irish and Celtic Seas herring stocks. The original terms of reference for this study group were relatively broad, however, it was agreed at the meeting that the group would only consider; 1. Examining the catch-at-age matrix for both stocks and 2 . Work on the Quality Handbook for Irish Sea herring.

In regard to the Irish Sea, the number of samples taken and the methods used to combine catches and estimate the catch-at-age matrix were described and documented in the Quality handbook. The study group also compiled a table stating the location and number of samples used for raising catches and the sources of biological information for the stock for the period 1989 - 2002. Time constraints prevented the group from taking the table back to 1961.

In regard to the Celtic Sea, catch data from the working groups between 1969 and 2003 was reviewed. For each year the catch was recorded so that errors and updates could be tracked and documented. Catch data for this stock was recorded in two series by year (January to December) from 1951 to 2003 and by fishing season (March to February) from 1974 to 2003. For the annual (Jan to December) catch data the source of the final updates are given in text table below:

Catch data for the Celtic Sea and VIIj; sources of information.

| Dates catch data finalised | Year presented | Source of information | Data set |
| :---: | :---: | :---: | :---: |
| 1951-1960 | 1969 WG | Bulletin Statistique | 1951-1960 |
| 1961-1968 | 1973 WG | WG estimates | 1961-1972 |
| 1973-1976 | 1983 WG | WG estimates including VIIj | 1973-1982 |
| 1983-1989 | 1990 WG | WG estimates adjusted upwards by 20\% of Irish catches in VIIg for discards From 1983 to 1989 | 1977-1989 |
| Temporarily adjusted | 1991 WG | WG estimates adjust Irish catches upwards based on roe yield | 1977-1990 |
| 1983-1991 | 1992 WG | WG estimates adjusted back to 1990 WG values but inconsistently rounded | 1977-1991 |
| 1992-2002 | 2003 WG | Most recent WG estimates update to dataset. Catch data after 1997 does not include any discard estimates. Discard estimates from 1990 to 1997 are less than $20 \%$ | 1988-2002 |

An examination of past HAWG Reports and the 2003 WG Report (ICES 2003: ACFM 17) indicated that some of the catch data in the tables are incorrect. The totals in the tables do not precisely agree with the data used in the assessment. This is mostly due to rounding error (the nearest 100 t ) and in other cases typographical errors. The definitive landings data are to be found in the CATON (catch in tonnes) files, currently used for assessment.

### 1.5 Commercial catch data collation, sampling, terminology and data requirements

### 1.5.1 Commercial catch and sampling: data collation and handling

Input spreadsheet and initial data processing. Since 1999 (catch data 1998), the working group members have used a spreadsheet to provide all necessary landing and sampling data. The current version used for reporting the 2003 catch data was v1.6.4. All but one nation provided commercial catch data on these spreadsheets, which were then further processed with the SALLOCL-application (Patterson, 1998b). This program gives the needed standard outputs on sampling status and biological parameters. It also clearly documents any decisions made by the species co-ordinators for filling in missing data and raising the catch information of one nation/quarter/area with information from another data set. This allows recalculation of data in the future (as done by SG REDNOSE, see Section 1.4.1), choosing the same (subjective) decisions made today. Ideally, all data for the various areas should be provided on the standard spreadsheet and processed similarly, resulting in a single output file for all stocks covered by this working group.

More information on data handling transparency, data archiving and the current methods compiling fisheries assessment data are given in the stock annex 2 . To facilitate a long-term data storage, the group stores all relevant catch and sampling data in a separate "archive" folder on the ICES network, which is updated annually. This collection is supposed to be kept confidential as it will contain data on misreporting and unallocated catches, and will be available for WG members on request. This year, North Sea data was updated from 1995 onwards with information gathered by SG Rednose (see Sec. 1.4.1), and VIaN data was added for the period 1957-1975. Table 1.5.1 gives an overview over data available at present, and the source of the data. Members are encouraged to use the latest-version input spreadsheets if it is needed to re-enter catch data. Figure 1.5 .1 shows the separation of areas as used for the long-term storage of data.

Future developments. In this section of the report, the WG has stated since 1999 that the handling of catch data is considered as a priority issue for quality control. The quality of the input data from commercial sampling has proven to be crucial for the quality of the whole assessment procedure. ICES has been asked repeatedly to develop a database application for the proper handling and storage of fisheries catch (-at-age) data. This is also regarded to be a prerequisite for the use of fisheries data for multifleet/multispecies advice. In 2000 ICES indicated that the development of such a database would start in the near future, and HAWG offered support wherever needed.

To facilitate the development, Norway generously provided funding to ICES in 2002, and it was expected that such a database would be operational for all WGs in 2004. The working group last year expressed its satisfaction about this progress. This year, however, it has become apparent that there has been little significant progress. After four years of promises, the WG is more than discontent with the obvious lack of attention that is paid to this issue by ICES. Also, recommendations for the adaptation of assessment software to operating systems currently in use, for interim solutions and to ease access to relevant software and documentation have been constantly ignored. The WG feels that its advice has been as good as useless and its time on these discussions wasted.

If a database application is ever developed, it should be usable by all working groups, and any future format should provide an opportunity to clearly track changes of official landings made by WG members to compensate misreported or unallocated landings or discards. Further, a transparent and effective handling of sampling information obtained from market sampling in foreign ports should be possible. Reference is made here again to a number of documents addressing this issue (e.g. Pastoors, 1999 WD to HAWG; Zimmermann et al. 2000 WD to WGMHSA, EMAS Project report 2001).

### 1.5.2 Sampling

Quality of sampling for the whole area. The working group again produced a map indicating the level of catch sampling by area for all herring stocks covered by HAWG (Figure 1.5.2). The map indicates that the sampling level (in terms of fraction of catch sampled and number of age readings per 1000 t catch) is very different for the various areas. Further details of the sampling quality can be found by stock in the respective sections (Sec. 2.2.4 for North Sea herring, 3.2.6 for Western Baltic Spring Spawners, 4.2.3 for Celtic Sea and VIIj herring, 5.2. for VIa(N) herring, 6.2 .2 for $\mathrm{VIa}(\mathrm{S})$ and VIIb, c herring, 7.2.2 for Irish Sea herring).

Given the diversity of the fleets harvesting most stocks assessed by HAWG, an appropriate spread of sampling effort over the different fisheries/métiers is important to the quality ensure the estimates of catch-at-age data The EU data directive (Commission Regulation 1639/2001) appears not ensure this. The WG therefore recommends that all fisheries/métiers with substantial catch should be sampled (including by-catches in the industrial fisheries) and that catches landed abroad should be sampled and information on these samples should be made available to the national laboratories.

Most of the issues raised her have also been addressed by the Planning Group on Commercial Catch, Discard and Biological Sampling (see Section 1.4.3.).

### 1.5.3 Data requirements

As described in section 1.4.3 the PGCCBDS has agreed to establish regional fisheries data collection coordination and co-operation groups. Furthermore, as the advice on exploitation of the marine fish and shell- fish stocks gradually changes from single-species advice to multi fisheries advice, it is necessary to have data by fishery/metier. As a first step the HAWG has defined the fisheries that exploit the herring stocks which are assessed by the WG. The fishery definition is given in Table 1.5.2.

The regional fisheries data collection coordination and co-operation groups as well as the national laboratories are recommended to take the WG suggestion for fishery definition into account when setting up sampling schemes for 2005.

It should be noticed that this fishery/metier definition is on a lower level of aggregation than prescribed in the EU data directive. In order to be able to give multi fisheries advice it is necessary to harmonize the data directive accordingly.

### 1.5.4 Terminology

The WG noted that the use of "age", "winter rings" and "rings" still causes confusion outside the group (and sometimes even among WG members). The WG tries to avoid this by consequently using "rings" or "ringers" instead of "age" throughout the report. It should be observed that, for autumn spawning stocks, there is a difference of one year between "age" and "rings". Further elaboration on the rationale behind this can be found in the stock annex 2.

### 1.6 Stock overview

In this WG, a total of 8 herring stocks and 3 sprat stocks are considered. Analytical assessments could be carried out for the 4 largest of these 11 stocks. Results of the assessments are presented in the subsequent sections of the report and are summarized below and in Figures 1.6.1-1.6.3.

North Sea autumn spawning herring is the largest stock assessed by this WG. It has experienced very low spawning stock biomass levels in the late 1970s when the fishery was closed for a number of years. In the mid-1990s, the stock again appeared to decrease rapidly after which corrective measures were taken. The stock has expanded again due to the combination of strong recruitments and relatively low fishing mortality on both juvenile and adult herring. Projections indicate a further rise in 2004 followed by a reduction in 2005 due to small incoming year classes. The North Sea Herring stock is well within precautionary limits and harvested sustainably.

Western Baltic Spring Spawners (WBSS) is the only spring spawning stock assessed within this WG. It is distributed in the eastern part of the North Sea, the Skagerrak, the Kattegat and the Subdivisions 22, 23 and 24. In Division IIIa, they mix with North Sea Autumn Spawners. The WBSS herring stock is slowly recovering from the historic low SSB level in 1998. Yield and fishing mortality on the adults are considered to have been reduced in the last years. However, fishing mortality on adults still appears to be high as compared to other herring stocks in European waters.

Celtic Sea herring: The herring fisheries to the south of Ireland in the Celtic Sea and in Division VIIj have been considered to exploit the same stock. For the purpose of stock assessment and management, these areas have been combined since 1982. The fishery in the eastern part of the Celtic Sea was closed in the early eighties due to poor recruitment. Stock assessments have become unstable in the recent past due to fluctuations in recruitment, for which there is no independent measure. F has reduced sharply since 2000; currently SSB cannot be precisely estimated.

West of Scotland herring is one of the medium-sized stocks covered by the WG. It is currently lightly exploited and with two recent good year classes the stock is at a relatively high level compared to last 30 years. Earlier data indicate the possibility of larger stock in the 1960s. The stock experienced a heavy fishery in the mid-70s following closure of the North Sea fishery. The fishery was closed before the stock collapsed. It was opened again along with the North Sea. In the mid 1990s there was substantial area misreporting of catch into this area and sampling of catch deteriorated. Recently the area misreporting has reduced to a very low level and information on catch has improved. Instability in the assessment has reduced considerably and the assessment shows a relatively stable SSB and a low F over the last 3 years.

Herring in VIa south and VIIbc are considered to consist of a mixture of autumn- and winter/spring-spawning fish, which spawn from October to March. The winter/spring-spawning component is distributed in the northern part of the area. The main decline in the overall stock since 1998 appears to have taken place on the autumn-spawning component, and this is particularly evident on the traditional spawning grounds in VIIb. The current levels of SSB and F are not precisely known, as there is no tuned assessment available for this stock. The results of the non-tuned assessment suggest that the SSB may have stabilised at a low level.

Irish Sea autumn spawning herring is one of the smaller stocks assessed by the WG and it comprises two spawning groups (Manx and Mourne). This stock complex experienced a very low biomass level in the late 1970s with an increase in the mid-1980s after the introduction of quotas. The stock then declined from the late 1980s to its present level. During this time period the contribution of the Mourne spawning component has declined and is at present at a very low level. This stock shows annual variability in spawning locations.

North Sea Sprat is the only sprat stock on which an assessment is carried out within this WG. The recruits account for a large proportion of the stock, and the fishery in a given year is very dependent on that year's incoming year class. The size of the stock has been variable with a large biomass in the early 90 's followed by a sharp decline in biomass. The sprat stock now shows signs of being in good condition with an increasing biomass.

The main assessment tools used by this WG is ICA (Patterson, 1998, Needle 2000) which is a separable model over a recent number of years and a conventional VPA over the earlier part of the time-series. This model appears to behave well on the stocks considered by this WG. However, for some stocks additional methods need to be used, e.g. for herring caught in Divisions VIaS and VIIbc where no reliable tuning data are available. For North Sea sprat ageing is considered to be problematic. ACFM in May 2003 has accepted the assessment of North Sea autumn-spawning herring, West of Scotland herring and Baltic spring-spawning herring as full analytical assessments. The other assessments were only considered to be indicative of stock trends.

Biological reference points have been defined for a limited number of stocks. For North Sea autumn-spawning herring, biological reference points are included in a harvest control rule which has been agreed between Norway and the EU. North Sea herring is currently exploited within safe biological limits as the fishing mortality is below $\mathrm{F}_{\mathrm{pa}}$ and the spawning stock above $B_{p a}$.

### 1.7 Biological reference points

Reference points for herring and sprat stocks south of $62^{\circ} \mathrm{N}$ were taken from the ACFM Report, May 2000, and updated by the HAWGR2002. They are summarised in the text table below. The limit reference points for herring West of Scotland (VIa North) was suggested by HAWG 2002.

| STOCK | LIMIT | PRECAUTIONARY |
| :---: | :---: | :---: |
| North Sea autumn spawning herring | $\mathbf{B}_{\lim }$ is 800000 t . <br> Technical basis: Below this value impaired recruitment has been experienced. <br> $\mathbf{F}_{\text {lim }}$ is not defined. | $\mathbf{B}_{\mathrm{pa}}=1.3 \mathrm{mill} \mathrm{t} .$ <br> Technical basis: Part of a harvest control rule based on simulations. <br> $\mathbf{F}_{\mathrm{pa}}$ be set at $\mathrm{F}_{\text {ages 0-1 }}=0.12$; at $\mathrm{F}_{\text {ages 2-6 }}=0.25$. Technical basis: Part of a harvest control rule based on simulations. |
| Western Baltic spring spawning herring | Not specified |  |
| Celtic Sea | $\mathbf{B}_{\text {lim }}$ is 26000 t . <br> Technical basis: The lowest stock observed. $\mathbf{F}_{\text {lim }}$ is not defined | $B_{\mathrm{pa}}$ be set at 44000 t . <br> Technical basis: Reduced probability of low recruitment. |
| West of Scotland | $\begin{aligned} & \mathbf{B}_{\text {lim }} \text { proposed }=50000 \mathrm{t} \\ & \text { Technical basis: } \mathbf{B}_{\text {loss }} \\ & \mathbf{F}_{\text {lim }} \text { is not defined } \\ & \hline \end{aligned}$ | $\begin{aligned} & \mathbf{B}_{\mathrm{pa}} \text { proposed }=75000 \mathrm{t} \\ & \mathbf{F}_{\mathrm{pa}} \text { is not defined } \end{aligned}$ |
| Div. VIaS \& VIIb,c | $\mathbf{B}_{\mathrm{lim}} \text { is } 81000 \mathrm{t} \text {. }$ <br> Technical basis: Lowest reliably estimated SSB. $\mathbf{F}_{\text {lim }} \text { is } 0.33$ | $\mathbf{B}_{\mathrm{pa}}$ be set at 110000 t . <br> Technical basis: Approximately $1.4 \mathbf{B}_{\mathrm{lim}}$. $\mathbf{F}_{\mathrm{pa}}$ be set at 0.22 |
| Irish Sea | $\mathbf{B}_{\text {lim }}$ is 6000 t . <br> Technical basis: Lowest observed SSB. <br> $\mathbf{F}_{\text {lim }}$ is not defined | $\mathbf{B}_{\mathrm{pa}}=9500 \mathrm{t} .$ <br> Technical basis: $\mathbf{B}_{\text {lim }}{ }^{*} 1.58$; still under consideration. <br> $\mathbf{F}_{\mathrm{pa}}$ under review; 0.36 proposed in 1999, not adopted. |
| Sprat North Sea | Not specified | Not specified |
| Sprat in div VIId, e | Not specified | Not specified |
| Sprat in div IIIa | Not specified | Not specified |

### 1.8 Working Documents provided

ICES coordinated acoustic survey of ICES divisions IIIa, IVa, IVb and VIa (North) 2003 results (E. J. Simmonds, C. Zimmermann, E. Götze, S. Jansen, E. Torstensen, B. Lundgren, D. G. Reid, S. Ybema and A. S. Couperus)

Six surveys were carried out during late June and July covering most of the continental shelf north of $52^{\circ} \mathrm{N}$ in the North Sea and to the west of Scotland to a northern limit of $62^{\circ} \mathrm{N}$. The eastern edge of the survey area was bounded by the Norwegian and Danish, Swedish and German coastline and to the west by the shelf edge between 200 and 400 m depth. The combined survey results provide spatial distributions of herring abundance by number and biomass at age by statistical rectangle; and distributions of mean weight and fraction mature at age. The estimates of North Sea autumn spawning herring are consistent with previous years at 3.1 million tonnes and 18,400 million herring. The survey also shows two exceptional year classes of herring (the 1998 and 2000 year classes) in the North Sea, which is consistent with the observation of exceptionally large year classes observed in the MIK and IBTS surveys. The estimates of Western Baltic spring spawning herring SSB are 106,000 tonnes and 823,000 herring and show a substantial decrease compared with the previous year. The West of Scotland survey estimates of 739,000 tonnes and 4,000 million herring shows the high 1995-year class again this year. The 1998-year class (4 ring) is now confirmed being a large one. Indications are found that the 2000- year class is also good. Total adult mortality shows low mortality again (0.1) but the mean mortality over the last 4 years has been around 0.3 . This is consistent with the 2003 assessment that the stock is lightly exploited.

## Report of the herring larvae surveys in the North Sea in 2003/2004 (N. Rohlf \& J. Gröger)

The WD describes spatial and temporal coverage of the larvae surveys and the distribution and abundance of larvae in the areas sampled. Larval Abundance Index (LAI) for separate areas and Multiple Larval Abundance Index (MLAI) for the whole North Sea are shown for the period since 1972. Both the LAI per area as well as the MLAI indicate that the SSB has increase substantially when compared to last years WG estimate.

## Herring Spawning Ground in the Eastern English Channel (C. Mills, P.D. Eastwood \& S.I. Rogers)

The report of ACME 2003/14/1 confirmed that the eastern English Channel is a well known spawning site for the Downs herring stock, and non-spawning herring also feed in the area. It also showed that high densities of herring larvae and substantial herring catches coincided with the area proposed for gravel extraction in ICES rectangle 29F0. There is some concern that removal of gravel, resulting in a sandier seabed, will reduce the quality of the structural habitat for herring spawning, and that such changes are likely to be permanent.

In order to provide more detailed information on individual licence sites, abundance data for herring larvae in the eastern Channel and southern North Sea were reanalysed in GIS, and superimposed on licence boundaries. The attached report describes the methodology used, and shows the extent of overlap between possible aggregate extraction and herring larvae.

## German Herring Fisheries \& Stock assessment data in the Western Baltic in 2003 (T.Gröhsler)

The WD gives a description of the German fishery, fishing fleet, landings (tons) and sampling effort in 2003 for fleets targeting herring in the Baltic Sea. Assessment input data for 2003 is provided as catch in numbers and mean weight in the catch, they are further presented split by fishing fleet, quarter and subdivision.

## Updated Information on Maturity Ogives for Western Baltic Herring (T. Gröhsler \& H. Müller)

The maturity ogives of the Western Baltic herring stock, which is distributed in ICES Division IIIa and Subdivisions 22 -24 , have so far been used as constant over time. A mean maturity-at-age was applied at least since 1991 starting at the age of 1 and reaching $100 \%$ at the age of 5 . The basis for using these values could not be verified by reviewing the recent corresponding working group reports.

The aim of this working document is to provide the HAWG with an accurate set of estimated maturity ogives for recent years, which are based on German bottom trawl survey and commercial fishery in Subdivision 24 in the years 1996 till $2000 \& 2002 \& 2003$. The first results on maturity ogives were already presented as a WD during the 2002 meeting of HAWG.

Relation between the spawning stock biomass of the western Baltic herring (ICES SD 22-24 and DIV. IIIa) and estimates of the larvae surveys in the main spawning area (B. Klenz \& R. Oeberst)

Series of larvae surveys are carried out in the Greifswalder Bodden, the main spawning area of the spring spawning herring in the western Baltic Sea, for estimating the size of the year class of this herring stock, N30, yearly. The relation between N30 and other estimates of the year class was studied by Oeberst and Klenz (2003).

The aim of this study was to estimate the number of hatched larvae using the results of the larvae surveys and to check whether this index is correlated with estimates of the spawning stock. The studies have shown that the indices based on the larvae surveys cannot be used for assessing the spawning stock due to the variable mortality of spawned eggs.

## Herring acoustic Survey in the Celtic Sea and ICES Division VIIj, g \& VIIaS (C. O'Donnell)

The WD describes the 2003 Celtic Sea herring acoustic survey. This was conducted on a commercial vessel using an EK60 echosounder and towed body-mounted transducer. The survey track started at the northern boundary of VIIj and extended to the southeast coast of Ireland in VIIaS. The biomass obtained was considerably higher than in the previous season. The very high proportion of the mature fish observed, and the fact that the traces were inshore puts reasonable confidence in the estimate of abundance obtained. The presence of older fish in the abundance estimate agrees well with the predominance of pre-spawning fish, as it is the older fish that are usually first to migrate inshore to spawn. This may suggest that the younger fish had yet to migrate inshore. Therefore the entire stock may not have been contained in the survey area. The large aggregations observed in Waterford Harbour and near Dunmore East contributed about $50 \%$ to the abundance and biomass estimate. The closure of this area in recent years has obviously been an important factor in replenishing the stock.

## Survey indices of abundance for herring in the Irish Sea (Area VIIaN): 1992-2003 (M. Armstrong, W.Clarke,

 J. Peel, M. McAliskey, W. McCurdy, P. McCorriston, R. Briggs, P-J. Schön, S. Bloomfield, M. Allen and P.Toland)The WD describes results of acoustic, groundfish and larva surveys undertaken in the northern Irish Sea between 1992 and 2003 to provide abundance indices for herring. Updated survey time-series are shown including spawning stock biomass estimate and larval abundance and production estimates. Annual trends in the three surveys are compared. It is concluded that the Irish Sea herring stock remains difficult to survey because of stock mixing problems, as well as aspects of herring behaviour that strongly influence detection and catchability during surveys. Nonetheless, there is evidence for some coherence in the longer-term signals in the different survey series. The trends in spawning stock biomass from the ICES assessment most closely follow the $1+$ biomass estimates from the acoustic survey, including the 2003 survey estimate which was not included in the most recent ICES assessment.

## Assessment of Irish Sea VIIa herring using a Two-Stage Biomass model (B. Roel \& J. de Oliveira)

This WD presents the results of applying a two-stage biomass model to assess the Irish Sea herring stock. The model was fitted to the biomass of 1-ringers and 2+ ringers of the Northern Ireland acoustic survey for the period 1994-2003. The dynamics takes into account only two stages in the population: the recruits (1-ringer fish) and the fully recruited that comprise 2-ringer and older fish. Maximum likelihood estimation is used, assuming survey indices are lognormally distributed about their expected values. Standard errors of the log-distributions are approximated by the sampling CVs. The two-stage biomass model fits the acoustic index generally well with the exception of year 2000 where it suggests the opposite trend. In spite of the high CV associated with the 1999 survey, the poor recruitment estimated by the survey forces a relatively low model estimated $2+$ biomass in 2000 . The results are sensitive to the choice of the $g$ parameter which is fixed externally. A comparison is made between the total biomass estimates from the survey, the two-stage biomass model and ICA (using the acoustic $1+$ index). Both the acoustics index and the two-stage model suggest an increasing trend in the stock biomass starting in 1998. Given the number of "independent" data vs number of estimable parameters the two-stage biomass model is likely to be over-parameterised. A more constrained model (e.g. not allowing the recruitments to vary so freely) could be attempted to address that concern.

## Acoustic surveys of Irish Sea herring (Area VIIaN): do the age structure data contain useful information for ICA tuning? (M. Armstrong \& B. Roel)

Previous Herring Assessment Working Groups have used age-structured abundance indices from an acoustic survey to tune the Irish Sea ICA assessment, but the age compositions are estimated from relatively few midwater trawl hauls only. The object of the present exercise was to see if poor quality age composition data from the acoustic survey could be a contributing factor to annual revisions in the perceived state of the stock.

Comparison of retrospective patterns in estimates of fishing mortality and SSB from ICA shows that using only the aggregate $1+$ biomass index as an SSB tuning series provides more stable assessment results over the 1998-2003 period than are given by the age structured indices. Both survey series will be affected by sampling errors. However the use of age structured data introduces an additional source of error associated with the paucity of representative trawling samples, and in the present case the errors may be sufficiently large to degrade rather than enhance the assessment. A drawback of calibrating ICA estimates of SSB against a $1+$ aggregated survey estimates is that interannual changes in maturity ogives will degrade the calibration. A better solution may be to calibrate an ICA 1+ biomass estimate against the acoustic estimates to maintain comparability through the series but that requires modifying the ICA structure, which is beyond the scope of this study

### 1.9 Recommendations

The HAWG recommends:

### 1.9.1 Data provision and storage

- Due to uncertainties about standardisation of the English trawl catches in 2004 IBTS, these catches are not included in the calculations of 1-5+ ringer indices for $1^{\text {st }}$ Quarter 2004 (North Sea herring). The WG recommends that the IBTS WG evaluates the inclusion of the English 2004 catches in future calculations of IBTS indices. (from section 2.3.3).
- During the HAWG 2002 the Div IIIa IBTS survey data (both quarter) were revised from 1991 to 2002. Historical catch rates are heavily skewed and therefore the survey indices by winter rings 1-5 were calculated as geometric means from observed abundances $\left(\mathrm{n} \cdot \mathrm{h}^{-1}\right)$ at age at trawl stations. However, the 0 -values were omitted and the index is not weighted by rectangle and rectangle area. These indices have been developed by the WG. For HAWG 2005, The WG requests the ICES secretary to provide mean abundances $\left(\mathrm{n} \cdot \mathrm{h}^{-1}\right)$ (CPUE) at age for herring in Div. IIIa from IBTS survey (quarter $1^{\text {st }}$ and $3^{\text {th }}$ ) as an area weighted mean over means by ICES statistical rectangle in accordance to the IBTS WG held in 1999 and as usually
applied for other stocks in the area (ICES 1999/D:2).The contribution of autumn spawned 2-5+ ringers in Division IIIa should be evaluated in the calculation of (from section 3.3.1.).
- If data on sprat from the IBTS survey during the third quarter were available prior to W.G. in 2005 a comparison between the February and the third quarter IBTS indices could be performed with the aim of obtaining an index of abundance of age 1 sprat. Further examination on maturity at length and at age, available from the IBTS conducted in the $3^{\text {rd }}$ quarter and commercial catches could provide important insight into the maturity dynamics during the autumn resulting in a better understanding of the spawning and recruitment processes. Therefore, the WG recommends that countries involved in IBTS analyze data on ma-turity-at-age of sprat and make available the results prior to the 2005 WG meeting. (from section 8 )
- The WG recommends that all fisheries/métiers with substantial catch should be sampled (including bycatches in the industrial fisheries) and that catches landed abroad should be sampled and information on these samples should be made available to the national laboratories. (from section 2.2.4).

### 1.9.2 <br> Surveys

- The North Sea herring larvae surveys should be considered for priority 1 EU funding, as it is international, covers more than 1 species (herring larvae, cod and plaice eggs) and is incorporated into the stock assessment. Efforts should be made to cover the Orkney/Shetland, Buchan and central North Sea area also in the first half of September (from section 2.3.2.)
- In order to avoid bias due to catch-ability differences between gears used in the IBTS-MIK sampling, the WG recommends a full standardisation of the sampling programme, hence, that Scotland changes gear to the 2 -metre ring version with standard netting. (from section 2.3.3.)

### 1.9.3 Assessment methods

- The WG recommends that the Working Group of Methods again considers assessment methods of shortlived species in the light of recent developments (from section 8.8)

### 1.9.4 Planning Groups

- PGHERS will meet at the Institute for Marine Research Bergen, Norway, from 24 to 28 January 2005 (chair: B. Couperus, The Netherlands) to:
a) combine the 2004 survey data to provide indices of abundance for the population within the area;
b) co-ordinate the timing, area and effort allocation and methodologies for acoustic and larvae surveys for herring and sprat in the North Sea, Division VIa and IIIa and Western Baltic in 2005;
c) review and update the PGHERS manual for acoustic surveys to address standardization of all sampling tools and survey gears;
d) review the results of an exchange exercise on herring maturity staging, and comment on the implications of the conclusions of the sprat age reading exchange and workshop for the acoustic surveys;
e) evaluate the results of the investigations of survey overlaps between vessels in the North Sea acoustic survey;
f) to conduct an echogram scrutiny workshop aiming at further harmonisation of scrutiny procedures.

Fishery definitions for herring landings to be used for sampling schemes.

Figure 1.5.1 ICES AREAS as used for the assessment of herring stocks south of $62^{\circ} \mathrm{N}$. Area names in italics indicate the separation used for long-term storage of commercial catch and sampling data. "Transfer area" refers to the transfer of Western Baltic Spring Spawners caught in the North Sea to the Baltic Assessment.

Figure 1.5.2 Herring south of $62^{\circ} \mathrm{N}$ : Sampling level per ICES areas for the whole year and all fleets. Circle diameter is proportional to working group catch; share of sampled catch (black) is indicated. Numbers give the numbers of age readings per 1000 t catch. For the allocation of areas to stocks, see Fig. 1.5.1.

Figure 1.6.1 WG estimates of yield of the stocks presented in HAWG 2004.

Figure 1.6.2 Spawning stock biomass estimates of the 4 stocks for which analytical assessments were presented in HAWG 2004. The $\mathbf{B}_{\mathrm{pa}}$ level (if available) is indicated in the graphs.

Figure 1.6.3 Estimates of mean $F$ of the 4 stocks for which analytical assessments were presented in HAWG 2004. The $\mathbf{F}_{\mathrm{pa}}$ level (if available) is indicated in the graphs.

### 2.1 The Fishery

### 2.1.1 ACFM advice and management applicable to 2003 and 2004

According to the management scheme agreed between the EU and Norway, adopted in December 1997, efforts should be made to maintain the SSB of North Sea Autumn Spawning herring above the MBAL (Minimum Biologically Acceptable Level) of 800,000 tonnes. An SSB reference point of 1.3 million has been set $\left(=\mathbf{B}_{\mathrm{pa}}\right)$ above which the TACs will be based on an $\mathrm{F}=0.25$ for adult herring and $\mathrm{F}=0.12$ for juveniles. If the SSB falls below 1.3 million tonnes, other measures will be agreed and implemented taking account of scientific advice.

Since 2002, the SSB is considered to have been above $\mathbf{B}_{\mathrm{p} \text {. }}$. From then on, ACFM gave fleetwise catch option tables for fishing mortalities within the constraints the EU-Norway management scheme. The advice for a sub-TAC on catches in IVc and VIId for 2003 was that it should not exceed the 2002 sub-TAC, and for 2004 that it should not increase faster than the TAC for the North Sea as a whole. ACFM thought that a share of $11 \%$ on the total North Sea TAC (average share 1989-2002) would be an appropriate guide to distributing the harvesting among Downs herring and other stock components. It was expected that fishing at the recommended level would lead to a further increase in the SSB, mainly due to large recruiting year classes entering the fishery.

The final TAC adopted by the management bodies for 2003 was $400,000 \mathrm{t}$ for Area IV and Division VIId, whereof not more than $59,542 \mathrm{t}$ should be caught in Division IVc and VIId. For 2004, the TAC was raised to $460,000 \mathrm{t}$ (by 15\%) and the sub-TAC set for Division IVc and VIId was raised to $66,098 \mathrm{t}$ (by $11 \%$, representing a share of more than $14 \%$ on the total TAC). Catches of herring in the Thames estuary are not included in the TAC. The by-catch ceiling set for fleet B in the North Sea was $52,000 \mathrm{t}$ for 2003 and was reduced to $38,000 \mathrm{t}$ for 2004 (by 27\%). As North Sea autumn spawners are also caught in Division IIIa, regulations for the fleets operating in this area have to be taken into account for the management of the stock (see Section 3). For a definition of the different fleets harvesting North Sea herring see the Stock Appendix 3 and Section 2.7.2.

### 2.1.2 Catches in 2003

Total landings and estimated catches are given in the Table 2.1.1 for the North Sea and for each Division in Tables 2.1.2 to 2.1.5. Total working group catches per statistical rectangle and quarter are shown in Figures 2.1.1 a-d, the total for the year in Figure 2.1.1e. Each nation provided most of their catch data (either official landings or working group catch) by statistical rectangle.

The catch figures in Tables 2.1.1-2.1.5 are mostly official landings, but for some nations catch estimates are given by Working Group members, including unallocated or misreported catches. These figures can therefore not be used for management purposes. For corrections applied to and inconsistencies in previous year's data see Sections 1.4.1, 2.2 .3 and 2.2.4. Only Denmark and Norway provided information on by-catches of herring in the industrial fishery. These are taken in the small-meshed fishery (B-fleet) under a EU quota by Denmark and are included in the A-fleet figures for Norway. Catch estimates of herring taken as by-catch in other small-mesh fisheries in the North Sea may be an underestimate. The total catch in 2003 as used by the Working Group amounted to $450,100 \mathrm{t}$. Following the raising of the TAC for herring caught in the North Sea by more than $50 \%$, the total catch increased by $28 \%$ compared to last year. By area, catches increased in Division IVa (West) and IVb by roughly $40 \%$, decreased in Division IVa (East) by about $6 \%$, and increased by $35 \%$ in the southern North Sea (Division IVc and VIId), while the sub-TAC for the latter area was raised by almost $40 \%$.

Landings of herring taken as by-catch in the Danish small-meshed fishery in the North Sea were much lower than the by-catch ceiling set for Denmark ( $52,000 \mathrm{t}$ ), and have significantly decreased to $12,300 \mathrm{t}$ after a continuous increase between 1997 and 2002 (Table 2.1.6). In 2003, the Danish sprat fishery was carried out mainly in the second half of the year with by-catches of herring of about $6 \%(10,000 \mathrm{t})$. Herring by-catches in the Danish Norway pout fishery were estimated to be less than $4 \%$ ( 300 t ), less than $0.5 \%$ in the sandeel fishery ( 900 t ) and $8 \%$ in other industrial fisheries ( 500 t ). In the Norwegian industrial fishery, herring by-catch has decreased from $4,457 \mathrm{t}$ last year to $3,809 \mathrm{t}$. The quarterly distribution of herring by-catches in this fishery and its relative share on the total industrial landings are given in the text table below. These figures are counted against the human consumption quota.

| Quarter 1 | Quarter 2 | Quarter 3 | Quarter 4 | Total |
| :---: | :---: | :---: | :---: | :---: |
| 379 t | 1148 t | $1,793 \mathrm{t}$ | 489 t | $3,809 \mathrm{t}$ |
| $3.2 \%$ | $1.9 \%$ | $2.6 \%$ | $1.5 \%$ | $2.1 \%$ |

Misreporting of landings taken in the North Sea but reported from other areas such IIa and IIIa is still substantial, and the estimates of the total amount of misreported (including within-area misreporting) and unallocated catches have again increased compared to last year (to about $42,000 \mathrm{t}$, roughly $10 \%$ of the total catch in the North Sea).

Based on WG estimates of total catch, TACs for the human consumption fishery in Subarea IV and Division VIId have been significantly exceeded in several years. This appears to have continued in 2003: The total amount of unallocated and misreported catch remained constant last year. The largest relative discrepancies between officially reported landings and WG catch occurred in Division IVc and VIId, where TACs were exceeded by almost $100 \%$ between 1996 and 2001 (when the sub-TAC was set to $25,000 \mathrm{t}$ ). An over catch of TAC of almost $14 \%$ still occurs in these two divisions, and absolute amount of unallocated/misreported catch has increased in 2003.

The total North Sea TAC excess for the years 1995 to 2003 is shown in the table below (adapted from Table 2.1.6). Since the introduction of yearly by-catch ceilings in 1996, these ceilings have never been exceeded.

| Year | 1995 | 1996 | 1997 | 1998 | 1999 | 2000 | 2001 | 2002 | 2003 |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| TAC HC ('000 t) | 440 | 156 | 159 | 254 | 265 | 265 | 265 | 265 | 400 |
| "Official" landings HC ('000 t) ${ }^{1}$ | 443 | 170 | 162 | 253 | 275 | 267 | 275 | 282 | 414 |
| Working Group catch HC ( $\mathbf{0 0 0}$ t) | 449 | 196 | 226 | 324 | 318 | 328 | 303 | 331 | 438 |
| Excess of landings over TAC HC ('000 t) | 9 | 40 | 67 | 70 | 53 | 63 | 38 | 66 | 38 |
| By-catch ceiling ( ${ }^{\text {0 000 t) }}{ }^{3}$ |  | 44 | 24 | 22 | 30 | 36 | 36 | 36 | 52 |
| Reported by-catches (' 000 t ) ${ }^{4}$ | 67 | 38 | 13 | 14 | 15 | 18 | 20 | 22 | 12 |
| Working Group catch North Sea ('000 t) | 516 | 233 | 238 | 338 | 333 | 346 | 323 | 353 | 450 |

$\mathrm{HC}=$ human consumption fishery
${ }^{1}$ "Official" landings might be provided by WG members; they do not in all cases correspond to official catches and cannot be used for management purposes. Norwegian by-catches included in this figure.
${ }^{2}$ figure altered in 2000 on the basis of a re-evaluation of misreported catches from VIa North.
${ }^{3}$ by-catch ceiling for EU industrial fleets only, Norwegian by-catches included in the HC figure.
${ }^{4}$ provided by Denmark only.

### 2.2 Biological composition of the catch

Biological information (numbers, weight, length, catch (SOP) at age and relative age composition) on the catch as obtained by sampling of commercial catches is given for the whole year and per quarter in Tables 2.2.1 to 2.2.5. Where available, data are displayed separately for herring caught in the North Sea (including a minor amount of Western Baltic Spring-spawners taken in IVa East), IVa East (total; Western Baltic Spring spawners [WBSS] only - see Section 2.2.2; North Sea Autumn-spawners only), IVa West, IVb, VIId/IVc as well as for North Sea Autumn-spawners (NSAS) caught in Division IIIa, and the total NSAS stock, including catches in Division IIIa.

Biological information on the NSAS caught in Division IIIa was obtained using splitting procedures described in Sec. 3.2 and in the Stock Appendix 2. The total catches of NSAS (SOP figures), mean weights and numbers-at-age by fleet are given in Table 2.2.6. Data on catch numbers-at-age and SOP catches are shown for the period 1995-2003 in Tables 2.2.7 (herring caught in the North Sea), 2.2.8 (WBSS taken in the North Sea, see below), 2.2.9 (NSAS caught in Division IIIa) and 2.2.10 (total numbers of NSAS). Mean weights-at-age are given for 1991-2003 separately for the different Divisions where NSAS are caught (Tab. 2.2.11).

Note that Tables 2.2.6 to 2.2.11 (and subsequently the assessment input data) have been updated this year

- for catch year 1995-2002 following the revisions made by SG Rednose last year (see Section 1.4.1),
- the recalculation of the catch of NSAS in Division IIIa as a result of the removal of all Norwegian catch in that area,
- and to account for the changes in Swedish 2002 catch in Division IIIa distribution data, which was made available only very late during last year's WG meeting (see Section 2.2.3).

### 2.2.1 Catch in numbers-at-age

North Sea catches in numbers-at-age over the years 1990-2003 are given in Table 2.2.7. The total number of herring taken in the North Sea and the total number of NSAS have increased by $15 \%$ (to 3.3 billion fish) and by $10 \%$ (to 4 billion fish), respectively, as compared to last year. 0 - and 1 -ringers contributed $25 \%$ of the total catch in numbers of NSAS in 2003. Fig. 2.2.1. shows the relative proportions of the total catch numbers for different periods (1960-2003, 1980-2003 for the total area, and 2003 for different Divisions).

The following table summarises the total catch in tonnes of North Sea autumn spawners. After the splitting of NSAS in Division IIIa and Western Baltic Spring Spawners caught in the North Sea, and the removal of local Springspawners in the Western part of the North Sea, the amount of the total catch used for the assessment of NSAS was 480,000 tonnes:

| Area | Allocated | Unallocated | Discards | Total |
| :--- | :---: | ---: | ---: | ---: |
| IVa West | 201,631 | 14,115 | 4,125 | 219,871 |
| IVa East | 71,649 | 11,991 | - | 83,640 |
| IVb | 81,187 | $-2,401$ | - | 78,786 |
| IVc/VIId | 59,579 | 8,170 | - | 67,749 |
|  |  |  |  |  |
|  | Total catch in the North Sea | 450,064 |  |  |
|  | Autumn Spawners caught in Division IIIa (SOP) |  | 32,497 |  |
|  | Baltic Spring Spawners caught in the North Sea (SOP) |  | -2821 |  |
|  | Other Spring Spawners | -135 |  |  |
|  | Total Catch NSAS used for the assessment |  | $\mathbf{4 7 9 , 5 8 7}$ |  |

Summaries 84 t of Thames Blackwater herring caught under a separate quota and included in the catch figure for England \& Wales, and 50.8 t spring spawners caught in the Western North Sea (IVb $2^{\text {nd }}$ quarter and IVc $4^{\text {th }}$ quarter) reported by the Netherlands and included in the catch-at-age figures. Germany reported 257 t of spring spawners caught in the $2^{\text {nd }}$ and $3^{\text {rd }}$ quarter in IVaW, but these were removed from the catch-at-age figures (deducted from the official catch figures as negative unallocated catch).

### 2.2.2 Spring-spawning herring in the North Sea

Norwegian Spring-spawners and local fjord-type herring are taken in Division IVa (East) close to the Norwegian coast under a separate TAC. These catches are not included in the Norwegian North Sea catch figures given in Tables 2.1.1 to 2.1.6, but are now listed separately in the respective catch tables. The amount of these catches varied significantly between less than $1,000 \mathrm{t}$ in 2003 and $55,000 \mathrm{t}$ in 1997. Coastal Spring Spawners in the southern North Sea (e.g. Thames estuary) are caught in small quantities (usually less than 100 t ) regulated by a local TAC. The Netherlands reported increasing catches of Spring Spawners in the Western Part of the North Sea in recent years, which were included in the national catch figures and subtracted from the total catch used for the assessment of NSAS. This year spring spawners reported by the Netherlands and by Germany were treated differently (see paragraph above).

Western Baltic and Division IIIa Spring-spawners (WBSS) are taken in the eastern North Sea during the summer feeding migration. These catches are included in Table 2.1.1 and listed as IIIa type. Table 2.2.8 specifies the estimated catch numbers of WBSS caught in the North Sea, which are transferred from the North Sea assessment to the assessment of Division IIIa/Western Baltic in 1991-2003.

The method of separating these fish, using vertebral counts as described in former reports of this Working Group (ICES 1991/ Assess:15) is given in Sec. 3 and in Stock Appendix 2. For herring 2-ringers, 3-ringers, and 4+-ringers caught in the $2^{\text {nd }}$ quarter, mean vertebral counts in the transfer area (see Fig. 1.5.1) were used. Samples from the Norwegian catches that have been taken in May and June 2003 were used for the second quarter (Figure 2.2.2). For the $3^{\text {rd }}$ quarter no Norwegian samples were available for landings from the transfer area and instead the otolith-based proportions from samples of Danish commercial landings from this area were applied to the age distributions. For 1-ringers it was assumed that all fish were autumn spawners. The resulting proportion of spring spawners and the quarterly catches of these in the transfer area in 2003 are as follows:

| Quarter | 1-ringers <br> $(\%)$ | 2-ringers <br> $(\%)$ | 3-ringers <br> $(\%)$ | 4+-ringers <br> $(\%)$ | Catch in the transfer <br> area $(\mathrm{t})$ | Catch of WBSS in the North Sea <br> $(\mathrm{t})$ |
| :--- | :---: | :---: | :---: | :---: | :---: | :---: |
| Q 2 | $0 \%$ | $0 \%$ | $8 \%$ | $14 \%$ | 11,732 | 1,319 |
| Q 3 | $0 \%$ | $0 \%$ | $25 \%$ | $16 \%$ | 9,545 | 1,502 |
| total |  |  |  |  | 21,277 | 2,821 |

The quarterly age distribution in Subdivision IVa East was applied to the catches of the second and third quarters in the whole area. The numbers of Spring-spawners by age were obtained by applying the estimated proportion by age.

### 2.2.3 Data revisions

A number of data revisions have been applied to the assessment input data set at this year's WG meeting. The Study Group on the Revision of Data for North Sea Herring (SG Rednose, see Sec. 1.4.1) delivered its report in autumn 2003 (ICES 2003/ACFM:10). SG Rednose reworked catch and catch-at-age data for 1995-2001, the results affected the catch tables (Tables 2.1.1 to 2.1.6) and historical catch-at-age information (Tables 2.2.6 to 2.2.11). These have been updated this year along with the assessment input files. An error was obtained in one of the tables delivered by SG Rednose: mean weights for total North Sea Autumn Spawners in 1995 were not calculated properly. This has been corrected also in the SG Rednose-report.

A second major revision of the splitting between NSAS and WBSS in Division IIIa, based on new information of the distribution of Norwegian catches in Divisions IIIa and IVa(E), has been included in this year's NSAS assessment for the period from 1995 onwards. Since last year, it is assumed that all Norwegian catch in Division IIIa is actually taken in the North Sea. This affected the numbers and mean weights of NSAS in Division IIIa, as most of the older and heavier fish appeared to have been taken by the Norwegian fleet. Splitting data is still not completely reworked for the earlier period and NSAS assessment data could therefore not be updated for 1991 to 1995.

Sweden reported amendments to their catch figures for Division IIIa very late during last year's WG meeting. Corrections to the splitting between NSAS and WBSS in that area had an effect on the data for NSAS and while corrected data was only partly displayed and used in last year's report, all tables have now been updated.

Minor corrections and amendments have again been applied to the catch tables. France revised its catch figures for 2001 (adding 195 t in Division IVb and 170 t in IVc/VIId). Norway delivered final catch figures for 1999 and 2000 to ICES, however, the WG felt that data delivered by WG members to SG Rednose last year would be more suitable to use. The summary ("The Wonderful") table (Tab. 2.1.6) has been updated with information on the distribution of NSAS and WBSS catch on the different fleets operating in Division IIIa for 1995-2001. This information was not available before SG Rednose concluded.

Exploratory assessment runs demonstrated that none of the corrections applied had significant impact on the historic perception of the NSAS stock (see Sec. 2.10.). However, it had an influence on the predictions and removed some variability of the catch-at-age information, which was attributed to arbitrary raising procedures used in the past.

### 2.2.4 Quality of catch and biological data, discards

As in previous years, some nations provided information on misreported and unallocated catches of herring in the North Sea and adjacent areas. Catches made in Division IVa were mainly misreported to Division IIIa and IIa, but misreporting also occurred from IIIa to IVa, within Area IV, and from Division VIId to IVb. The Working Group catch, which includes estimates of discards and misreported or unallocated catches (see Section 1.5), was estimated to exceed the official catch significantly (by about 10\%). An analysis conducted in 2002 (ICES 2002/ACFM:12) indicated that this figure could be much higher if the mean rate of misreporting and unallocated catch for nations reporting this would be applied to the whole North Sea catch. This corroborates suggestions of the Study Group for Herring Assessment Procedures (ICES 2001/ACFM:22), that a significant uncertainty of the total catch figure exists since the reopening of the fishery in 1980.

Discards were so far considered to be unproblematic in the North Sea herring fishery (less than 5\% of the total catch, based on observer sampling programs). In 2002 for the first time, onboard sampling by two nations observed substantial discards of herring in the mackerel fishery in the $3^{\text {rd }}$ and $4^{\text {th }}$ quarter in Division IVa (W). At this time, the quotas for herring were already taken and herring occurred in mixed schools with mackerel. The discard figure finally used for the assessment was $17,000 \mathrm{t}$, but herring discards of all fleets in 2002 could have been as high as $50,000 \mathrm{t}$. For 2003, the herring TAC has been increased by $50 \%$, and at the same time the mackerel TAC has been reduced by more than $5 \%$. Sampling of the same fleets in 2003 demonstrated that - as anticipated - the total amount of discards may have been reduced to about $5 \%$ of the total herring catch. Discards occurred mainly in the mackerel fishery in the $1^{\text {st }}$ and $4^{\text {th }}$ quarter, and to less extent as slippage in the directed herring fishery in the $3^{\text {rd }}$ quarter. While most of the herring was discarded in the $4^{\text {th }}$ quarter due to a lack of herring quota, there is concern that herring is also discarded earlier in the year when the quota is still not taken and fish could have been landed legally. The final discard figure used for the assessment in 2003 is 4125 t , based on the raised figure for one sampled fleet. As discards are likely to occur in all nation's fisheries, this figure is certainly an underestimate and could be more than 20,000 t.

In general, sampling of commercial landings for age, length and weight has again improved as compared to last year (Table 2.2.12). The European Union implemented a new sampling regime in 2002, obliging member states to meet specified overall sampling levels. This year, $85 \%$ of the catch was sampled (2002: 81\%), and the number of age readings has again been increased by $34 \%$. It should be observed that "sampled catch" in Table 2.2.12 refers to the proportion of the reported catch to which sampling was applied. This figure is limited to $100 \%$ but might in fact exceed the official landings due to sampling of discards, unallocated and misreported catches.

However, more important than a sufficient overall sampling level is an appropriate spread of sampling effort over the different metiers (each combination of fleet/nation/area and quarter). Of 108 different reported metiers, only 43 were sampled in $2003(40 \% ; 2002: 47 \%)$. Some of them, however, yielded very little catch. The recommended sampling level of more than 1 sample per $1,000 t$ catch has been met only for 34 metiers (2002: 29). For age readings (recommended level $>25$ ageings per $1000 t$ catch) this is only slightly worse: only 29 metiers appear to be sampled sufficiently (2002: 21). The catch of France, UK/England and Wales, Sweden, and the Faroe Islands from the North Sea (combined share $13 \%$ of the total North Sea catch) has not been sampled. Information on catches landed abroad was also not available or could not be used. While it is known that by-catches of herring in other than the directed human consumption fisheries occur, most countries have not implemented a sampling scheme for monitoring these fisheries.

In this respect, there is still a need to improve the quality of the catch data for the North Sea herring. It appears that in some instances the new EU data collection directive could even lead to a deterioration of sampling quality, because it does not assure an appropriate sampling of different metiers. This introduces uncertainties in the biological composition of the catches, which affects the quality of the assessment. The WG therefore recommends that all metiers with substan-
tial catch should be sampled (including by-catches in the industrial fisheries), that catches landed abroad should be sampled and information on these samples should be made available to the national laboratories (see Section 1.5).

### 2.3 Fishery Independent Information

### 2.3.1 Acoustic Surveys in VIa(N) and the North Sea in July 2003

Six surveys were carried out during late June and July 2003 covering most of the continental shelf north of $52^{\circ} \mathrm{N}$ in the North Sea and $56^{\circ} \mathrm{N}$ to the west of Scotland to a northern limit of $62^{\circ} \mathrm{N}$. The eastern edge of the survey area is bounded by the Norwegian, Danish, Swedish, German and Dutch coasts, and to the west by the shelf edge at approximately 200 m depth. The individual surveys and the survey methods are given in the report of the Planning Group for Herring surveys (ICES 2004/G:05). The vessels, areas and dates of cruises are given below and in Figure 2.3.1.1:

| Vessel | Period | Area |
| :--- | :--- | :--- |
| FV Enterprise | 01 July -21 July | $56^{\circ}-60^{\circ} \mathrm{N}, 3^{\circ}-7^{\circ} \mathrm{W}$ |
| R.V Sarsen | 1-22 July | $56^{\circ} 30^{\circ}-61^{\circ} \mathrm{N}, 2^{\circ}-6^{\circ} \mathrm{E}$ |
| Scotia | 27 June -20 July | $58^{\circ}-62^{\circ} \mathrm{N}, 4^{\circ} \mathrm{W}-2^{\circ} \mathrm{E}$ |
| Tridens | 23 June -18 July | $54^{\circ} 30-58^{\circ} \mathrm{N}$, west of $3^{\circ} \mathrm{E}$ |
| Walther Herwig III | 26 June -13 July | $52^{\circ}-57^{\circ} \mathrm{N}$, east England $/ 3^{\circ} \mathrm{E}$ |
| Dana | 27 June - 8 July | North of $57^{\circ} \mathrm{NS} \& 56^{\circ} \mathrm{N}$, Kattegat east |
|  |  | of $6^{\circ} \mathrm{E}$ |

The data has been combined to provide an overall estimate. The areas covered and dates of surveys are shown in Figure 2.3.1.1. Estimates of numbers-at-age, maturity ogive and mean weights-at-age are calculated as weighted means of individual survey estimates by ICES statistical rectangle. The weighting applied is proportional to the survey track for each vessel that has covered each statistical rectangle. The data has been combined and the estimate of the stock surveyed is shown in Tables 2.3.1.1-3 by ICES subarea for North Sea autumn spawning herring. This year the area has been extended south to provide better coverage of sprat. A very small amount of herring was also found in this area, the contribution was less than $0.05 \%$ of the total biomass.

## Combined Acoustic Survey Results:

The estimate of North Sea autumn spawning herring SSB is 3.0 million tonnes which is 17,300 millions herring (Table 2.3.1.4). This data series is used as a relative index in the assessment of North Sea herring because the absolute abundance cannot be used directly due to uncertainties in target strength. The North Sea survey is consistent with previous years, giving a total adult mortality of about 0.45 over the last 3 years, which is similar to the estimates from the assessment. The North Sea herring SSB rose from 2.4 million tonnes in 2001 (Table 2.3.1.5) to 2.9 million tonnes in 2002 and again to 3.0 million tonnes in 2003 . However, growth of the 2000 year class seems to be slower than for previously observed year classes. The herring are 1.5 cm smaller, and 20 g lighter than the similarly abundant 1998 year class at the same age (2-rings). Only $43 \%$ of this year class are mature at 2 -ring compared to $66 \%, 77 \%$ and $86 \%$ for 1997, 1998 and 1999 year classes. If this year class had grown and matured as previous years, to $76 \%$ mature, the spawning stock biomass would have been $27 \%$ higher at 3.8 million tonnes. The survey shows again the two exceptional year classes of herring (the 1998 and 2000 year classes) in the North Sea, which is consistent with the observation of exceptionally large year classes observed in the MIK and IBTS surveys (ICES 2001a). The 2003 estimate of the 2000 year class suggests that it may be higher than the 1998 year class at 1.5 times at age 2 -ring.

The numbers and biomass of adult autumn spawning herring can be seen in Figures 2.3.1.2, the numbers at 1, 2 and $3+$ rings in Figure 2.3.1.3. The spatial distribution of mean weight at 1 and 2 ring, and fraction mature at 2 and 3 ring are given in Figure 2.3.1.4. These show a considerable spatial trend which is observed each year, with larger more mature fish found in the North and smaller less mature fish found in the south and particularly the eastern north Sea. The relative spatial distributions of adult and juvenile autumn spawning herring can be seen in Figures 2.3.1.5 and 2.3.1.6 respectively. The mean weights-at-age and the fraction mature are used in the assessment, the influence of the precision of this data were discussed in detail in section 2.10 last year.

### 2.3.2 Larvae surveys

In 2003/04 The Netherlands and Germany participated in the surveys and managed to cover seven out of ten areas. The survey effort is comparable to previous years. The areas and time periods (including numbers of samples, vessel-days in sampling and area coverage) are given in Table 2.3.2.1 and Table 2.3.2.2. The spatial extent of the surveys is shown in Figures 2.3.2.1-2.3.2.7. The historical background of the larvae surveys and the methods used for abundance calculation are described in the handbook for quality control. A more detailed description is available in the manual for the international herring larvae surveys in the North Sea (ICES 2004 CM/G:05).

Results from the survey around the Orkney/Shetlands show the common pattern of a large spatial extension of newly hatched larvae and high abundance estimates to the east of the Orkneys (Fig. 2.3.2.1). The overall abundance is $50 \%$ less than 2002 and a quarter of 2001 (which was the highest record ever observed in that period). Unfortunately no information is available about larval abundance in the first half of September. Peak spawning may have shifted towards the beginning of September during the past two years. This is supported by a certain amount of larger larvae found in the samples.

In the Buchan area larval distribution is more restricted (Fig. 2.3.2.2), but the Larval Abundance Index (LAI) increased substantially and is twice as high as in 2002.

Two periods were covered in the Central North Sea (CNS, Fig. 2.3.2.3 and 2.3.2.4). Both yielded strong abundance estimates. The LAI estimates for this area have risen continuously over the last six years.

Abundance estimates from the three surveys in the Southern North Sea (SNS) have increased substantially in comparison to former years. Spawning started in the second half of December in a restricted area in VIId and then spread out into VIc during January (Fig. 2.3.2.5-2.3.2.7). As usual, an area from the French coastline to the middle of the Channel contributed most to the abundance index in the Southern North Sea.

The model for the Multiplicative Larval Abundance Index (MLAI) was fitted to abundances of larvae less than 10 mm in length ( 11 mm for SNS) (Table 2.3.2.3),. The analysis of variance and the parameter estimates are given in Table 2.3.2.4. The updated MLAI time-series is shown in Table 2.3.2.5. The estimated trend in spawning stock biomass from this model fit is plotted in Figure 2.3.2.8 versus the SSB values obtained from the ICA runs of the Herring Assessment Working Group (ICES 2003 ACFM:17).

The results of two surveys (CNS, $2^{\text {nd }}$ period, and SNS, $1^{\text {st }}$ period) are influenced by large catches at single stations. More than 12,000 larvae per $\mathrm{m}^{2}$ were caught at these two stations. They contributed roughly $50 \%$ to the respective LAI values. When excluded, the remaining LAI is 5,207 instead of 12,018 for the CNS and 5,560 instead of 12,048 in case of the SNS (Numbers ${ }^{*} 10^{9}$ ). These still represent high LAI estimates. As a general rule, additional stations should be inserted in areas with high larval concentrations to enable average calculation. Unfortunately this wasn't done here. However, there are some routines in the MLAI calculation to make it robust against patchiness effect. Exclusion of the two very high abundance catches leads to a difference of $13 \%$ on the MLAI estimate. With comparison to the general noise in survey data this figure is minimum. Thus no data were excluded from the MLAI calculation. Both the LAI per area as well as the MLAI from the larvae surveys in 2003/2004 indicate that the SSB has increased when compared to last years WG estimate.

### 2.3.3 International Bottom Trawl Survey (IBTS)

The International Bottom Trawl Survey (IBTS) started out as a young herring fish survey in 1966 with the objective of obtaining annual recruitment indices (1-ringers) for the combined North Sea herring stocks. It has been carried out every year since, and presently the survey provides recruitment indices not only for herring, but also for roundfish species as well. Examinations of the catch data from the $1^{\text {st }}$ quarter IBTS have shown that catch during the surveys also indicates abundances of the adult stages of herring. From 1977 sampling at night with fine-meshed nets (MIK) was implemented, and the catch of large herring larvae was used for estimation of 0 -ringer abundance in the survey area. Hence, a series of herring abundance indices are available from this survey programme.

Due to uncertainties about standardisation of the English trawl catches in 2004, these catches are not included in the calculations of $1-5+$ ringer indices for $1^{\text {st }}$ Quarter 2004. The WG recommends that the IBTS WG evaluates the inclusion of the English 2004 catches in future calculations of IBTS indices. The standard sampling gear in the sampling programme for 0-ringers is a fine-meshed ring net. However, the Scottish sampling is carried out using a modified frame version of a larger opening. In the calculation of 0 -ringer indices, the differences in gear size is taken into account, but in order to avoid potential catch-ability differences, the WG recommends a full standardisation of the sampling programme, hence, that Scotland changes gear to the 2-metre ring version with standard netting.

### 2.3.3.1 Indices of 2-5+ ringer herring abundances

Fishing gear and survey practices were standardised from 1983, and herring abundance estimates of 2-5+ ringers from 1983 onwards has shown the most consistent results in assessments of these age groups. This series is then used in North Sea herring assessment. Table 2.3.3.1 shows the time-series of abundance estimates of 2-5+ ringers from the $1^{\text {st }}$ quarter IBTS for the period 1983-2004, when Table 2.3.3.2 contains area-disaggregated information on the IBTS indices for year 2004.

### 2.3.3.2 Index of 1-ringer recruitment

The 1-ringer index of recruitment is based on trawl catches in the entire survey area. Indices are available for year classes 1977 to 2002 (Table 2.3.3.3). This years estimate of the 2002 year class strength (979.5) indicates a very low recruitment, among the lowest on record.

Figure 2.3.3.1 illustrates the spatial distribution of 1-ringers as estimated by the trawling in February during 2002, 2003 and 2004. In 2004 the main concentrations of 1-ringers were found in the south- eastern part of the North Sea. The mean length of the 1 -ringers in this area is relatively small, between 10 and 14 cm (Figure 2.3.3.2.).

The Downs herring hatch later than the other autumn spawned herring and generally appears as a smaller sized group during the $1^{\text {st }}$ quarter IBTS. A recruitment index of smaller sized 1-ringers is calculated based on abundance estimates of herring $<13 \mathrm{~cm}$ (see discussion of procedures in earlier reports (ICES CM 2000/ ACFM:12, and ICES CM 2001/ ACFM:12)).

Table 2.3.3.3 includes abundance estimates of 1-ringer herring smaller than 13 cm , based on a standard retrieval of the IBTS database, i.e. the standard index is in this case calculated for herring $<13 \mathrm{~cm}$ only. Indices for these small 1ringers are given either for the total area or the area excluding division IIIa, and their relative proportions are also shown. In the time-series, the proportion of 1 -ringers smaller than 13 cm (of total catches) is in the order of $20 \%$, and the contribution from division IIIa to the overall abundance of $<13 \mathrm{~cm}$ herring varies markedly during the period. (Table 2.3.3.3)

This years group of 1-ringers has a high proportion of herring $<13 \mathrm{~cm}$ ( $41 \%$ of all 1-ringers in total area). These are almost exclusively found in the North Sea area (Table 2.3.3.3)

### 2.3.3.3 The MIK index of 0-ringer recruitment

The 0 -ringer index is based on depth-integrated hauls with a 2 metre ring-net (the MIK). Index values are calculated as described in the WG report of 1996 (ICES 1996/Assess:10). The series of estimates is shown in Table 2.3.3.4, the new index value of 0 -ringer abundance in 2004 is estimated at 47.3.

This estimate of the 2003 year class indicates a very low recruitment, of the same size as last years recruitment estimate. The 0 -ringers were concentrated in north-western areas of the North Sea, with highest concentrations off the Scottish coast into the north/central part of the North Sea (Figure 2.3.3.3). This distribution pattern differs from the distribution of the preceding two year classes of 0-ringers, also shown in Figure 2.3.3.3.

### 2.4 Mean weights-at-age and maturity-at-age

### 2.4.1 Mean weights-at-age

The mean weights-at-age of fish in the catches in 2003 (weighted by the numbers caught) are presented by ICES Division and by quarter in Table 2.2.11.

Table 2.4.1.1 shows the historic mean weights-at-age (wr) in the North Sea stock during the 3rd quarter in Divisions IV and IIIa for the period 1993 to 2003. These values were obtained from the acoustic survey. The data for 2003 are taken from Table 2.3.1.4. In this quarter most fish are approaching their peak weights just prior to spawning. The spatial distribution of mean weight for 1 and 2-ringers are given in Figure 2.3.1.4. The spatial variability of mean weight is considerable. For comparison the mean weights-in-the-catch from the last ten years are also shown in Table 2.4.1.1 (from Section 2.2.1 for the 2003 values). For 3-ringers and older the mean weights in both the catch and the acoustic survey are generally close to the long-term mean. For 2-ring herring both the catch and the acoustic survey show mean weights that are the lowest for the last 10 years supporting the view that the exceptional 2000 year class is growing slowly. The influence of this low mean weight on the state of the stock is discussed in section 2.10, Quality of the assessment. The weight of 1-ring herring is rather variable, particularly in the catch, which this year shows a high value, the acoustic survey shows a value about $10 \%$ below the mean.

### 2.4.2 Maturity Ogive

The percentages of North Sea autumn-spawning herring (at age) that spawned in 2003 were estimated from the July acoustic survey. The values were determined from samples of herring from the research vessel catches examined for maturity stage, and raised by the local abundance. All herring at maturity stage between 3 and 6 inclusive (using an 8 -stage scale) in June or July were assumed to spawn in the autumn. The method and justification for the use of values derived from a single years data was described fully in ICES (1996/Assess:10). The values for 2- \& 3-ringers taken from the acoustic survey results (Table 2.3.1.4.) For 2-ringers the proportion mature was much lower than last year, and is the lowest in the time-series, though low values have been observed in 1992 and 1993. The data were examined carefully for errors and it was concluded that the 2000 year class has developed slowly since July 2002. Fraction mature, mean weight and mean length-at-age and by year are shown in Figure 2.4.2.1. This year class, possibly the largest in recent years and the first large one competing with an already large herring stock biomass, has grown more slowly than earlier year classes. Slow growing and immature herring were found mostly in the eastern central North Sea. The spatial distribution of fraction mature is shown in Figure 2.4.2.2. The proportion of mature 3-ringers was also above the long-term mean for the period. The percentages are given in Table 2.4.2.1. The influence on the assessment of the low fraction mature at 2-ring is discussed in Section 2.10, Quality of the assessment.

Information on the development in North Sea herring recruitment is available from the two IBTS indices, the 1-ringer and the 0 -ringer index. Further, the ICA assessment provides estimates of the recruitment of herring in which information from the catch and from all fishery independent indices is incorporated.

### 2.5.1 Relationship between the MIK 0-ringer and the IBTS 1-ringer indices

The 0-ringer MIK index predicts the year class strength one year before the information is available from the IBTS 1ringer estimates. The relationship between year class estimates from the two indices is illustrated in Figure 2.5.1 and described by the fitted linear regression. Last years prediction of a very small 2002 year class was confirmed by this year's IBTS 1-ringer index of the year class. The good correlation between the indices is also evident when comparing the respective trends in indices during the period (Figure 2.5.2).

### 2.5.2 Trends in recruitment from the assessment

Recruitment is estimated in the ICA-assessment, and in Figure 2.5.3 the trends in 1-ringer recruitment based on 2004 assessment is illustrated. The recruitment declined during the sixties and the seventies, followed by a marked increase in the early eighties. After the strong 1985 year class recruitment declined again until the strong year classes 1998-2001. However, the 1 -ringer recruitment of the recent 2002 year class is very low, and the 0 -ringer recruitment based on the MIK index indicates that this year class will be followed by another low year class 2003. The present ICA estimates of 1-ringer recruitment are 19.4 and 7.6 no 109 for year classes 2001 and 2002 respectively, while the estimates for 0 ringers are 54.0, 21.2 and 17.4 no 109 for year classes 2001, 2002 and 2003 respectively.

### 2.6 Assessment of North Sea herring

### 2.6.1 Data exploration and preliminary results

### 2.6.1.1 Choice, properties and effect of indices for North Sea herring

Acoustic, Bottom trawl (IBTS), MIK and Larvae (MLAI) surveys are available for the assessment of herring. The surveys and the years for which they are available are given in Table 2.6.1.1 (and appendix 2). A series of basic analyses was conducted last year to check the basic utility of the surveys available (ICES 2003/ACFM: 17). The analysis showed that the surveys had self-consistency in the abundance estimates of successive cohorts. There was also agreement between the different indices in the same year. The 1st and 3rd quarter IBTS surveys indicate good agreement for the 0 -ring herring and the 1 st quarter IBTS and acoustic survey show agreement on 1 -ring. However, in general the different surveys seem to contain different information for older rings.

An analysis of the sampling error by ring by survey (using bootstrap re-sampling as the method, ICES CM 2001/ACFM:22) showed that sampling error is lowest for Acoustic survey at 3 and 4-ring and the MIK survey (IBTS 1Q 0-ring). The sampling error is higher but still reasonable for the IBTS 1st Quarter 1-ring, the Acoustic 2-ring and 5-8 ring and the MLAI SSB index. The IBTS 3rd Quarter index and the IBTS 1st Quarter 3-5 ring index have relatively high sampling errors. Generally, the analysis of variance and correlation indicates that the MLAI provides a good SSB index, the acoustic survey provides good information from 1-8 ring and the IBTS 1st Quarter from 0 and 1-ring. The IBTS 1st Quarter 2-5 ring is useful but noisy, as is the IBTS 3rd Quarter 0-ring index although the latter is still considered too noisy to be included in the assessment. The IBTS 3rd Quarter 1-5 ring index is not consistent. Currently, the MLAI, Acoustic and IBTS 1st Quarter indices are used in the assessment.

The usual assessment tool for the assessment of North Sea herring is ICA. The 4 tuning indices used last year were run separately with the updated catch data, to determine the signal from the individual tuning indices (Figure 2.6.1.1a). The settings were the same as last year (see section 2.6.2). The acoustic survey (1-9 rings), the IBTS (1-5 rings), and the MLAI (as an SSB index) gave very similar perceptions of fishing mortality on the reference age of the separable model (4-rings) with all estimates within the $90 \%$ confidence intervals of the others. The MIK index gave a slightly lower estimate, which was below the confidence interval of the acoustic survey. This index contains information for only the youngest age class and such good agreement by tuning with only the 0 -group must be viewed as supporting the utility of these datasets. The assessment combining all the indices was within the $90 \%$ confidence intervals of all of the individual assessments from the indices (Figure 2.6.1.1a).

The acoustic, IBTS and MLAI series suggest a mean $\mathrm{F}_{(2-6)}$ between 2.0 and 2.4 (Figure 2.6.1.1b). All of these are close to the assessment combining all the series. The scatter of 100 estimates of SSB and mean $\mathrm{F}_{(2-6)}$ from bootstrapping the residuals of the model with all the tuning indices combined, show that the individual estimates from each tuning series are within that scatter of the estimates (Figure 2.6.1.1c).

### 2.6.1.2 Selection of weighting of indices in the assessment of North Sea herring

The HAWG in 2002 moved from arbitrary index weighting as used for the previous 6 years (1996-2001) to a more objective method. This new method was developed from the work of the ACFM study group SGEHAP (ICES CM
2001/ACFM:22) which had one of its objectives to try to rationalise the survey index weighting in the assessment. The analysis carried out is described in last year's report (ICES 2003/ ACFM:17) and in section 2.10 . The weighting values are given in Table 2.6.1.2. The weightings applied account for sampling error of the surveys. The WG in 2002 selected index weighting which both minimised the variability in the assessment output but also reduced the retrospective revision of management parameters (F, SSB and recruitment). However, they could not find a method that minimised the revision of all of these parameters but selected the one that performed best for two out of three. This was done by downweighting the influence of catch of 0 and 1 -ring catch in the assessment (Table 2.6.1.2).

The previous WG made an extensive review covering both inverse variance and structural errors, and it considered that the inverse variance method provided the better method. This process meant that the weighting of surveys and catch is fixed and as the sensitivity of the assessment to these weighting values has been greatly studied in recent years, this WG further discusses the implication of these assumptions in section 2.10 . The weights express the WG view that the young herring are best estimated with MIK and IBTS surveys, the older herring are best evaluated through the acoustic survey and the SSB should be estimated through the MLAI.

### 2.6.1.3 Period of separable constraint

Changes in the regulations in 1996 have affected the various components of the fishery differently. Recent meetings of this WG split the separable period into two different periods: 1992-1996 and 1997 onwards. In the WG 2001 it was considered that the number of years after the change in selection was long enough to use only a single separable period of four years. In the 2002 and 2003 WGs a separable period of 5 years was used. An exploration of a 4, 5 or 6 year separable period with current data ( 2004 WG ) showed no important differences in the model fit or outputs. The estimation of F at reference age (4-rings) was not significantly different (Figure 2.6.1.2a), although the confidence interval of the 4 year separable period estimate was slightly broader. There was negligible difference in mean $\mathrm{F}_{2-6}$ and SSB when using a 4,5 or 6 year separable period (Figure 2.6.1.2 b \& c). So the 5 year separable period was maintained in the current assessment.

### 2.6.1.4 Comparison of assessment models

ICA has been used for at least the last eight years for the assessment of North Sea herring. It was felt that after the findings of the recent WGMG (ICES CM2003/D:03), the performance of ICA should be compared with another regularly used assessment model, XSA. Concern at WGMG was raised about the instability in the selection patterns at older ages impacting on the earlier part of the time-series. The approach used was to choose XSA settings that reflect as many of the assumptions of the ICA model of North Sea herring. The model settings are given in Table 2.6.1.3 and the summary of the results in Table 2.6.1.4.

In a situation of a trend in F , or highly variable F in recent years, XSA is very sensitive to the number of ages used for F shrinkage. Dependency on the actual level of shrinkage, compared to number of ages used was much smaller. The XSA assessment is very consistent with the ICA assessment (Figure 2.6.1.3). The slightly higher estimate of F and lower estimate of SSB in the terminal year by XSA can be explained by the exclusion of the MLAI in the XSA (which cannot use biomass indices) and the effect of shrinkage during a period of declining $F$, increasing it towards the mean of recent values.

### 2.6.1.5 Model fit and residuals.

Examination of the residuals of the catch and surveys shows similar patterns as last year. The weighted residuals of the separable model fit show a random distribution by ring and year of small residuals (Figure 2.6.1.4). The residuals of the acoustic survey show a random pattern in the most heavily weighted ages (1-3 rings, Figure 2.6.1.5) with a group of negative residuals at older ages in recent years. The residuals are small but clearly non-random. As mentioned above this is similar to last year's assessment and reflects a different signal in the surveys compared to the catch. The surveys are suggesting a slightly higher fishing mortality than given by the catch information (section 2.3.1). Whilst these differences are very small, they are explored here to maintain the quality of the assessment.

A difference between the surveys and the catch has been crudely compared by using the change in the ratio between the survey estimates of total abundance against the catch in numbers (Figure 2.6.1.6). The relationship changed in 1996, as the management of the stock changed. The increase after 1996, suggests that proportionately more fish were being caught in the surveys compared to the catch. This crude method of analysis, which reflects changes in the exploitation pattern, is based on a ratio, and thus it is difficult to explain which of the two variables has the causal link to any properties seen.

Plotting the log catch ratios from 1993 in the catch and comparing them to the $\log$ abundance ratios from the acoustic survey (Figure 2.6.1.7) shows a declining trend in the total mortality experienced by the stock, this is particularly marked in the 2 and 4 -ring fish. This suggests that total mortality is declining (table 2.6.1.5). The slopes through the catch ratios (declining rate of total mortality, table 2.6.1.5) are steeper for the catch than in the acoustic survey, sug-
gesting that the estimate of total mortality from the acoustic survey is reducing slower than in the catch. However it is probable that these declining slopes are not significantly different and testing the slopes of data with these properties is very difficult. But again, this supports the concept that the acoustic survey does have a different trend in catchabilities compared to the landings and slightly different impressions of F are coming from different sources. This can occur for at least two reasons. Firstly the catchabilities of the surveys may be decreasing, secondly that there has been a change in the reporting of the true catch. As the North Sea herring quota increases, it has been anecdotally reported that the catches are not actually increasing as fast, but the level of misreporting is declining. An increase in actual landings would have a negative impact on the market price of herring. Hence, the increase in quota is being used to increase the proportion of catch being officially reported. This may result in the real catch remaining relatively stable, whilst scientists assume an increase in catch. A simulation exercise showed that this pattern of negative residuals in the surveys (seen in Figure 2.6.1.5) could be created by assuming that a prolonged period of misreporting was being brought to an end.

As stated earlier the negative block in the weighted residuals of the acoustic survey is very small. A possible mechanism for their appearance has been proposed and found to be practical. However these weak, but not random blocks of residuals, do not have a major or detrimental effect on the other diagnostics of the stock assessment.

### 2.6.1.6 Conclusions of exploration of the assessment.

In terms of the assumptions about the separable period, the utility of the tuning indices and the weighting of the indices and catch, this assessment appears robust. Preliminary analysis suggests that the recent decline in mortality shown by the acoustic survey is less than the decline shown by the catch. The different mortality signals should be monitored in the future. However as the rest of the assessment appears relatively stable and comparable with another assessment technique (XSA, section 2.6.1.4), and the model residuals were small, it was concluded that the assessment method would be maintained as last year, with comparable settings, tuning indices and weightings. The consistency of the assessment is further discussed in section 2.10.

This formulation of the assessment is also supported by the recent external and independent review of the North Sea herring assessment carried out for the North Sea Commission, where the consistency, precision and quality of the assessment were judged as credible and fully acceptable as a tool for management advice.

### 2.6.2 The stock assessment

### 2.6.2.1 The model used

This stock remains on the ACFM observation list, however following a full examination of the settings of the model, the assessment conforms to an update assessment. The assessment of the stock was carried out by fitting the integrated catch-at-age model (ICA) including a separable constraint over a five-year period as explained above (Patterson, 1998, Needle 2000), see section 1.6 and the quality handbook. The input data are shown in table 2.6.2.1.

### 2.6.2.2 Results

The ICA output is presented in Tables 2.6.2.2 and 2.6.2.3, with model fit and parameter estimates in Table 2.6.2.4, and Figures 2.6.2.1-2.6.2.19. Uncertainty analysis of the final assessment is presented in Figure 2.6.2.20, although this only reflects the uncertainty in fitting the model and does not include uncertainty in the model specification. Estimates of fishing mortality at 2-6 ringer in 2003 vary in a similar way to last year, between 0.21 and 0.28 ( 25 and 75 percentile respectively) and SSB in 2003 between 1.59 and 1.92 million tonnes. There appears to be a relatively good agreement between the point estimates of the final assessment and the median values of the ICA bootstrap realisations. Long-term trends in yield, fishing mortality, spawning stock biomass and recruitment are given in Figure 2.6.2.21.

The spawning stock at spawning time 2003 is estimated at approximately 1.74 million tonnes. The abundance of 0 -ring fish in 2003 and 2004 are low (the 2002 and 2003 year classes) with the estimate for 0-rings in 2004 being the lowest since 1980. The strong 1998 and 2000 year classes are still evident in the population, with the 2000 year class at 3 ring in 2004 being the highest in the series since 1964.

Fishing mortality on 2-6 ringer herring in 2003 is estimated at around 0.24 , and on $0-1$ ringer herring at 0.04 . The value of F for 2002 agrees with last year's assessment and is also 0.24 .

Analytic retrospective analysis of the assessment (Figure 2.6.2.22) shows that the perception of the state of the stock in 2002 does not change with the addition of 1 years extra data. Assessments in 1994 and 1995 agree with the current perception, and the bias in the intervening years may be due to the use of a 5 year separable period through the management change in 1996. The retrospective selection patterns show a marked change in 2001 (Figure 2.6.2.23), this is probably due to separable period moving back into the time of the change in the catching behaviour and management of the fishery in 1996. The perception of F at reference age of the separable model (4-ring) in 1999 has been very similar (Figure 6.2.2.24).

### 2.7.1 2.7.1 Method

The program used (MFSP) was developed two years ago in the HAWG and was used in a slightly amended form at last years meeting (Skagen; WD to HAWG 2003). This year, it was decided that the slow growth and maturation of the large 200 year class needed to be taken into account. The program was therefore amended to use different weights and maturities in each of the prediction years. The standard tool that currently is available for short-term predictions (the MFDP program) has some limitations with regard to management options that can be covered. In particular, when varying the fishing mortality for one fleet, the fishing mortalities for the other fleets are assumed constant at status quo F. For the North Sea herring, managers have agreed to constrain the total outtake at levels of fishing mortalities for ages 01 and 2-6, and need options to show the trade-off between fleets within those limits. The MFSP program was developed to cover these needs.

### 2.7.2 Input data

## Fleet Definitions

The current fleet definitions are:

## North Sea

Fleet A: Directed herring fisheries with purse seiners and trawlers. By-catches in industrial fisheries by Norway are included.
Fleet B: Herring taken as by-catch under EU regulations.

## Division IIIa

Fleet C: Directed herring fisheries with purse seiners and trawlers
Fleet D: By-catches of herring caught in the small-mesh fisheries
The fleet definitions are the same as last year.

## Input Data for Short-term Projections

All the input data for the short-term projections are shown in Table 2.7.1, which is the input file for the predictions.

Stock Numbers: For the start of 2004 the total stock number was taken from ICA (ica.n - file)
For 2005 and 2006, the recruitment was set to 50443 million which is the geometric mean of the recruitments of the year classes 1981-2000.

Fishing Mortalities: Selection by fleet at age was calculated by splitting the total fishing mortality in 2003 for each age proportional to the catches by fleets at that age. These fishing mortalities were used for all years in the prediction.

Mean Weights-at-age in the stock: Since the weights used in the assessment are already smoothed, the values for 2003 (Table 2.6.2.2) were used in the prediction.

Maturity-at-age: The average maturity-at-age for 2000 to 2002 was used (Table 2.6.2.2), except for the 2000 year class. For this year class, which so far has matured more slowly than usual, the maturity of 3-ringers in 2004 was taken to be the maturity-at-age 2 in 2003 ( 0.43 ) raised by a factor of 1.31 , which is the mean relative increase in maturity from age 2 to age 3 in the period 1991-2002. For 2005 and 2006, this year class was assumed to be fully mature.

Mean weights in the catch by fleet: The mean weights by fleet for the years $2000-2002$ were used, except for the 2000 year class, which appears to have been slower growing than usual. For this year class, the ratio between the weight-at-age 2 in 2003 and the average weight-at-age 2 was maintained for 2004 and 2005.

Natural Mortality: Unchanged from last year, equal to those assumed in the assessment.
Proportion of $\mathbf{M}$ and $\mathbf{F}$ before spawning: Unchanged from last year at 0.67 .

### 2.7.3 Prediction for 2004 and management option tables for 2005

## Assumptions and Predictions for 2004

Due to the recent change in the fishery, and the low level of retrospective error in the most recent assessment, only options assuming Fstatus quo ( $\mathrm{F} 2004=\mathrm{F} 2003$ ) are presented. The partial fishing mortalities at $\mathrm{F}_{\text {status quo }}$ appear in tables 2.7.1.

## Management Option Tables for 2005

The EU-Norway agreement specifies fishing mortalities for juveniles ( $\mathrm{F}_{0-1}$ ) and for adults ( $\mathrm{F}_{2-6}$ ). With four fleets there are innumerable combinations of fleetwise fishing mortalities and catches that satisfy this constraint.

In each set, a range of fixed catches were assumed for fleets $C$ and $D(10000-50000 t$ in steps of 5000 t for fleet C and $2000-22000 t$ in steps of $2000 t$ for fleet D). For each combination of these, the catches by the fleets A and B were adjusted to give an $\mathrm{F} 0-1$ and an $\mathrm{F}_{2-6}$ at specified values ( 0.10 or 0.12 for $\mathrm{F}_{0-1}$ and 0.20 or 0.25 for $\mathrm{F}_{2-6}$ ).

The text table below is an overview of the options tables (Tables 2.7.2 a-c)

| Assumption for <br> 2004 | $\mathrm{F}_{0-1}$ <br> 2005 | $\mathrm{F}_{2-6}$ <br> 2005 | Catch fleet C <br> 2005 | Catch fleet D <br> 2005 | Table |
| :--- | :--- | :--- | :--- | :--- | :--- |
| $\mathrm{F}_{\text {status quo }}$ | 0.10 | 0.20 | $10-50000 \mathrm{t}$ | $2-20000 \mathrm{t}$ | 2.7 .3 a |
|  | 0.10 | 0.25 | $10-50000 \mathrm{t}$ | $2-20000 \mathrm{t}$ | 2.7 .3 b |
|  | 0.12 | 0.25 | $10-50000 \mathrm{t}$ | $2-20000 \mathrm{t}$ | 2.7 .3 c |

## All predictions are for North Sea autumn spawning herring only

In addition, an extract of Tables $2.7 .2 \mathrm{a}-\mathrm{c}$ containing a limited number of management options is presented as Table 2.7.3. This table also includes the option that $\mathrm{F}_{\text {status quo }}$ is continued in 2005.

All scenarios presented (Tables 2.7.2. a-c) indicate a continued increase in spawning biomass and in yield. This is mainly caused by the 1998 and 2000 year classes. The weak 2002 and 2003 year classes leads to comparatively low catches in the fleets exploiting mainly juveniles. The catches by the A fleet are estimated close to 500000 tonnes at $\mathrm{F}_{2-6}$ $=0.25$, while the catches by the $\mathrm{B}, \mathrm{C}$ and D fleets is a trade-off between these fleets, the sum of which will be approximately $60-100000$ tonnes with an $\mathrm{F}_{0-1}=0.12$.

### 2.7.4 Comments on the short-term projections

Making fleetwise predictions for 4 fleets that are more or less independent remains problematic, in particular when it comes to presenting results in a way that allows managers to overview the range of possible trade-offs between fleets.

It is also worth noticing that the realised $\mathrm{F}_{2-6}$ in the past have exceeded that intended when setting the TACs for many years. If managers wish to avoid exceeding the agreed limits, options with lower F-values may be preferable.

In a longer term perspective, the small year classes 2002 and 2003 will lead to reduced catches and SSB in the coming years (see Section 2.12).

The predictions presented here account for the delayed maturation of the large 2000 year class. To what extent the increased stock size will lead to slower growth and maturation in the future remains to be seen. There are some indications that this was the case when the stock was large prior to 1960. (ICES 1998)

The estimated impact of the juvenile fishery depends on the assumed value for natural mortality. It has not been investigated to what extent changes in natural mortality would affect the current advise, or if indeed such changes are taking place. However, some of the important predator stocks are currently in a poor condition.

### 2.8 The harvest rule for North Sea herring revisited

The management arrangement that was adopted in 1998 by EU and Norway has now been in effect for 6 years. The agreement is to set quotas according to a fishing mortality for adults (F2-6) at 0.25 and a fishing mortality for juveniles (F0-1) at 0.12, as long as the SSB is estimated to be above 1.3 million tonnes. At SSB below 1.3 million tonnes, the agreement was just to adapt 'the fishing mortality in the light of scientific estimates of the precise conditions then prevailing, to ensure rapid recovery of SSB to levels in excess of 1.3 million tonnes.'

Most of the time since then, the stock was in a rebuilding phase, the SSB being estimated below the trigger value of 1.3 million tonnes. In the rebuilding period, the parties decided on a year to year basis to have a fishing mortality on adults (F2-6) at 0.2 as a target, and to keep the fishing mortality for juveniles as low as at all possible. Thanks to strong regulations, the F0-1 was about 0.05 most of the time.

The agreement was to a large extent based on medium-term simulations made in 1997 (Patterson \& al 1997). Since this is 7 years ago, and the management regime as agreed only became effective recently, the WG found it appropriate to revisit the harvest rules with new simulations. Another incentive was the suggestion by the Methods WG
(ICES CM 2004/D:03) and the SGLTA (ICES CM 2004/ACFM:16) that the North Sea herring would be a good candidate for evaluation of harvest rules with software already existing.

The HCR was evaluated by applying it to a simulated population in a 10 years time perspective. This was done as a forward projection of the stock with given fishing mortalities and assumed natural mortalities, where the fishing mortalities were derived from the removal decided by the HCR. The HCR decides on either a fishing mortality or a catch according to the SSB resulting form the application of the rule. Errors in future assessments and in future implementation of the decided quotas were included as distributions.

The software used was STPR (Skagen, 1997a) for simulation of harvest rules in the medium-term and LTEQ (Skagen, 1997b) for long-term stochastic equilibria.

The model was run for two fleets, each characterised by its partial fishing mortalities at age. The first fleet ('Adult') corresponds to fleet A, while the other ('Juvenile') fleet corresponds to fleets B, C and D.

Recruitment: The stock-recruitment function to be used was scrutinised, since this is the most critical element for the risk associated with the management regime. The recruitments were modelled as $\mathrm{R}(\mathrm{y})=\mathrm{R}^{\prime}(\operatorname{SSB}(\mathrm{y}))^{*} \exp (\varepsilon(\mathrm{y}))$ where $\mathrm{R}^{\prime}(\mathrm{SSB}(\mathrm{y}))$ is a deterministic stock-recruit function and $\varepsilon(\mathrm{y})$ is a random number with a normal distribution.

Both a Beverton-Holt function and the 'Ockhams razor' - with a constant recruitment at SSB above a break point and a linear reduction below that level, were explored.

A spreadsheet was used to minimise the sum of squared log residuals of historical recruitments. With the Bever-ton-Holt function: $R=a * S S B /(b+S S B)$, the $a$-parameter became quite large: $83 * 10^{9}$, indicating that the recruitment would continue to increase with increasing SSB well beyond the range in the current set of stock-recruit pairs. The Study Group on Stock-Recruitment relationships for North Sea herring (ICES 1998) investigated stock and recruitment back to 1947. In the period prior to 1960 , when the spawning biomass at time was estimated at up to 5.3 million tonnes, most year classes were in the order of $30-60 * 10^{9}$, the exceptions being the 1956 and 1960 year classes, that were above $100^{*} 10^{9}$. From this experience, it does not seem likely that the shape of the Beverton-Holt curve gives a realistic representation of the recruitment at large SSB.

Estimating the level parameter in the Ockhams razor function:

$$
\begin{gathered}
\mathrm{R}=\mathrm{a} ; \quad \mathrm{SSB} \geq \mathrm{b} \\
R=a * S S B / b ; \quad S S B<b
\end{gathered}
$$

at various values for the break-point $b$ gave slightly increased estimates at increasing values for the break-point. The best fit was obtained with a break point of $b=609000$ tonnes, giving a plateau level of $a=52.6 * 10^{9}$. This fit is clearly better than with the Beverton-Holt function

When using the stock-recruitment relation in a prediction, it is mandatory that the error is independent of the SSB. In the model fits described above there were moderate correlations between residuals and SSB. Adding the constraint that the correlation be zero, increased the SSQ slightly, and reduced the level parameter in both models.

The text table below gives an overview of the explorations.

| Model | $a$-parameter*10 | SSQ | Correlation |  |
| :--- | :---: | :---: | :---: | :---: |
| B-H as (ICES 1998) | 61.99 | $b$-parameter | 15.34 | 0.05 |
| B-H: no constraints | 82.96 | $428^{*} 10^{6}$ | 14.74 | -0.08 |
| B-H: Corr $=0$ | 72.23 | $6594^{*} 10^{6}$ | 14.88 | 0 |
|  | $506^{6} 10^{6}$ |  |  |  |
| Ockham: <br> no constraints | 52.47 | 608 | 13.55 | -0.09 |
| Ockham: <br> Corr $=0$ | 49.34 | 537 | 13.70 | 0 |

Based on these explorations, the Ockhams razor function as derived with constraints on correlation (i.e. the last line in the table above) was used in the simulations.

Figure 2.8.1. shows a plot of cumulated probabilities of log recruitment residuals according to the distribution model used for medium and long-term simulations, versus cumulated probabilities of historic recruitment residuals (Q-Q-plot).

The STPR software assumes a log-normal distribution of the recruitments. The distribution was truncated to avoid values outside the range that has been recorded historically. Figure 2.8.2. shows the cumulated distribution of recruitments generated for year 10 by the STPR simulation programme, together with the cumulated distribution of historic recruitments. The shape of the two distributions diverge to some extent, but the arithmetic means are virtually identical.

Initial numbers: These were drawn randomly from a multivariate normal distribution of the logarithm of the numbers. The mean values and the variance-covariance matrix were obtained from the most recent ICA assessment.

Weights-at-age and maturities at age were drawn from historical values, by drawing years and use all weights and maturities at age for that year. For practical reasons, the same weights in the catch were used for both fleets.

The selection at age was as estimated by ICA for 2003, split on fleets according to the catches in 2003.

## Long-term equilibria

In the long-term, the 5-percentile of the SSB seems to follow a near linear relation between the fishing mortality as juveniles and as adults. This is shown for some SSB-levels in Figure 2.8.3. At a given level of the 5-percentile, the sum of F for the juvenile fleet, expressed as F0-1, and the F of the adult fleet, expressed as F2-6, is nearly constant, as shown in Figure 2.8.4. Some examples of this relation is shown in the text table below.

| Sum of F0-1 and F2-6 | 5 percentile of long-term distribution of <br> SSB |
| :---: | :--- |
| 0.55 | 800000 |
| 0.47 | 1000000 |
| 0.40 | 1300000 |

These results are in accordance with what has been found previously (Patterson \& al, 1997).

## Medium-term simulations with no error in assessment and implementation.

For these simulations, the fishing mortality for juveniles was kept at 0.12 and for adults at 0.25 . If this led to a predicted SSB for the next year below 1.3 million tonnes, the $F$ on juveniles was reduced to 0.05 and for adults to 0.2 . The effect of deviating from these standards was explored briefly, and the results are presented in Table 2.8.1

## Medium-term simulations with error in assessment and implementation.

As an example of the effect of overestimation of the stock abundance and overfishing of quotas, a similar set of simulations were made with the assumption that the assessment overestimated the stock with a factor of $10 \% \pm 20 \%$ (SD), assuming a normal distribution of the error. Likewise, a $20 \% \pm 20 \%$ (SD) overfishing of the quotas was assumed. The results of these runs are shown in Table 2.8.2.

The perceived SSB will be larger than the true SSB because of the overestimation of the stock.
Both a lower action level than 1.3 million tonnes, and a higher fishing mortality on either adults or juveniles leads to a risk that the stock in reality will be below 800000 tonnes higher than $5 \%$ in this example.

## Conclusions

The results from this study are quite in line with those that formed the background for the current regime (Patterson \& al, 1997). The current regime implies a low risk of undue reduction of the biomass. The impact of the level of juvenile fishing mortality is mostly to reduce the subsequent catch opportunities on the adults, although a high (e.g. 0.2) juvenile fishing mortality leads to some rise in the risk that SSB falls below the action point of 1.3 million tonnes. A modest increase in adult F is tolerable, but gives a relatively small gain in yield, while a larger increase leads to increased risk.

The performance of the management rule is strongly dependent on the precision of the assessment and the adherence to the quotas. In the example here, which may be realistic, there is a substantial risk that the action point is exceeded, and even the risk to the limit biomass of 800000 tonnes is noticeable. Reducing the target Fs has a beneficial effect. Hence, unless the assessments are very precise and the quotas are strictly adhered to, one should hesitate to increase the F-levels in the current rule.

## $2.9 \quad$ Precautionary reference points

In 2003, SGPRP (ICES 2003 ACFM:15) suggested to reduce the $\mathbf{B}_{\text {lim }}$ from the current 800000 tonnes to about 560000 tonnes, based on the results of the segmented regression analysis of the stock and recruitment data. Fitting an "Ockham Razor" stock-recruit function with non-linear minimisation of the SSQ of log residuals (section 2.8) suggests a break point at 537,000 tonnes. Although it is apparent that the recruitment historically has been at about the same level when the SSB was somewhat below 800000 tonnes as above, the HAWG decided not to propose any revision of the reference points at present for the following reasons:

- There is some doubt as to the validity of the calculation procedure used by the SGPRP
- The HAWG would prefer to consider all reference points together, rather than revising just $\mathbf{B}_{\text {lim }}$.

Moreover, there is a well functioning harvest control rule in place for this stock, and apart from $\mathbf{B}_{\text {lim }}$, the current reference points are derived from this HCR. The target F in the HCR was adopted by ACFM as the $\mathbf{F}_{\mathrm{pa}}$, while the trig-
ger point at which F should be reduced below the target is adopted as $\mathbf{B}_{\mathrm{pa}}$. Future revisions of the reference points should not trigger alterations in this HCR (see section 2.8).

### 2.10 Quality of the Assessment

### 2.10.1 Sensitivity of the assessment to sampling variability in the input data

The influence of sampling variability in the input data on the output of the assessment has been explored through the bootstrap analysis, documented in SGEHAP report. This was reported in detail in the 2003 Working Group report. All the analyses carried out by this method are conditional on the total catch in tonnes, the Working Group choice of fixed natural mortality and the choice of assessment method ICA (Patterson 1998, and Needle 2000) with predefined inverse variance weighting of the data. The model formulation and index weighting are described in Section 2.6.1. For this study eight different terminal years from 1994 to 2001 were tested and the addition of two years is not expected to alter the broad conclusions. It is intended to re-evaluate this work when a benchmark assessment is carried out. Figure 2.10.1 taken from the 2003 WG report shows the influence of sampling variability on each data source in the assessment. The results for the eight years are combined by expressing the output as the relative deviation from the mean of the set obtained from the assessments based on fixed value input data. This figure shows that the estimates of terminal SSB and $\mathrm{F}_{\text {adult }}$ are the most sensitive to the precision of the Acoustic survey. The MIK, Larvae and IBTS surveys form a second group with precision influencing the results to a lesser extent. The variability due to sampling for estimates of catch in numbers-at-age, the weights-at-age in the stock and the fraction mature form a third group of factors, and these have the least influence. SSB does vary a little due to sampling errors in mean weights and maturity but F is almost independent of these parameters. The results show that the estimates of TAC were almost equal dependent on MIK, IBTS and Acoustic surveys, with some influence from catch-at-age and MLAI but almost no influence from maturity or mean weights in the stock.

All the data combined suggest that the precision of the input data contributes to a range of outputs between 0.75 to 1.21 times the TAC, although there are about $1 \%$ of outlying values with greater deviation.

### 2.10.2 Weighing of indices in the assessment

The index weighting in the ICA assessment is given in section 2.6 As can be seen in Figure 2.10.1 the relatively high weights on catch ( $3.1 \& 2.6$ for $2 \& 3$-ring herring respectively) do not make the assessment overly dependent on measurement variability in the catch. While the spatial variability of growth and fraction mature for North Sea herring is considerable (Figure 2.3.1.4), the influence of the sampling variability in the main management criteria for the stock is small and its influence on the TAC is minimal.

Two XSA assessments are presented in section 2.6. The weighting of indices in the current assessment is compared to weighting in these two XSA assessments and an adaptive assessment using inverse residual weighting within ICA in Table 2.10.1. Both XSA assessments and the ICA adaptive assessment change weighting within the model. The weighting is taken directly from the model output tables. It is difficult to compare these values directly. In order to make comparison easier the weighting in each assessment have been normalised to give the total weight to the acoustic survey a value of five, which is close to the value for the three adaptive assessments.

The common features to weighting for these assessments are:

- The current assessment (ICA fixed weight) and both XSA assessment give a weighting to the Acoustic survey at about three times the IBTS index.
- All the assessments give declining weight with age on the IBTS survey

The differences between the assessments are:

- Adaptive weighting gives much lower weight to the MIK index
- Adaptive weighting gives more weight to the older ages in the acoustic survey. (ICA adaptive has a flat profile of weighting by age, XSA weights rise with age.)

These specific weighting issues were addressed in SGEHAP.

- The high weighting on the MIK was examined; although the survey is known to be rather precise there was concern that the use of uniform mortality through the year at age 0 -ring might be inappropriate in the model and thus reduced weighing might be a better solution. Nevertheless following tests it was found that reduced weighting gave more variable results and high weighting on the MIK gave a more stable assessment.
- For the older ages in the acoustic survey it was found that allowing flexibility in weighting gave more weight to more variable data at older ages in the acoustic survey and by forcing reduced weights here the assessment became
less sensitive to known increased variability at these ages. It was thought that the model fit was too flexible at these ages and that this flexibility allowed 'over fitting' resulting in variable output.

### 2.10.3 Update of catch numbers and mean weights-at-age in the catch

SGREDNOSE worked in 2003 to provide updated catch (see Section 1.4.1) and delivered a completely revised data set for HAWG in 2004. There have now been revisions to the catch data and weights-at-age in the catch covering the year 1995 to 2001. Only in 1995 and 1996 did these changes in catch exceed $10 \%$ and the influence of the changes on the assessment was found to be negligible. The change in terminal year was very small ( $<0.1 \%$ ) The biggest change was in $1993(1.5 \%$ in SSB and $-2 \%$ in F$)$ and $1995(-3 \%$ in SSB and $+3 \%$ in F$)$.

### 2.10.4 Sensitivity to measured maturity

The 2003 acoustic survey estimate of the fraction of 2-ring herring that spawned in 2003 was $43 \%$ of the year class. This is the lowest fraction mature in the recent history of the stock (84-2002) and compares with values of $77 \%$ and $86 \%$ for the years 2001 and 2002 respectively. The source of the data and comparison with growth parameters for the year class are discussed in section 2.4.2. The precision of this measure was investigated through a simple bootstrap of the acoustic survey data. The 5 and 95 percentiles on measured fraction mature were $39 \%$ and $61 \%$ respectively, these percentiles ignore spatial autocorrelation in the data and the true intervals are probably closer to the mean. The data therefore support the view that there is a significant decrease in fraction mature which is probably due to slow growth of the very large 2000 year class. The implications for the assessment is that the SSB is estimated as lower than would otherwise be the case. The effect was evaluated by comparing of growth and maturity data from the acoustic survey in previous years. This shows that had all the 2 -ring herring both grown and matured at a rate equal to the average of the previous 3 years ( $76 \%$ mature) this would have resulted in an increase in SSB of $27 \%$ or 2.2 Mt .

### 2.10.5 Use of tuning indices in the 2004 assessment

In this year's surveys, Acoustic, IBTS and MLAI surveys display a substantial upward trend in SSB, from 2002 to 2003, the MLAI gives the highest value. All three indices lead to an unequivocal indication of rising biomass when used in the assessment on their own along with the catch data. The IBTS indicates a reduction in SSB in 2004 as the low 2001 year class fails to replenish the stock. ICA provides a variance/covariance method to bootstrap parameters estimated in the assessment. Five scenarios have been examined, the four main indices (Acoustic survey, IBTS, MIK and MLAI) and the final assessment. Figure 2.10 .3 shows 100 bootstrap estimates for each scenario. The spread of terminal F and SSB is consistent among indices and with the combined assessment, with the exception of the assessment using the 0 -ring MIK index which gives most of the high estimates of biomass. As this index provides estimates of only 0 ring recruits it is not particularly informative for the current state of the stock. From Figure 2.10.3 it can be seen that there is little difference in perception of SSB when using each index separately (excepting the MIK) or when they are combined in the final assessment.

### 2.10.6 Comparison with 2003 assessment and projection

The 2004 assessment is in extremely good agreement with last years assessment with the exception of reduced fraction mature of the 2000 year class. See table below.

| Assessment year | SSB in 2002 | F2-6 in 2002 | SSB in 2003 | F in 2003 |
| :--- | :--- | :--- | :--- | :--- |
| $\mathbf{2 0 0 3}$ | $\mathbf{1 . 5 9 ~ M ~ t ~}$ | $\mathbf{0 . 2 4}$ | Projected 2.17 Mt | Projected 0.25 |
| $\mathbf{2 0 0 4}$ | $\mathbf{1 . 5 8} \mathbf{~ M ~ t ~}$ | $\mathbf{0 . 2 4}$ | Assessed 1.74 Mt | Assessed 0.24 |
|  |  |  | ***Corrected for low |  |
|  |  |  | maturity 2.22 Mt |  |

***As shown in the above table and discussed in detail in Section 2.4 due to the slow growth and late maturing the SSB of the 2000 year class has been estimates as lower. If the 2000 year class had developed in the same manner as the previous 3 year classes (as assumed in the projections) the current SSB would have been 2.22 Mt .

### 2.10.7 Uncertainty in the 2004 assessment

The current estimate of SSB is dominated by the highly abundant 2 and 3-ringers in 2003 and results from a compromise between the various sources of information.

The 2000 year class ( 90,000 million) is thought to be third highest in the history of the stock, at $84 \%$ above geometric mean recruitment (1983-2000), and larger that the 1998 year class ( 71,000 million) which has provided the recent large rise in the SSB. Estimates of incoming year classes are still uncertain, the 2001 year class (2-ring herring in 2004) have been estimated by the MIK at 0 -ring, IBTS at $2 \& 1$ and Acoustic at 1 -ring; these four estimates are all in good agreement ( 54,000 million $12 \%$ above geometric mean) with $\log$ residuals less than $\pm 0.30$. The 2002 year class ( $1-$ ring in 2004) is estimated by the MIK and the IBTS which are in very good agreement and is thought to be low at about
$43 \%$ of geometric mean recruitment (this was estimated at $40 \%$ of geometric mean recruitment in 2003). The 2003 year class is estimated only by the MIK and is even lower at $38 \%$ of geometric mean recruitment.

### 2.10.8 Comparison of ICA with XSA

For comparison two XSA runs are presented in Section 2.6.1.4. To have similar assumptions to ICA XSA is run with weak shrinkage, and the full data set for all the age based surveys used to obtain the survey catchability (Q). A second higher shrinkage XSA run has also been carried out for comparison. There are only small differences in the results for these three assessment methods (Figure 2.10.2). Compared to this years final assessment the weakly shrunk XSA assessment shows less than $6 \%$ reduction in SSB. When shrinkage is increased in XSA there is a slightly larger reduction in SSB in the terminal year and a small rise in terminal F. The perception from all these assessments is of a lightly exploited stock with SSB rising from around $800,000 \mathrm{t}$ in year 1999 to between 1.55 to 1.75 Million tonnes (Mt) in 2004.

### 2.10.9 Comparison with earlier assessments

As indicated above the current assessment agrees very closely with the 2003 assessment, except for the fraction mature in the 2000 year class.

An historic retrospective of assessments by sequential working groups is presented in Figure 2.10.4. Values for retrospective bias and standard error (Jónsson and Hjörleifsson 2000) are presented in the figures. This analysis suggests an average bias of about 0.18 for SSB and -0.19 for $\mathrm{F}_{2-6}$ for the period 1992 to 2003. The magnitude of the revision seems to be different in different periods, it is less in the last four years (2000-2003) than for the years 1998 and 1999, and then improves again in 1996 and 1997. Comparison with the retrospective of this years assessment (analytic retrospective), presented in section 2.6, shows a similar pattern. Assessments in 1996 and 1997 are more similar to the current assessment than those in 1998 and 1999. It is thought this period of the assessment has been made more difficult due to the difficulties in modelling the change in the fishery from 1996 and 1997, following the changes in management advice. The even earlier retrospective revision seen at the beginning of the time-series from 1992 to 1995 is the poorest and is probably due to changing data series and methods through this period. It is hoped that currently the assessments can be more stable, because the WG has currently adopted consistent use of a single model (ICA) and has available data of a consistent quality. However, for the future it remains to be seen if this improvement is sustained. For example if fishing practices change again in response to stock size and management changes the assessment may again become more unstable.

### 2.10.10 Predictions

The short-term prediction method was substantially modified in 2002. Following the review by SGEHAP (ICES 2001/ACFM:22), which recommended that a simple multi-fleet method would be preferable, the complex split-factor method used for a number of years prior to 2002 has not been used since. The multi-fleet, multi-option, deterministic short-term prediction programme (MFSP) was accepted by ACFM and was developed further last year. It is intended to continue to use this programme in the future. Last year's short-term prediction suggested that the North Sea autumnspawning herring stock SSB in 2003 would be around 2.1 Mt . This compares well with this year's estimate of the 2003 SSB which is 2.2 Mt , once the low maturation was taken into account. This demonstrates that the current prediction procedure for stock numbers is working well. The Working Group has included prediction of low maturation into projections for 2005 and expects to monitor growth and maturation of North Sea herring carefully in the future and when deemed necessary will include these changes in predictions in the future.

### 2.11 Herring in Division IVc and VIId (Downs Herring).

Over many years the working group has attempted to assess the contribution of winter spawning Downs herring to the overall population of North Sea herring. There is a separate TAC for herring in areas IVc and VIId as part of the total North Sea TAC. The TAC for IVc and VIId in 2004 was increased from 59,542 tonnes to 66,098 tonnes, the highest TAC since 1986 (Table 2.11.1). This was despite the ACFM advice in 2002:
"..TACs for this component have been significantly exceeded in all years. The TAC for this component was increased in 2002 (to 42,000 t) following the advice of ICES in 2001. However, the strong increase in SSB in the North Sea stock in 2001 is not mirrored in the Downs component, and therefore the TAC for Downs herring should not increase."

The 2003 ACFM advice was:
> "that it should not increase faster than the TAC for the North Sea as a whole. ... a share of 11\% on the total North Sea TAC (average share 1989-2002) would be an appropriate guide to distributing the harvesting among Downs herring"

A range of methods have been used by the WG in recent years to determine the proportion of Downs herring (relative to the total North Sea) and trend in population size of Downs herring. These are the proportion of 1-ringer juveniles that are less than 13 cm in length in the IBTS 1Q survey, the Larvae Abundance Index (LAI) for the IVc and VIId area and the short time-series of MIK surveys in the region. In addition, this year the larvae data were used to construct a primitive Larvae Production Estimate (LPE) with assumed growth of 0.25 mm per day and a daily mortality rate of 0.1 . None of these methods address what proportion of F occurs outside VIId, during the summer fishery on mixed feeding aggregations in the North Sea.

All of the indices show relatively high estimates for the current year except for the MIK index. The larvae are generally considered to reflect the spawning potential in the area (i.e. the component's SSB) while the IBTS and MIK indices reflect year class strengths (Figures 2.11.1-3). The recent value in the index of small ( $<13 \mathrm{~cm}$ ) 1-ringer fish from the IBTS Q1 survey is high, suggesting a good recruitment coming from the 2002-2003 year class (Figure 2.11.1). The proportion in the catch is also high suggesting that the year class strength relative to the other North Sea herring components is relatively higher than last year (Figure 2.11.1). The MIK survey suggests that the 2003 year class will be poor (Figure 2.11.2). Both the larvae abundance and larvae production index suggest that the spawning potential of the component has been increasing since 1994 (Figure 2.11.3). However none of these indices provide information on the exploitation of the component.

New information from the HERGEN project (genetics and otolith microstructure analysis) supports the previous hypothesis that the juveniles of Downs herring are found in IIIa..

There is a vital need for a reassessment of the methods used to investigate the size of the Downs herring stock component. Section 1.4.6 of this report documents new projects that are aimed at addressing the provision of management advice specifically for the Downs herring. To conclude, the current state of the component is unknown. The WG's understanding of the substock dynamics is unlikely to improve until further examination of the existing timeseries of surveys takes place, in light of both alternative assessment methods, and a greater knowledge the ecology of Downs herring.

### 2.12 Management Considerations

Based on the most recent estimates of SSB and fishing mortality, the North Sea autumn spawning herring stock is considered to be within precautionary limits and harvested sustainably. SSB in 2003 was estimated at 1.74 million t and is expected to increase to 2.1 million tonnes in 2004, which is above the $\mathbf{B}_{\mathrm{pa}}$ of 1.3 million t . SSB has increased gradually since the low stock size in the mid-1990s, in response to reduced catches, strong recruitment and management measures that reduced exploitation both on juveniles and adults. In 1996 the fishing mortality for the adult part of the stock was reduced to 0.4 . It has further decreased in subsequent years, being close to 0.25 in 2002 and 2003. For juveniles the fishing mortality remained below 0.1 since 1996 .

The EU-Norway Management agreement was updated in December 2001, the relevant parts of the text are included here for reference:-

1. Every effort shall be made to maintain a level of Spawning Stock Biomass (SSB) greater than the Minimum Biological Acceptable Level (MBAL) of 800,000 tonnes.
2. A medium-term management strategy, by which annual quotas shall be set for the directed fishery and for bycatches in other fisheries as defined by ICES, reflecting a fishing mortality rate of 0.25 for 2 -ringers and older and 0.12 for 0-1-ringers, shall be implemented.
3. Should the SSB fall below a reference point of 1.3 million tonnes, the fishing mortality rates referred under paragraph 2, will be adapted in the light of scientific estimates of the precise conditions then prevailing, to ensure rapid recovery of SSB to levels in excess of 1.3 million tonnes.

The recovery plan referred to above may, inter alia, include additional limitations on effort in the form of special licensing of vessels, restrictions on fishing days, closing of areas and/or seasons, special reporting requirements or other appropriate control measures.
4. By-catches of herring may only be landed in ports where adequate sampling schemes to effectively monitor the landings have been set up. All catches landed shall be deducted from the respective quotas set, and the fisheries shall be stopped immediately in the event that the quotas are exhausted.
5. The allocation of the TAC for the directed fishery for herring shall be $29 \%$ to Norway and $71 \%$ to the Community. The by-catch quota for herring shall be allocated to the Community.
6. The parties shall, if appropriate, consult and adjust management measures and strategies on the basis of any new advice provided by ICES including that from the assessment of the abundance of the most recent year class.
7. A review of this arrangement shall take place no later than 31 December 2004.
8. This arrangement entered into force on 1 January 2002.

Landings of adult herring in recent years have consistently exceeded the agreed TAC, mainly due to unallocated catches and catches misreported into and out of the North Sea (see section 2.1).

The 1998 year class and the 2000 year class appear to be very strong in all the surveys and in the catches. They will comprise $39 \%$ and $17 \%$ of SSB in 2004 respectively. In the past large year classes have tended to have a lower maturation rate than the long-term average. These signals have not been detected for the 1998 year class as the proportion mature appears to be above average. However, the 2000 year class has been seen to exhibit a reduced growth and maturation in 2003. As this is expected to continue in 2004, the reduction has been taken into account for the short-term projections.

The ICES advice for 2004 is based on the projected SSB in 2005 being above 1.3 million t . SSB in 2005 depends on the fisheries in 2004 and that part in 2005 that takes place before spawning. About $2 / 3$ of the total mortality is expected to be realised before spawning each year. The increase in SSB projected for 2004 depends on the incoming 2000 and 2001 year classes. Observations from different surveys indicate that the first of these is very strong and the second near average. Generally, the surveys provide more reliable indications of year class strength than catches of juveniles do. Initial estimates of the 2002 and 2003 year classes suggest that they are both the lowest observed in the last 23 years. This is expected to reduce the catch of juvenile herring in the B-C -and D-fleets in 2004. Medium-term projections maintaining Fstatus quo (which is very close to EU Norway agreement of F adult $=0.25$ but with lower exploitation on juveniles) demonstrate that it will be necessary to reduce catches for the A-fleet in 2006 and 2007. This reduction will be about $12 \%$ by 2007. Increase in exploitation of juveniles (to $F=0.12$ ) or adults above this level may require greater reduction

Discards were so far considered to be relatively unproblematic in the North Sea herring fishery (less than $5 \%$ of the total catch, based on observer sampling programs). In 2002 for the first time, onboard sampling observed substantial discards of herring in the mackerel fishery in the $3^{\text {rd }}$ and $4^{\text {th }}$ quarter in Div. IVa(W). The discard figure used for the assessment was $17,000 \mathrm{t}$. For 2003, discarding was estimated at $4,100 \mathrm{t}$. These estimates come from rather limited reports from discard programs.

This stock complex also includes Downs herring (herring in Divisions IVc and VIId), which has shown independent trends in exploitation rate and recruitment, but cannot be assessed separately. This year the Working Group concludes that the current state of the component is unknown. The WG's understanding of the component's dynamics is unlikely to improve until further examination of catch and the existing time-series of surveys takes place. Both, alternative assessment methods have to be explored, and a greater knowledge the ecology of Downs herring is needed. The Downs fishery is concentrated on the spawning aggregations in a restricted area, which makes this stock component particularly vulnerable to excessive fishing pressure.

The EU splits its share of the total North Sea herring TAC (Subarea IV and Division VIId) into TACs for Divisions IVa+IVb and for Divisions IVc+VIId (Downs herring). In response to ICES advice in May 1996, the IVc+VIId TAC was reduced by $50 \%$ in line with reductions for the whole North Sea. The TAC for Downs herring was reduced to $25,000 \mathrm{t}$ and remained there until 2001. The catches for this component have significantly exceeded the sub-TACs in all years since 1989. The sub-TAC was increased in 2003 (to 42,673 t) following the advice of ICES in 2001. In 2003 and 2004, it was increased first to $59,542 \mathrm{t}$ and then to $66,098 \mathrm{t}$ against the advice of ICES. The 2003 ACFM advice was "that it should not increase faster than the TAC for the North Sea as a whole. ... [A] share of $11 \%$ on the total North Sea TAC (average share 1989-2002) would be an appropriate guide to distributing the harvesting among Downs herring" The current sub-TAC for Downs herring is 1.6 times the long-term annual TAC of the component, whereas the North Sea TAC is 1.2 times the long-term TAC. It has long been argued that due to the different characteristics of the Down component (Cushing and Bridger, 1966; Burd, 1985) it is more susceptible to recruitment over fishing. Hence the working group is concerned that until better evidence is available, relative exploitation on this component should not rise above the long-term mean proportion for the area.

Table 2.1.1 HERRING caught in the North Sea (Subarea IV and Division VIId).
Catch in tonnes by country, 1994-2003. These figures do not in all cases correspond to the official statistics and cannot be used for management purposes.

## Preliminary.

4 Catches of Norwegian spring spawners removed (taken under a separate TAC).
5 Landings from the Thames estuary area are included in the North Sea catch figure for UK (England).
7 Including any by-catches in the industrial fishery
9 Figures verified and altered if needed in 2003 by SG Rednose (ICES 2003/ACFM:10)
10 Figure altered in 2001
11 Caught in the whole North Sea, partly included in the catch figure for The Netherlands
12 may include misreported catch from VIaN and discards
13 These catches (including some local fjord-type Spring Spawners) are taken by Norway under a separate quota south of $62^{\circ} \mathrm{N}$ and are not included in the Norwegian North Sea catch figure for this area.
14 Figure altered in 2004

## Preliminary

Landings from the Thames estuary area are included in the North Sea catch figure for UK (England).
Discards partly included in unallocated
May include misreported catch and discards.
Figures verified and altered if needed in 2003 by SG Rednose (ICES 2003/ACFM:10)
Figure altered in 2002 (was 7851 t higher before)
Thames/Blackwater herring landings: 107 t , others included in the catch figure for The Netherlands
Figure altered in 2004
Table 2.1.6 ("The Wonderful Table"): HERRING in Sub-area IV, Division VIId and Division IIIa. Figures in thousand tonnes.

 resolved intersessionally.

Table 2.2.1 North Sea Autumn Spawning Herring (NSAS), and Western Baltic Spring Spawners (WBSS) caught
in the North Sea 2003. Catch in numbers (millions) at age (CANUM), by quarter and division

Table 2.2.12 Sampling of commercial landings of Herring in the North Sea (Div. IV and VIId) in 2003 by quarter. Sampled catch means the proportion of the reported catch to which sampling was applied. It is limited to $100 \%$ but might exceed the official landings due to sampling of discards, unallocated and misreported catches. It is not possible to judge the quality of the sampling by this figure alone. Note that only one nation sampled their by-catches in the industrial fishery (Denmark, fleet B). Metiers are each reported combination of nation/fleet/area/quarter.

| Country $\quad$ (fleet) | Quarter | No of metiers | Metiers sampled | Sampled Catch \% | Official Catch | No. of samples samples | No. fish aged | No. fish measured | >1 sample per 1 kt catch |

| Total | 40700.1 | 4402.1 |  |  |  |

North Sea autumn spawners, estimates of (millions) at age from acoustic surveys, and SSB (thousands of tonnes) 1984-2003. For 1984-1986 the estimates are the sum of those from the Division IVa summer survey, the Division IVb autumn survey, and the Divisions IVc, VIId winter survey. The 1987 to 2000 estimates are from the summer survey in Divisions IVa,b, and IIIa excluding estimates of Division IIIa/Baltic spring spawners. For 1999 \& 2000 the Kattegat was
 proportion adult. The earlier surveys were revised in March 2002 following recent reorganisation of archive, removal of a $9 \%$ calibration error on Scottish survey 1999-2000. In 2003 the area was extended to include part of area IVc and provide better coverage for sprat, the increase in biomass due to this change in area was negligible at $0.05 \%$.

Table 2.3.2.5 Time-series of the Multiplicative Larval Abundance Index (MLAI). The original MLAI is given in the second column. MLAI ${ }_{\text {plus }}$ is the sum of the MLAI and the value of the reference area (Orkney/Shetlands, $1^{\text {st }}-15^{\text {th }}$ September 1972). This estimate is then unlogged (eMLAI) and divided by $100\left(\mathrm{MLAI}_{\text {assess }}\right)$. The $\mathrm{MLAI}_{\text {assess }}$ describes the time-series that is used in the assessment.

Reference Value: 6.83349

| Year | MLAI | MLAI $_{\text {plus }}$ | eMLAI | MLAI $_{\text {assess }}$ |

Table 2.3.3.4 North Sea herring. Density and abundance estimates of 0-ringers caught in February during the IBTS. Values given for year classes by areas are density estimates in numbers per square metre. Total abundance is found by multiplying density by area and summing up.

| Area | North <br> west | North <br> east | Central <br> west | Central <br> east | South <br> west | South <br> east | Division <br> IIIa | South- <br> ern <br> Bight | 0-ringer <br> abundance |  |
| :--- | ---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | ---: | ---: |
| Area m ${ }^{2} \times 10^{9}$ | 83 | 34 | 86 | 102 | 37 | 93 | 31 | 31 | no. in $10^{9}$ |  |

Table 2.6.1.3 North Sea herring. Model settings for XSA with low shrinkage of F (=2.0). Age=ringer.

```
Catch data for 44 years. 1960 to 2003. Ages 0 to 9.
\begin{tabular}{llcrrrr} 
Fleet & First & Last & First & Last & Alpha \\
Beta & & year & year & age & age & \\
Acoustic survey 2-9+ & 1989 & 2003 & 1 & 8 & .54 & .56 \\
IBTS: 1-5+ wr & 1979 & 2003 & 1 & 5 & .08 & .17 \\
MIK 0-wr & 1977 & 2003 & 0 & 0 & .08 & .17
\end{tabular}
Time-series weights :
            Tapered time weighting not applied
Catchability analysis :
    Catchability dependent on stock size for ages < 2
                Regression type = C
                Minimum of 5 points used for regression
                Survivor estimates shrunk to the population mean for ages <
2
    Catchability independent of age for ages >= 4
Terminal population estimation :
    Survivor estimates shrunk towards the mean F
    of the final 5 years or the 1 oldest ages.
    S.E. of the mean to which the estimates are shrunk = 2.000
    Minimum standard error for population
    estimates derived from each fleet = .300
    Prior weighting not applied
Tuning converged after 25 iterations
```

No of years for separable analysis : 5
Age range in the analysis : 0 . . . 9
Year range in the analysis : 1960 . . . 2003
Number of indices of SSB : 1
Number of age-structured indices : 3
Stock-recruit relationship to be fitted.
Parameters to estimate : 45
Number of observations : 388
Conventional single selection vector model to be fitted.
Survey weighting to be Manual (recommended) or Iterative (M/I) ?-->M
Enter weight for MLAI--> 0.650000000000000
Enter weight for Acoustic survey 2-9+ wr at age 1--> 0.740000000000000
Enter weight for Acoustic survey 2-9+ wr at age 2--> 0.750000000000000
Enter weight for Acoustic survey 2-9+ wr at age 3--> 0.640000000000000
Enter weight for Acoustic survey 2-9+ wr at age 4--> 0.270000000000000
Enter weight for Acoustic survey 2-9+ wr at age 5--> 0.140000000000000
Enter weight for Acoustic survey 2-9+ wr at age 6--> 0.130000000000000
Enter weight for Acoustic survey 2-9+ wr at age 7--> 0.120000000000000
Enter weight for Acoustic survey 2-9+ wr at age 8--> $7.0000000000000007 \mathrm{E}-02$
Enter weight for Acoustic survey 2-9+ wr at age 9--> $7.0000000000000007 \mathrm{E}-02$
Enter weight for IBTS: 1-5+ wr at age 1--> 0.670000000000000
Enter weight for IBTS: 1-5+ wr at age 2--> 0.240000000000000
Enter weight for IBTS: 1-5+ wr at age 3--> 5.9999999999999998E-02
Enter weight for IBTS: 1-5+ wr at age 4--> $2.9999999999999999 \mathrm{E}-02$
Enter weight for IBTS: 1-5+ wr at age 5--> 2.9999999999999999E-02
Enter weight for MIK 0-wr at age 0--> 2.050000000000000
Enter weight for stock-recruit model--> 0.100000000000000
Enter estimates of the extent to which errors in the age-structured indices are corre-
lated across ages. This can be in the range 0 (independence) 1 (correlated errors).
Enter value for Acoustic survey 2-9+ wr--> $0.0000000000000000 \mathrm{E}+000$
Enter value for IBTS: 1-5+ wr--> $0.0000000000000000 \mathrm{E}+000$
Enter value for MIK 0-wr--> $0.0000000000000000 \mathrm{E}+000$
Do you want to shrink the final fishing mortality (Y/N) ?-->N
Seeking solution. Please wait.

NOTE: North Sea herring (autumn spawners) are 0-ringers the year after they are spawned

```
No of years for separable analysis : 5
Age range in the analysis : 0 . . . 9 age=rings
Year range in the analysis : 1960 . . . }200
Number of indices of SSB : 1
Number of age-structured indices : 3
Stock-recruit relationship to be fitted.
Parameters to estimate : 45
Number of observations : 388
```

Conventional single selection vector model to be fitted.

Table 2.6.2.4 North Sea herring. Model fit parameters, residuals and diagnostics.

Table 2.6.2.4. cont. North Sea herring.

Table 2.7.2.c
Short-term prediction with $\mathrm{FO}-1=0.12$ and $\mathrm{F} 2-6=0.25$
North sea herring 2004
Input data from: input
Results for the intermediate year 2004
with the folllowing constraints:
Fleet 1 F constraint: 0.2326
Fleet 2 F constraint: 0.0174
Fleet 3 F constraint: 0.0071
Fleet 4 F constraint: 0.0124

| F-values by fleet | and | total |  |
| :---: | :---: | :---: | ---: |
| F1 | F2 | F3 | F4 |
| 0.233 | 0.017 | 0.007 | 0.012 |

$\begin{array}{rrr}\text { F } 0-1 & F & 2-6 \\ 0.039 & 0.242\end{array}$
Catches by fleet

Results for the prediction year 2005
with the following types of constraints:
Fleet 1 Screen for total Fs
Fleet 2 Screen for total Fs
Fleet 3 Catch constraint
Fleet 4 Catch constraint

## 3 Herring in Division IIIa and Subdivisions 22-24

### 3.1 The Fishery

### 3.1. $\quad$ ACFM advice and management applicable to 2003 and 2004

At the ACFM (May) meeting in 2003, it was stated that the status of the stock is unknown relative to safe biological limits, because reference points have not been determined. Although the assessment is uncertain SSB has been slightly increasing over the last four years. Fishing mortality is uncertain, but estimates for 2002 are 0.45 for adults and 0.17 for juveniles ( 0 - and 1-ringers), which is greater than $\mathbf{F}_{\text {max }}$. The incoming 2002 year class seems to be above average.

ACFM recommended that the fishing mortality should be reduced to less than $\mathbf{F}_{\max }(0.37)$ corresponding to catches in 2004 less than $92,000 \mathrm{t}$. According to the recent geographic distribution of catches, approximately half of the total catches should be taken from Subdivisions 22-24.

The EU and Norway agreement on a herring TACs set for 2004 was $70,000 \mathrm{t}$ in Division IIIa for the human consumption fleet and a by-catch ceiling of $21,000 \mathrm{t}$ to be taken in the small mesh fishery.

As in previous years the International Baltic Sea Fishery Commission (IBSFC) no special TAC for 2003 was set on the Western Baltic area the stock component. For the Baltic there was for 2002 a TAC of $200,000 \mathrm{t}$ for the SDs $22-$ 29 South and 32. The TAC for 2004 increased to $171,350 \mathrm{t}$ compared to $143,349 \mathrm{t}$ for the same area in 2003.

### 3.1.2 Catches in 2003

Herring caught in Division IIIa are a mixture of North Sea autumn spawners (NSAS) and Baltic spring spawning herring (WBSS) in the eastern part of the North Sea, Skagerrak, Kattegat and Subdivisions 22, 23 and 24 are considered to be one stock. This Section gives the landings of both North Sea autumn spawners and Baltic spring spawners, but the stock assessment applies only to the spring spawners.

Landings from 1985 to 2003 are given in Table 3.1.1. In 2003 the total landings decreased to $109,600 \mathrm{t}$ in Division IIIa and Subdivisions 22-24 compared with 2002 where the landings were $125,600 \mathrm{t}$, resulting in a landing figure for 2003 at the lowest level for the whole time-series. In 2003, 24,200 t were taken in the Kattegat, about $43,900 \mathrm{t}$ from the Skagerrak and 38,900 t from Subdivisions 22-24. These landings represent a decrease of 16,000 t compared to 2002 and $39,200 \mathrm{t}$ compared to 2001. The Danish national management regime for herring and sprat fishery in Subdivision 22 was changed in 2002. It should be noticed that the total landings for fishery in Skagerrak have been updated for 1995-2001 because of Norwegian misreporting of landings taken in the North Sea and reported to Skagerrak.

The German landings in 2003 were at the same level as in 2002. The overall change in the German fishing pattern was implemented in 2001. In former years the dominant part of herring was caught in the passive gears, gillnets and trapnets. The share of herring, which was caught by trawlers in the area off the Rügen Island coast up to the Arcona Sea (Subdivision 24), increased from $26 \%$ in 2001 to $63 \%$ in 2003. This significant change in fishing pattern was caused by the perspective of a new fish factory on Rügen Island. This factory expects to process $50,000 \mathrm{t}$ per year and started during autumn 2003.

In 2003 the landing data are calculated by fleet according to the fleet definitions used when setting TACs.
The fleet definitions used since 1998 are:

- Fleet C: directed fishery for herring in which trawlers (with 32 mm minimum mesh size) and purse seiners participate.
- Fleet D: All fisheries in which trawlers (with mesh sizes less than 32 mm ) and small purse seiners, fishing for sprat along the Swedish coast and in the Swedish fjords, participate. For most of the landings taken by this fleet, herring is landed as by-catch. Danish and Swedish by-catches of herring from the sprat fishery and the Norway pout and blue-whiting fisheries are listed under fleet D.
- Fleet F: Landings from Subdivisions 22-24. Most of the catches are taken in a directed fishery for herring and some as by-catch in a directed sprat fishery.

In the table below the landings are given for 2000 to 2003 in thousands of tonnes by fleet and quarter. The landings figures in the text table below are SOP figures. The 2000 and 2001 figures for fleet C were updated.

| Herring landings by <br> fleet ('000 t) |  | Div. IIIa |  | SD 22-24 |
| :--- | ---: | :--- | ---: | ---: | Div. IIIa+ SD 22-24

The landings from fleets C-F are SOP figures.

### 3.1.3 Catch in Numbers and Mean Weights-at-age

The level of sampling of the landings for human consumption and the industrial landings was generally acceptable in the Skagerrak and Kattegat and Subdivisions 22-24. Where sampling was missing in areas and quarters on national landings, sampling from either other nations or adjacent areas and quarters were used to estimate catch in numbers and mean weight-at-age (see Table 3.2.17).

Table 3.2.2 and Table 3.2.3 show the total catch (autumn and spring spawners) in numbers and mean weight-atage for herring by quarter and fleet landed from Skagerrak and Kattegat, respectively. The total numbers and mean weights-at-age for herring landed from the Kattegat, Skagerrak and Subdivisions 22-24 by fleets are shown in Table 3.2.10. Catch in numbers and mean weight has been updated/revised for 1995-2001 because of misreporting (see section 3.1.5)

Based on the proportions of spring- and autumn spawners (see Section 3.2.1 and Section 3.2.2) in the landings, number and mean weights by age and spawning stock are calculated. The total numbers and mean weight of the NSAS landed from Kattegat and Skagerrak by quarter and fleet is shown in Table 3.2.4 and 3.2.6. The total numbers and mean weight of the WBSS landed from Kattegat and Skagerrak by quarter and fleet are shown in Table 3.2.5 and 3.2.7.

The total numbers and mean weight of the NSAS by quarter and fleet landed from Division IIIa are shown in Table 3.2.8 and the WBSS in Table 3.2.9.

The total catch in numbers of WBSS in Division IIIa and the North Sea are shown in Tables 3.2.11 and 3.2.12 (see also Tables 2.2.1-2.2.5) The landings (SOP) of the WBSS taken in Division IIIa and the North Sea in 2003 were estimated to be about $37,000 \mathrm{t}$ (Table 3.2.15) compared to about $54,000 \mathrm{t}$ in 2002 and $48,000 \mathrm{t}$ in 2001. This decrease in landings (SOP) was mainly due to a decrease in the estimated number of spring spawners in Kattegat. Furthermore, there has been a decrease in total landings from fishery in Subdivisions 22-24 of 11,000 tonnes from 2002 to 2003. The landings (SOP) of NSAS in Division IIIa amounted to $26,000 \mathrm{t}$ compared to $48,000 \mathrm{t}$ in 2001 and $50,000 \mathrm{t}$ in 2000 (Table 3.2.13). The total catch in number and mean weight-at-age of WBSS in the North Sea, Division IIIa and in Subdivisions 22-24 for 1991-2003 are given in Tables 3.2.14 and 3.2.15.

### 3.1.4 Quality of Catch Data and Biological Sampling Data

Misreporting of fishing area still occurs. Some of the Danish landings of herring for human consumption reported in Division IIIa may have been taken in the adjacent waters of the North Sea. There is uncertainty about where the Danish landings for human consumption, reported from Division IIIa were actually taken. There is a high probability that these catches have been taken in the North Sea. Therefore, these catches have been transferred to the North Sea. The Norwegian landings reported as having been taken in Skagerrak for the period 1995 to 2003 may have been caught in the North Sea and have been transferred to the North Sea. Some landings, reported as taken in this triangle, (an area in the southern Kattegat, which is a part of the Baltic area: Gilleleje, DK - Kullen, S - Helsingborg, S - Helsingør, DK), may have been taken outside this area. These landings are listed under Kattegat.

No estimates of discards were available to the Working Group. The amount of discards for 2003 is regarded as being insignificant.

Sampling for species composition in the small-meshed fishery has been carried out as in previous years. Sampling in this section only refers to sampling for length, weight and age information.

The sampling intensity of the landings in 2003 was acceptable, the highest level ever and above the recommended level. Danish landings were sampled in the most important quarters for the Skagerrak, the Kattegat and for Subdivisions 22 and 24.

Tables 3.2.16 and 3.2.17 show the number of fish aged by country, area, fishery and quarter. The total landings from Division IIIa and Subdivisions 22-24 were 109,600 t from which 292 samples ( 1 sample per 370 t landed) were taken, 30,500 fish were measured and 14,800 aged. For comparison, for 2002 where $125,600 \mathrm{t}$ were landed from which 292 samples ( 1 sample per 450 t landed) were taken, 31,000 fish measured and 15,000 fish aged.

Although the overall sampling more than meets the recommended level of one sample per 1000 t landed per quarter, there is an unequal coverage of some areas and times of the year. In most cases quarter and fisheries have been sampled adequately, but still some quarters and fisheries have not been sampled. Comprehensive spatial and temporal sampling must be implemented in order to improve the overall sampling of landings.

There is an unknown effect of variability in the stock composition in Division IIIa due to uncertainty of the splitting factor between the NSAS and the WBSS. There is at present no information about the importance of local herring stocks in relation to the fisheries (i.e. the Kattegat autumn spawners and the Skagerrak winter spawners) and their possible influence on the stock assessment.

### 3.1.5 Revision of historical data

At the SGREDNOSE (ICES 2003/ACFM:10) revision of all herring landings figures for the period 1991 to 2002 were revised. New information indicated that the reported Norwegian landings from fishery in Subdivision IIIaN (Skagerrak) with a high probability have been taken in the North Sea. Therefore, all reported Norwegian landings from Subdivision IIIaN were transferred to the North Sea and the respectively catch figures, catch in numbers etc. have been updated for the period 1995-2001.

### 3.2 Biological Composition of the Catch

Catches of herring in the Kattegat, the Skagerrak and the Eastern part of the North Sea are taken from a mixture of two main spawning stocks mainly $2+$ ringers of the Western Baltic spring spawners and 0-2-ringers from the North Sea autumn spawners, including winter-spawning Downs herring (see stock annex). As in recent years the WG expanded the use of analysis of individual otolith microstructure for determination of spawning type in age-class stratified random sub-samples of herring in Division IIIa (see stock annex).

For the present year the otolith-based method has been exclusively applied for the Division IIIa split. For Subdivisions 22, 23 and 24 it was assumed that all individuals caught belong to the WBSS stock, even when otolith microstructure indicate occurrence of autumn spawners in the surveys or in samples of landings (see Appendix 3).

For the first time sampling levels in 2003 were high enough to allow the split to be applied to their respective spatial and temporal origin without reallocating between the landings and the surveys or between areas or quarters.

## 3.2. $1 \quad$ Spring-spawning herring in the North Sea

Catches from the transfer area within Subdivision IVa East and Division IVb are usually split by analyses of Norwegian samples (see Figure 2.2.2). For 1-ringers it was assumed that all fish were autumn spawners. For herring caught in the $2^{\text {nd }}$ quarter 2 -ringers, 3 -ringers, and 4+-ringers, mean vertebral counts in the transfer area were used (see stock annex). For the $3^{\text {rd }}$ quarter no Norwegian samples were available for landings from the transfer area and instead the otolithbased proportions from samples of Danish commercial landings from the same area were applied to the age distributions. The quarterly age distribution and mean weight-at-age in Subdivision IVa East was applied to the catches of the second and third quarters in the transfer area. The numbers of spring spawners by age were obtained by applying the estimated proportion by age. For the actual split see Section 2.2.2.

### 3.2.2 Autumn spawners in Division IIIa

For commercial landings in 2003 the split of the Swedish and Danish landings was conducted using the proportion by age in the combined samples of Swedish and Danish microstructure analyses. The estimation of the proportion spring and autumn spawners in the landings from Division IIIa was performed on the basis of totally 5847 (4857 Danish and 990 Swedish) otolith microstructure analyses in 2003. Data were disaggregated by area (Kattegat and Skagerrak), age group and quarter (1-4). The proportions and the analysed numbers are presented in Table 3.2.1.

In the acoustic survey in quarter 2 and 3 in Division IIIa 930 otoliths were analysed and applied for the split of this survey only. In the 2003 Division IIIa IBTS survey in the $3^{\text {rd }}$ quarter 375 otoliths were analysed and in the 2004 Division IIIa IBTS survey in the $1^{\text {st }}$ quarter 322 otoliths were analysed.

### 3.2.3 Autumn spawners in the fishery in Subdivisions 22 and 24

All herring found in subdivisions 22-24 are treated as Western Baltic spring spawners independent of spawning type from otolith micro-structure analysis (see Appendix 3).

### 3.2.4 Accuracy and precision in stock identification

Sub-samples of the 2003 Danish, Swedish and German otolith microstructure analyses were double checked by the same Danish expert reader for consistency in interpretation. An overall impression of excellent agreement among readers implies a potential high precision in the splits.

Preliminary results presented to the WG on mixed stock analysis exploiting genetic variation in herring from Division IIIa in 2003, show excellent agreement between assignments based on micro satellites and otolith microstructure (Bekkevold pers. commun. HERGEN QLRT - 2000 - 01370) indicating good accuracy of the split between North Sea and Western Baltic herring. The possibility of combining genetics and otolith analyses for a higher resolution will be explored in the near future.

### 3.3 Fishery-Independent Information

### 3.3.1 International Bottom Trawl Survey in Division IIIa

The survey indices were split into spring and autumn spawning components by microstructure analysis of otoliths (section 3.2) except for $20013^{\text {rd }}$ quarter and $20021^{\text {st }}$ quarter when vertebrae counting methods was used. The estimates of the abundance by age of the spring spawning component are presented in Table 3.3.1 and Table 3.3.2. The mean value for 1-ringers in $20041^{\text {st }}$ quarter is the lowest observed in the time-series.

### 3.3.2 Summer acoustic survey in Division IIIa

The echo integration survey from 30 June to 10 July 2003 covered the area in the Skagerrak and the Kattegat. Details of the survey are given in the 'Report of the Planning Group for Herring Surveys' (ICES 2004/G:05). The estimate spawning biomass of Western Baltic spring spawning herring in 2003 was about 104,000 tonnes, showing a substantial decrease compared with the previous year but similar to the 2001 estimate. The results from this survey are summarised in Table 3.3.3.

### 3.3.3 Autumn acoustic survey in western Baltic and the southern part of Division IIIa (Kattegat)

A joint German-Danish acoustic survey was carried out with R/V "SOLEA" between 30 September and 18 October 2003 in the Western Baltic. In 2003, it was planned to cover Subdivisions 21, 22, 23 and 24. A full survey report is given in the Report of the Planning Group for Herring Surveys (ICES CM 2004/G:05). The results for 2003 are presented in Table 3.3.4. The herring stock was estimated to be about 156,000 tonnes in Subdivisions 22-24 (Table 3.3.4). This is comparable to the last year estimates. Young herring dominated the abundance estimates.

### 3.3.4 Larvae surveys

The series from 1992 to 2003, shows strong correlations between the index derived from the larvae surveys and the abundance of recruits in the acoustic survey of Subdivisions 22-24 (Klenz, 2004). The old bottom trawl series using herring gear, which ended in 2001, also showed a significant correlation with 0 group abundance in Subdivision 24. There is a highly significant correlation with the index derived from the larvae surveys and the estimate of 0 group abundance in the current stock assessment. The estimated numbers of larvae for the period 1977 to 2003 are summarised in Table 3.3.5. The 2003 estimate of the larvae index is very similar to the previous year estimate and close to the 1998-1999 values.

### 3.4 Mean weights and Maturity-at-age in the Stock

Mean weights-at-age in the catch in the $1^{\text {st }}$ quarter were used as stock weights (Table 3.2.11). Ongoing work on updating maturity-at-age data was presented (WD Gröhsler \& Müller). The data coverage is still too sparse to allow using annual values, however international collaboration in this area may result in a different perception of SSB in the future, once new estimates replace the current mean values. The maturity ogive was assumed constant between years. The same maturity ogive was used as in the HAWG 2003:

| W-rings | 0 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | $8+$ |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| Maturity | 0.00 | 0.00 | 0.20 | 0.75 | 0.90 | 1.00 | 1.00 | 1.00 | 1.00 |

## 3.5

Recruitment estimates
Indices of 0-ringer abundance on the spring Spawning herring in Subdivisions 22-24 for 2003 were available from the larval surveys during the spawning season on the main spawning area (Table 3.3.5) and from the Acoustic survey (September/October). Log transformed indices were compared by year class in Figure 3.5.1. From 1990, the recruitment declined until 1992 when recruitment was the lowest observed in the time-series. From 1992, recruitment year classes, as estimated by the larval index, showed an increase with three large year classes in 1998, 1999 and 2002. Historical high recruitment of the 1998 and 1999 year classes were supported by 0 -ringer and 1 -ringer indices in the acoustic survey in Subdivisions 22-24 (Table 3.3.4). After 1998-1999, there was a significant drop in recruitment in 2000 while the 2002 and 2003 year classes have some of the largest values observed in the time-series. The larval index and the 0ringer from the acoustic survey showed very similar trends in the last 5 years.

### 3.6 Stock Assessment

### 3.6.1 Data Exploration and preliminary Modelling

### 3.6.1.1 Input data

Catch in numbers by age in Subdivision IVa (East), Division IIIa and Subdivisions 22-24 were available for 1991 to 2003 (Table 3.6.1) and as proportion at age (Figure 3.6.1). Catches were updated for 1995-2001 (see section 3.1.5). Years before 1991 have been excluded due to lack of reliable data for splitting spawning type and a large change in fishing pattern caused by changes to the German fishing fleets.Mean weights-at-age in the landings are found in Table 3.6.2 and in Figure 3.6.2. The proportions of F and M before spawning was assumed constant between years. F-prop was set to be 0.1 and M-prop 0.25 for all age groups. Natural mortality was assumed constant at 0.2 for all years and 2+ ringers. A predation mortality of 0.1 and 0.3 was added to the 0 and 1 ringers, which resulted in an increase in their natural mortality to 0.3 and 0.5 , respectively (Table 3.6.4). The estimates of predation mortality were derived as a mean for the years 1977-1995 from the Baltic MSVPA (ICES 1997/J:2).

Available survey indices were:
FLT1: Hydroacoustic survey in Division IIIa and Subdivision IVa East, July 1989-2003, 0-8+ ringers
FLT2: Hydroacoustic survey in Subdivisions 22, 23 and 24, Oct. 1989-2003, 0-8+ ringers
FLT3: IBTS in Division IIIa, Quarter 1, 1991-2004, 1-5 ringers
FLT4: IBTS in Division IIIa, Quarter 3, 1991-2003, 1-5 ringers
FLT5: Larvae survey in Subdivision 24 (Greifswalder Bodden), March-June 1977-2003
All are age-structured indices with Flt 5 used as an index of recruiting 0-ringers.

None of the indices covered the total spatial distribution of the WBSS stock and the indices covered the following quarters and areas:

| Survey area | Quarter 1 | Quarter 2 | Quarter 3 | Quarter 4 |
| :--- | :--- | :--- | :--- | :--- |
| Division IIIa | FLT3 |  | FLT1 and FLT4 |  |
| Subdivisions 22-24 | FLT5 | FLT5 |  | FLT2 |

Subsets of these data series representing selected age groups were constructed to give a better representation of the stock (see section 3.6.1.3).

### 3.6.1.2 ICA settings

A variety of ICA settings were explored in 2003, and the most indicative of these were again looked at in 2004. The following settings were used for the Final run in 2003 and used again in 2004:

- The period for the separable constraint: 5 years (1999-2003).
- The weighing factor to all indices (lambda $=1$ ).
- A linear catchability model for indices $1,2,3$, and 4 , and both linear and power model for index 5 .
- The reference $F$ set at age 4 and the selection $=1$ for the oldest age.
- The catch data were down-weighted to 0.1 for 0 -ringer herring.

### 3.6.1.3 Exploration by individual survey indices

For the assessment in 2004, the following individual survey time-series were used to tune catches in the different exploratory runs.

- FLT 1a: DK Hydroacoustic survey in Division IIIa + SD IVaE, July 1991-2003, excl. 1999, 0-8+ ringers
- FLT 1b: DK Hydroacoustic survey in Division IIIa+ SD IVaE, July 1991-2003, excl. 1999, 2-8+ ringers

FLT 1a, and 1b are different subsets of the hydroacoustic suvey in Division IIIa in July leaving out the 1999 cruise due to only partial coverage of the area, a different method (vs count) of stock identification, a different research vessel (the Norwegian R/V GO Sars), and a different acoustic set up. FLT 1a was the total 1991-2003 time-series with all age groups $0-8+$ ringers. In FLT 1 b the 0 and 1-ringers were excluded since only a small fraction of the WBSS have migrated to the Division IIIa at these ages.

- FLT 2a: GER Hydroacoustic survey in Subdivisions 22, 23 and 24, Oct. 1991-2003, 0-8+ ringers
- FLT 2b: GER Hydroacoustic survey in Subdivisions 22, 23 and 24, Oct. 1991-2003, 0-5 ringers

FLT2a contains all age-classes in the German hydroacoustic survey in the Western Baltic (Subdivisions 22-24) and is adjusted into FLT2b by excluding the oldest age classes.

- FLT 3: IBTS in Kattegat, Quarter 1, 1991-2004, 1-5 ringers

FLT3 is referring to the Swedish IBTS survey covering the Kattegat in quarter 1. No data are available for 2001 due to the lack of data for separation of stock components.

- FLT 4: IBTS in Kattegat, Quarter 3, 1991-2003, 1-5 ringers

FLT4 is referring to the Swedish IBTS survey covering the Kattegat in quarter 3. No survey was carried out in 2000. Old age-classes (6-8+ ringers) are very poorly represented in these IBTS surveys and therefore excluded from the selected indices.

- FLT 5a: Larval survey in Subdivision 24 (Greifswalder Bodden), March-June 1991-2003 excluding 1998, linear model
- FLT 5b: Larval survey in Subdivision 24 (Greifswalder Bodden), March-June 1991-2003, excluding 1998, power model

FLT5 is the German larval survey conducted in Subdivision 24 on estimating the abundance 30 mm larvae to give an estimate of the recruitment from the Rügen spawning grounds. FLT5a using linear catchability assumption and FLT5 b using a power model are subsets of FLT5 excluding 1998 due to hydrographical anomalies.

Exploratory runs of catch data with single indices were performed using the general ICA-setting mentioned earlier (Section 3.6.1.2). A summary of the results from these runs is presented in Figures 3.6.3 and 3.6.4.

The runs with the larval survey index only including all years and using a power model did not exhibit a realistic F value. The hydroacoustic survey indices in Division IIIa (FLT1a and FLT1b), the IBTS in Kattegat Q3 (FLT4) and the Acoustic survey in Subdivisions 22-24 (FLT2a and FLT2b) suggest intermediate F of between 0.4-0.5. On the other hand, the IBTS in Kattegat Q1 (FLT3) indicate a very high F of 0.8 while the larval survey in Subdivision 24 (FLT5a and FLT5b) give extreme opposite indications of fishing mortality depending on the chosen model the data; power( $\mathrm{F}<0.15$ ) and linear catchability ( $\mathrm{F}>3.7$ ).

The larvae survey FLT5 (N30) predicts strong and weak year classes very well but does not reflect the actual magnitude of year class strength. This results in a strong correlation, but large residuals when fitted in the ICA model to the catch data. A longer time-series may help resolve these issues, particularly if intermediate N30 values appear in the time-series. Although the larval survey does not add information to the current specification of the ICA model, it appears to function well as an indicator of recruitment. Trends in log transformed values of recruitment indices (larval index total time-series, 0 -ringer Acoustic in SD 22-24 and 1-ringer Acoustic in SD 22-24) show concordance in recent years (Figure 3.5.1). In the North Sea, the long MIK time-series (on post larvae) works well as an indicator of 0 ring year class strength in the ICA model. The larvae N30 is an abundance index of post-larvae in some ways similar to the MIK index, so potentially maybe of use in the future. The N30 index provides extremely valuable information on the general biology and year class development of the WBSS herring population.

## Conclusion

After exploring combinations of settings it was decided for the 2004 final run to choose:

- FLT1b (hydroacoustic survey in Division IIIa+ SD IVaE, 2-8+ ringers, excluding 1999),
- FLT2b (hydroacoustic survey in Subdivisions 22-24, 0-5 ringers) and
- FLT4 (IBTS $3^{\text {rd }}$ quarter survey in the Kattegat, 1-5 ringers).

The biological reasoning behind the choice of indices with restricted numbers of age classes is that there is only a partial migration of age $0-1$ ringers to the Division IIIa in the summer and that ages older than 5 -ringers are poor represented in the Subdivision 22-24 acoustic surveys and in the IBTS. The settings for the final ICA run for the 2004 assessment were the same as in the last year assessment.

This choice of final run is similar to the 2003 final run.

### 3.6.2 Final Assessment

This assessment conforms to an update assessment of WBSS herring, input data (years 1991-2003, Ages 0-8+ ringers) are given in the following tables:

- Catch in number (Table 3.6.1)
- Weight in catch (Table 3.6.2)
- Weight in stock (Table 3.6.3)
- Natural mortality (Table 3.6.4)
- Maturity (see text table in section 3.4)

The following surveys were included (Tables 3.6.5a-c):

- FLT 1b: DK Hydroacoustic survey in Division IIIa+ SD IVaE, July 1991-2003, excl. 1999, 2-8+ ringers
- FLT 2b: GER Hydroacoustic survey in Subdivisions 22, 23 and 24, Oct 1991-2003, 0-5 ringers
- FLT 4: IBTS in Kattegat, Quarter 3, 1991-2003, 1-5 ringers

The final model settings are shown in Table 3.6.6. The output data are given in Tables 3.6.7-3.6.16. The estimated SSB for 2003 is 158,000 tonnes with a mean fishing mortality (ages 3-6) of 0.38 (Table 3.6.9). The model diagnostics show a rather well defined minimum SSQ response-curve for all age-indices except age-index 1 (Acoustic Survey in Division IIIa+IvaE) that is somewhat flat (Figure 3.6.5). The minimum SSQ for the Acoustic Survey in SD 22-24 (ageindex 2) finds an intermediate compromise between the high F of age-index 1 (Acoustic Survey in Division IIIa+IvaE) and the low F of age-index 3 (IBTS Kattegat Q3). The stock summary is shown in Figure 3.6.6 and Table 3.6.9.

The marginal totals of residuals between the catch and the separable model are overall small, with almost no residuals for younger ages and a small increasing trend at older ages 4-7 as well as a reasonably trend-free separable period (1999-2003) but a somewhat large year effect in the final year (2003) (see Figure 3.6.7 but note that the apparent high 2001 year effect is caused by 0-ringers that are down-weighted in the analysis but still appears with full weight in the residual plots of the ICA diagnostics). For values see Table 3.6.12.

The Acoustic Survey in Division IIIa + IVaE and the Acoustic Survey in SD22-24, showed high negative residuals for 2003 (Figure 3.6.11). This pattern was similar for all ages in both surveys except for age 0 and 1 in the Acoustic Survey in SD22-24. This was contrasted by large positive residuals for all ages in the IBTS Kattegat Q3 survey.

The catch-at-age variance component is smaller than each the individual survey variance components and also smaller than the value in Table 3.6.16, unweighted statistics, where down-weighting of the 0 -ringers is not accounted for. Among the survey indices, the IBTS has the largest variance component with the two acoustic indices showing variances of about half to two thirds of the IBTS survey (Table 3.6.16).

After a decrease from a period of high fishing mortality in the mid 1990s, the $F$ values in the recent 5 years have been fluctuating between 0.38 and 0.45 . The SSB shows a slight increasing trend over the recent years after a marked decline in the mid 1990s.

The fit of the surveys to the population number by age class is similar between the Division IIIa acoustic survey (Figures 3.6.8a-g) and Subdivisions 22-24 acoustic survey (Figures 3.6.9a-g) (FLT1b and FLT2b respectively). both surveys exhibit the best fit for intermediate ages 3-5 ringers, and neither survey has an annual trend in residuals although Subdivisions 22-24 acoustic survey has lower catchability values than the Division IIIa survey (Table 3.6.11). On the other hand, the Kattegat Q3 IBTS-index (FLT4) shows quite poor fit of catchabilities for the age classes 1-3
ringers but improving for the two oldest ages 4 and 5 ringers in the index (Figures 3.6.10a-e). The reason for the poorer performance of the Kattegat Q3 IBTS survey may be an increased redistribution of immature age-classes into the Kattegat area in the recent one or two years.

## Overall trends in the age structured data for the ICA model

Exploring the cohort dynamics by log catch and log survey indices gives an indication of overall mortality and catchability in successive cohorts from year classes 1991-2000 (Figures 3.6.8a-d). Slopes of log catches do not indicate any increasing trend in mortality (Figure 3.6.12a). Slopes from the Subdivision 22-24 acoustic survey are relatively stable (Figure 3.6.12c) whereas for IBTS in Kattegat it shows fluctuation with initially increasing negative values followed by decreasing negative slopes from the 1994 cohort (Figure 3.6.12d). An opposite increasingly negative trend in slopes is found in the log Division IIIa acoustic survey (Figure 3.6.12b). Generally, the trends may be interpreted as an overall stable to decreasing fishing mortality from 1994.

The signal from the catches is relatively stable whereas the survey indices are more scattered and somewhat conflicting, but together provide a compromise in line with the catch information.

### 3.7 Short-term Projection

The assessment was used to provide a yield-per-recruit plot for herring in Division IIIa and Subdivisions 22-24 (Figure 3.7.1). The values for $\mathbf{F}_{0.1}$ and $\mathbf{F}_{\max }$ are 0.20 and 0.40 , respectively.

Short-term predictions were carried out using MFDP v.1a software. ICA estimates of population numbers and fishing mortalities were used except for the numbers of 0-ringers in 2003-2006, where the geometric mean of the recruitment over the period 1992-2001 was taken, and for the numbers of 1-ringers in 2003, where the geometric mean over the period 1993-2002 was used. Mean weights-at-age in the catch and in the stock were taken as a mean for the years 2001-2003. A status quo exploitation pattern for 2004 was assumed, with values rescaled to the last year estimate. Input data for catch predictions are presented in Table 3.7.1.

Short-term predictions were carried out assuming a status quo fishing mortality for 2003. For 2004 onwards either status quo F or $\mathbf{F}_{\text {max }}$ were used for the predictions. Single options tables are available for 2004 and 2005 (Tables 3.7.2 and 3.7.4).

| Scenario | 2004 | 2005 | 2006 |
| :--- | :--- | :--- | :--- |
| 1) status quo F | $\mathrm{F}_{2004}=\mathrm{F}_{2003}=0.385$ <br> Status quo F <br> Catch $=86,700 \mathrm{t}$ | $\mathrm{F}_{2004}=\mathrm{F}_{2003}=0.385$ <br> Status quo F <br> Catch $=91,500 \mathrm{t}$ | $\mathrm{F}_{2004}=\mathrm{F}_{2003}=0.385$ <br> Status quo F <br> Catch $=95,000 \mathrm{t}$ |
| 2) status quo F <br> followed by $\mathrm{F}_{\max }$ | $\mathrm{F}_{2004}=\mathrm{F}_{2003}=0.385$ <br> Status quo F <br> Catch $=86,700 \mathrm{t}$ | $\mathrm{F}=0.74 * \mathrm{~F}_{2003}=0.40$ <br> $\mathrm{~F}_{\max }=0.40$ <br> Catch $=95,800 \mathrm{t}$ | $\mathrm{F}=0.74 * \mathrm{~F}_{2003}=0.40$ |
| $\mathrm{~F}_{\max }=0.40$ |  |  |  |
| Catch $=98,000 \mathrm{t}$ |  |  |  |

The results of the short-term predictions are given in Tables 3.7.2 - 3.7.4. Table 3.7.2 shows single option predictions for 2004-2006 and Table 3.7.3 multiple options for 2005 at status quo fishing mortality. The catches for 2005 and 2006 at status quo fishing mortality were predicted to be $91,000 \mathrm{t}$ and $95,000 \mathrm{t}$, respectively, which is an overall increase in relation to the current catch level of $78,000 \mathrm{t}$. The SSB is predicted to increase to $185,000 \mathrm{t}$ in 2005 and to $194,000 \mathrm{t}$ in 2006.

Table 3.7.4 shows single option predictions for 2005 and 2006 at status quo fishing mortality for 2004 and $\mathbf{F}_{\text {max }}$ in 2005 and 2006, respectively. The catches for 2005 and 2006 at $\mathbf{F}_{\max }$ were predicted to be $96,000 \mathrm{t}$ and $98,000 \mathrm{t}$, respectively, which is an overall increase in relation to the current catch level. The SSB in 2005 and 2006 is predicted to increase to $184,000 \mathrm{t}$ and $190,000 \mathrm{t}$, respectively.

### 3.8 Reference Points

Reference points have neither been defined nor proposed for this stock (see Section 1.7). The time-series is short with revised catch data and reliable splitting factors for only 13 years, the estimated SSB has not been below $116,000 \mathrm{t}$ since 1991 and there is no obvious stock-recruitment relationship.

### 3.9 Quality of the Assessment

### 3.9.1 Sensitivity of the assessment to variability in the input data

Prior to this year's assessment a revision of the catch-at-age data was performed, however, the changes do not seem to influence the results and the ICA assessment model appears to perform generally well under a five-years-
separable assumption. Western Baltic spring spawners dominate 2003 catches of 0-group herring taken in Division IIIa. However, since representation of WBSS 0-ringers is varying and this component is generally not well represented in the catch, the numbers are highly influenced by split-data for separation of the two stocks and 0 -group herring in catches are subsequently down-weighted.

The influence of different surveys was investigated by repeating key exploratory runs from last year's assessment. Generally surveys behaved quite similarly this year compared to last year. The larval survey was found to be heavily influenced by noisy years and no solution was found when 1998 was included. Opposite and extreme results from the larval survey depending on a linear or a power catchability model indicate this to be unreliable at present. The $1^{\text {st }}$ quarter IBTS estimates a quite low SSB and a high F with high residual values. These results were quite in line with the 2003 year's assessment, and lead to the subsequent exclusion of these indices from the final model run.

A comparison of the estimates of SSB based on the information from the individual surveys and the combination of all three is illustrated in Figure 3.9.1.1. A similar signal in relation to SSB is picked up from all indices. Estimates of annual F for the separable period appear to be quite precise (CVs in the order of 12-15\%), and reinforce the perception of high fishing pressure on this stock, which was suggested by previous year's analyses.

Bootstrap analyses were performed using the variance-covariance matrix output from the ICA under the assumption of multinomial distributed errors. These estimates give an indication of the minimum uncertainty in the trends of the stock dynamics with the assumed error distribution (Figure 3.9.1.2). The results indicate that fishing mortalities probably have declined from historic high values in the mid 1990s whereas it is difficult to ascertain if SSB has increased since the lowest value in 1998. Recruitment pattern indicate a high year class in 1999 and a distinctively low one in 2002.

### 3.9.2 Comparison of ICA with XSA

For comparison an XSA run was investigated the settings with a shrinkage of 0.5 are presented in Table 3.9.2.1 and the stock summary in Table 3.9.2.2. The results of the two assessment methods show the same trends in SSB and are differing with no more than $25 \%$ in the final year (Figure 3.9.2.1). When the XSA assumptions are similar to those used in ICA (XSA with no shrinkage, the full data set for all the survey used to obtain the survey catchability (Q)), differences are larger than when shrinkage is included. However, the perception of a stock with a slightly increasing SSB to around 150 thousand tonnes in recent years and a slight drop in the final year of 2003 is apparent in all cases.

### 3.9.3 Comparison with earlier assessments

For the ICA model five years of retrospective patterns were investigated in accordance with a fixed separable period five years. No evident pattern in SSB is apparent whereas there is some bias in the retrospective F-pattern evident as a repeated underestimation of fishing mortality in the final year (Figure 3.9.3.1). As for last year's assessment, the recruitment estimates are noisy for the most recent years (Figure 3.9.3.1). The selection pattern over ages exhibited a reasonable smooth increasing pattern for all retrospective runs, however a similar bias, as found for the F-pattern, appears as a decreasing selection over the 5 year period for all non reference ages (Figure 3.9.3.2).

A retrospective analysis was also performed using the XSA (with shrinkage 0.5). Compared to the ICA patterns the XSA retrospective SSB, fishing mortality and recruitment was less noisy (Figure 3.9.3.3).

The comparison between the results of the HAWG-2003 and HAWG-2004 assessments shows a high similarity with 2-5 percent difference in the SSB and fishing mortality for 2002 (see the following text table).

| Category | Parameter | Assessment 2003 | Assessment 2004 | $\begin{gathered} \text { Diff. } \\ (+/-) \% \end{gathered}$ |
| :---: | :---: | :---: | :---: | :---: |
| ICA input | No. of years for separable constraints <br> Reference age for separable constraint <br> Selection to be fixed on last age <br> Weighting factor to all indices <br> Catch down-weighted to 0.1 for 0 -ringer Tuning data | 5 | 5 | No |
|  |  | 4 | 4 | No |
|  |  | 1 | 1 | No |

|  |  | IBTS Surv. Quarter 3 | IBTS Surv. Quarter 3 | No |
| ICA results | SSB 2002 | 177,000 t | 185,970 t | +5\% |
|  | F(3-6) 2002 | 0.47 | 0.48 | +2\% |

### 3.10

Management Considerations
The stock in Division IIIa is at present managed in accordance with the North Sea herring stock because a considerable proportion of the juveniles of that stock are present in Division IIIa. The herring fishery in Subdivisions 22-24 is managed in accordance with the whole Baltic area as only one TAC is set for that area.

This year's assessment corroborates the perception that the Western Baltic Spring-spawning herring stock is slowly increasing from the low SSB level in 1998. However, $\mathrm{F}_{3-6}$ still appears to be high compared to other herring stocks in European waters, but still below $\mathbf{F}_{\text {max }}$.

Increasing German landings from Subdivisions 22 and 24 have counterbalanced decreasing Danish landings in 2002 and 2003. An increasing fishing pressure in the coming years may be expected due to the opening of a new herring processing plant at Rügen.

Short-term predictions demonstrate that a status quo fishing mortality and geometric mean recruitment would lead to an increase of both yield and SSB in 2004. Different scenarios for 2005 and 2006 show an increase of yield and SSB for the two years for both $\mathbf{F}_{\mathrm{sq}}$ and $\mathbf{F}_{\max }$. Considering that SSB in recent years (1998) has been historically low and that fishing mortality is still relatively high, the WG recommends to limit the fishing mortality effectively to no more than $\mathbf{F}_{\text {max }}$ for 2005. This would equal a yield of about $96,000 \mathrm{t}$.

Following the rebuilding of the North Sea stock to levels around 2 million $t$, the TACs for NSAS herring have increased. The two stocks are exploited simultaneously in Division IIIa. However, due to asynchronous population dynamics of herring in the North Sea, the Central Baltic and the Western Baltic/Division IIIa, the WG repeats that a proper management of the Western Baltic Spring-spawning herring stock requires a management regime that is separated both from herring in the Central Baltic and in the North Sea. The need for a separate TAC set for the area where WBSS herring is distributed, i.e. Division IIIa and Subdivisions 22-24 should be considered with urgency.

|  | 7 | 77.8\% | 22.2\% |  |  | 10.7\% | 89.3\% |  |  |
|  | 8+ | 77.8\% | 22.2\% |  |  | 10.7\% | 89.3\% |  |  |

Proportions as \% are calculated using combined otolith microstructure data from Danish and Swedish catches in 2003

Age-classes with few analyses were joined into plus-groups with more than 11 individuals and indicated by numbers in italics. In the source column the constructed plus groups are indicated. For 0-ringers in Q3 the proportion from the Acoustic survey in Skagerrak was used.

Type * to change language
Enter the name of the index file -->index.dat
canum.low
weca.low
Stock weights in 2004 used for the year 2003
west.low
Natural mortality in 2004 used for the year 2003
natmor.low
Maturity ogive in 2004 used for the year 2003
matprop.low
Name of age-structured index file (Enter if none) : -->DAGAIYFD.dat
Name of the SSB index file (Enter if none) -->
No indices of spawning biomass to be used.
No of years for separable constraint ?--> 5
Reference age for separable constraint ?--> 4
Constant selection pattern model (Y/N) ?-->y
$S$ to be fixed on last age ?--> 1.000000000000000
First age for calculation of reference $F$ ?--> 3
Last age for calculation of reference $F$ ?--> 6
Use default weighting (Y/N) ?-->n
Enter relative weights at age
Weight for age 0--> 0.100000000000000
Weight for age 1--> 1.000000000000000
Weight for age 2--> 1.000000000000000
Weight for age 3--> 1.000000000000000
Weight for age 4--> 1.000000000000000
Weight for age 5--> 1.000000000000000
Weight for age 6--> 1.000000000000000
Weight for age 7--> 1.000000000000000
Weight for age 8--> 1.000000000000000
Enter relative weights by year
Weight for year 1999--> $\quad 1.000000000000000$
Weight for year 2000--> 1.000000000000000
Weight for year 2001--> 1.000000000000000
Weight for year 2002--> 1.000000000000000
Weight for year 2003--> 1.000000000000000
Enter new weights for specified years and ages if needed
Enter year, age, new weight or $-1,-1,-1$ to end. -1 -1 -1.000000000000000
Is the last age of Acoustic Survey in Div IIIa+IVaE Ages a plus-group (Y/-->y
Is the last age of Acoustic Survey in Sub div 22-24 Ages 0- a plus-group (Y-->n
Is the last age of IYFS Katt Quart3 Age groups 1-5 (Mean Ca a plus-group (Y-->n You must choose a catchability model for each index.

Models: A Absolute: Index = Abundance . e
$L$ Linear: Index $=$ Q. Abundance . e
$P$ Power: Index $=$ Q. Abundance^ $K$.e
where $Q$ and $K$ are parameters to be estimated, and e is a lognormally-distributed error.

Model for Acoustic Survey in Div IIIa+IVaE Ages is to be A/L/P ?-->L Model for Acoustic Survey in Sub div 22-24 Ages 0- is to be A/L/P ?-->L Model for IYFS Katt Quart3 Age groups $1-5$ (Mean Ca is to be A/L/P ?-->L Fit a stock-recruit relationship (Y/N) ?-->n
Enter lowest feasible $F-->5.0000000000000003 \mathrm{E}-02$
Enter highest feasible F--> 1.000000000000000

Table 3.9.2.1 WESTERN BALTIC HERRING. Model settings for XSA with shrinkage $=0.5($ age $=$ ringer $)$
CPUE data from file dagaiYFd.dat
Catch data for 13 years. 1991 to 2003. Ages 0 to 8 .
Fleet,
First, Last, First, Last, Alpha, Beta
year, year, age, age
FLT 1b: Acoustic Survey in Div. IIIa+IVaE, 1991, 2003, 2, 7, .580, . 670
FLT 2b: Acoustic Survey in SD 22-24, 1991, 2003, 0, 5, .770, . 830
FLT 4: IBFS Katt Quart3, 1991, 2003, 1, 5, .500, . 750
Time series weights :
Tapered time weighting applied
Power $=3$ over 20 years
Catchability analysis :
Catchability dependent on stock size for ages $<2$
Regression type $=\mathrm{C}$
Minimum of 5 points used for regression
Survivor estimates shrunk to the population mean for ages $<2$
Catchability independent of age for ages $>=5$
Terminal population estimation :
Survivor estimates shrunk towards the mean F
of the final 5 years or the 5 oldest ages.
S.E. of the mean to which the estimates are shrunk $=\mathbf{. 5 0 0}$

Minimum standard error for population
estimates derived from each fleet $=.300$
Prior weighting not applied
Tuning converged after 23 iterations

Table 3.9.2.2

## 4 Celtic Sea and Division VIIj Herring

## Introduction

The herring fisheries to the south of Ireland in the Celtic Sea and in Division VIIj exploit autumn and winter spawning components. For the purpose of stock assessment and management, these areas have been combined since 1982. The areas for which the assessments are made, together with the area for which the TAC is set by the EU are shown in Figure 1.5.1. The management unit covers all of Divisions VIIg,h,j and k and the southern part of Division VIIa. In the past season, Ireland was the sole participant in the fishery which takes place in VIIg, VIIj and VIIa(S). This has been the case for several recent years.

### 4.1 The Fishery in 2003-2004

### 4.1.1 Advice and management applicable to 2003-2004

The TAC in 2003, was $13,000 \mathrm{t}$. In 2003 ICES considered the status of this stock to be unknown. ACFM advised that catches in 2004 should not exceed $40 \%$ of the average catches in 1997-2000 corresponding to catches of less than $11,000 \mathrm{t}$. This was expected to allow SSB to increase. $\mathbf{B}_{\mathrm{pa}}$ is set at $44,000 \mathrm{t}$ and $\mathbf{B}_{\mathrm{lim}}$ at $26,000 \mathrm{t}$. F reference points are not defined for this stock. The TAC is set on a calendar year basis.

The fishing season runs from the $1^{\text {st }}$ April 2003 to the $31^{\text {st }}$ March 2004, though the fishery was traditionally only opened on the $1^{\text {st }}$ October. In the current season, the fishery was allowed to remain open throughout. This was to allow vessels to target fish outside the spawning seasons when the fish are of better quality and marketability. The spawning box closures implemented under EU legislation continued. Box A was closed in the 2003-2004 season and Box B will be closed in November 2004 (Fig 4.1.1.1). In addition to these, Box A was voluntarily closed in the recent seasons. This initiative was initiated by the Irish Southwest Pelagic Management Committee to afford extra protection to first time spawners. This box was re-opened from December 2003, for the remainder of the season. Areas mentioned in the text are shown in Figure 4.1.1.2.

The Irish Southwest Pelagic Management Committee was established to manage the Irish fishery for this herring stock. This committee, therefore, has responsibility for management of the entire fishery for this stock at present. The committee has the following objectives:

- To build the stock to a level whereby it can sustain annual catches of around $20,000 \mathrm{t}$.
- In the event of the stock falling below the level at which these catches can be sustained the Committee will take appropriate rebuilding measures.
- To introduce measures to prevent landings of small and juvenile herring including closed areas, and or appropriate time closures.
- To ensure that all landings of herring should contain at least $50 \%$ of individual fish above 23 cm .
- To maintain and if necessary expand, the spawning box closures in time and area.
- To ensure that adequate scientific resources are available to assess the state of the stock.
- To participate in the collection of data and to play an active part in the stock assessment procedure.

The TAC is set by calendar year, whilst the assessment of this stock is conducted on a seasonal basis ( $1^{\text {st }}$ April to $31^{\text {st }}$ March). The TAC in 2003 was $13,000 \mathrm{t}$. Ireland has $86.4 \%$ of the quota with, France and the Netherlands having most of the remainder. The Irish quota in 2003 was $11,235 \mathrm{t}$. This is managed by allocating individual quotas to vessels. Participation in the fishery is restricted to licensed vessels. The licensing requirements have been changed. Previously, vessels had to participate in the fishery each year to maintain their licence. Now this requirement has been lifted. This has been one of the contributory factors in the considerable reduction in number of vessels participating in the fishery in recent seasons.

Fishing is restricted to the period Monday to Friday each week, and vessels must apply a week in advance before they are allowed to fish in the following week.

### 4.1.2 The fishery in 2003/2004

In recent years, this fishery has been prosecuted entirely by Ireland. The landings in this fishery since 1958 are shown in Figure 4.1.2.1. The fishing season is the same as the assessment period, $1^{\text {st }}$ April to the $31^{\text {st }}$ March the following year. Traditionally, the fishery was closed in February each year. In the current season, however, the fishery remains open at present.

The main fishery was during the late summer and early autumn at the Kinsale Head Gas Field and the Labadie Bank. The fish at this time were much bigger and of better marketability than the inshore catches. The area off Dunmore East, which had been voluntarily closed for at least two years, was reopened in December 2003. Between July and the start of the traditional spawning season fishery in October, approximately $4,500 \mathrm{t}$ were landed.

Landings were $10,875 \mathrm{t}$. The total Irish quota was subdivided into boat quotas on a week-by-week basis. In addition to the spawning aggregations fished along the south coast between Waterford and Cork, the off-shore feeding aggregations on the Labadie bank and the Kinsale gas platforms, intermittent landings were also made from the coastal waters of ICES division VIIj. A map of the locations mentioned in the text is given in Figure 4.1.1.2. In this season a total of 10 vessels participated, though only 6 were involved on a regular basis. In 2002-2003, 8 vessels were involved as compared with 33 vessels for 2001/2002 season and 30 for the 2000/2001 season (Figure 4.1.2.2). The markets throughout the season were very poor because of the large catches of herring from the North Sea fishery. The profitability of this Irish fishery was considerably hampered, and led to reduced effort.

The fishery in the third quarter caught larger fish than those caught in the winter fishery (Table 4.2.3.2). See also Figure 4.3.1.2 for comparisons of length distributions.

### 4.1.3 The catches in 2003/2004

The estimated national catches from 1988-2003 for the combined areas by year and by season (1 April-31 March) are given in Table 4.1.3.1 and Table 4.1.3.2 respectively. The total catches for the fishery over the longer period from 1958 to 2002 are shown in Figure 4.1.2.1 The catch, taken during the 2003/2004 season was about $11,000 \mathrm{t}$ having increased from around $7,500 \mathrm{t}$ during the previous season.

## Discards

The level of discards in this fishery is believed to have decreased considerably in recent years with the decline in the demand for "roe" fish for the Japanese market. However there are no estimates of discarding in this fishery.

### 4.2 Biological Composition of the Catch

### 4.2.1 Catches in numbers-at-age

Catch numbers-at-age are available for the period 1958-2003. These data include discards, when estimates are available. In 2003/2004, $41 \%$ of the catch was composed of 2 -ringers ( $2001 / 2002$ year class) and $27 \%$ of the catch was composed of 3-ringers (2000-2001). The percentage of older fish in the current season (30\%) was higher than in 2002/2003, having been just $15 \%$ (Table 4.2.2.1). The greater proportion of older fish may be explained by the summer fishery, that took these large fish in VIIg and VIIj. The percentage of 1-ringers was $3 \%$ in 2003/2004, having been $6 \%$ in 2002/2003 (Table 4.2.2.1).

VIIaS was voluntarily closed in 2001 and reopened in early December 2003. Since reopening, catches from this area were dominated by 2 -ringers (2001/2002 year class), accounting for $62 \%$.

The Irish authorities, in conjunction with the Irish Southwest Pelagic Management Committee, kept the fishery open all throughout the season in 2003/2004. This initiative was based on the aim to catch the quota when the fish had a better condition factor and consequently less fish would be caught per tonne of quota than in winter time. The summer fishery accounted for most of the catches in this area, and the fish achieved a better price, in difficult marketing conditions for Irish herring. These fish were larger than the winter-caught herring (Table 4.2.2.2). In addition the proportions of 4 - to 8 -ringer fish was considerably higher than for the entire catches in the 2003/2004 season (Figure 4.3.1.2).

The numbers of herring per tonne (as live fish equivalents) was estimated as 6,554 in the third quarter in VIIg in contrast to 9,405 per tonne in the first quarter of 2004. These data were calculated from mean weights-at-age.

In 2001, the Irish Southwest Pelagic Management Committee, initiated a voluntary closure of spawning box C. This was in addition to the rotating closure of the other boxes in the region (Figure 4.1.1.1). This box was finally reopened in early December 2003. This opening was accompanied by sampling of the catches. The catches since then, were dominated by 2 -ringers ( $62 \%$ ) and 3 -ringers ( $24 \%$ ). This age distribution agrees well with the composition of the large aggregations identified in this area during the acoustic survey (Figure 4.3.1.2).

### 4.2.2 Movements of Juvenile fish

A recent study on herring otolith microstructure has elucidated several points with respect to the natal origin of juvenile herring in the Irish and Celtic Seas (Brophy and Danilowicz, 2002). The results show that fish spawned in the eastern Celtic Sea are present as larvae in the Irish Sea, where fish of local origin are also found. The fish of Celtic Sea origin then return to that area as 1 - and 2-ringers. These results show that juvenile distribution affects length-at-age for 0 ring fish and subsequently influences age at recruitment.

### 4.2.3 Quality of catch and biological data

Since 1997 there has been a major increase in the monitoring of landings from this fishery and the management measures were again tightly enforced throughout the season. As a result the accuracy of the landing figures is considerably better for this period.

Biological sampling of the catches throughout the area increased, relative to last season. This was achieved by cooperation between members of the Irish Southwest Pelagic Management Committee, including fisheries officers, fishermen, skippers and processors. Length distributions of the catches taken by the Irish fleet per quarter are shown in Table 4.2.3.2. Details of the sampling data per quarter are shown in Table 4.2.3.3. A particular difficulty was the paucity of samples from VIIj. However, steps have been taken to rectify this problem.

### 4.3 Fishery Independent Information

### 4.3.1 Acoustic Surveys

A series of acoustic surveys have been carried out on this stock from 1990-1996. The series was interrupted in 1997 due to the lack of the survey vessel, it was resumed in 1998. For the 2002/2003 season one acoustic survey was carried out to determine stock abundance. It was decided that a single survey carried out on fish approaching the grounds would be sufficient to contain the stock. A review of this survey series is in preparation (Table 4.3.1.1). The references cited are dealt with by O'Donnell et al. (in prep.).

In 2003, one acoustic survey was carried out in October and November (O'Donnell WD, 2004). This single survey was aimed at pre-spawners as they move inshore to spawn. The survey track was begun at the northern boundary of VIIj, and moved south and then eastwards, ending in VIIaS (Figure 4.3.1.1a). The largest concentrations of herring were located at the eastern part of the area, in the Waterford Harbour and immediately east of Dunmore East. This area had been voluntarily closed since 2001. NASC values, assigned to herring, from this area contribute to over $75 \%$ of the total values obtained (Figure 4.3.1.1b).

Concentrations of small isolated herring traces were observed in the northern part of VIIj. Offshore occurrence of NASC values attributed to herring was extremely low in comparison to previous surveys in the Celtic Sea. The geographical positioning of the NASC values obtained along the southwest and south coasts closely mirror that of the pattern of fleet activity.

The composition of the aggregations in the Waterford Harbour/Dunmore East (VIIaS) was dominated by 2ringers, but this age distribution was not observed elsewhere in the survey area. Fish of three winter rings predominated in VIIj. In the south western part of VIIg, 0 - and 1-ring fish predominated. Because the aggregations in VIIaS accounted for around $75 \%$ of the biomass and numbers, the age structure of the overall biomass estimate is dominated by 2-ringers. Figure 4.3.1.2 compares the age distribution of commercial catches with the acoustic abundance estimate. The 2-ringers are dominant in both, but the percentage of 3-ringers is proportionately greater in the survey. These fish were located in VIIj, though they accounted for only $19 \%$ of the overall acoustic estimate.

The majority of the fish were mature, accounting for $87 \%$ of the biomass estimate and $85 \%$ of the total numbers, indicating that the survey timing was good and major spawning had not taken place. A small proportion of spent fish were also present indicating that some of the stock had just spawned. The majority of the traces were recorded close inshore, and this would suggest that the stock had migrated towards the spawning grounds. Fishing success was reasonably good. Around $50 \%$ of the biomass was generated by the VIIaS aggregations, that were positively identified as herring, based on fishing. Elsewhere the estimate is less certain, as the majority of the traces were not identified with confidence.

The age structured index of biomass and numbers from acoustic surveys in this area, is shown in Table 4.3.1.2. The overall biomass estimate $(89,000 \mathrm{t})$ is considerably higher than in the previous season $(49,000 \mathrm{t})$. However, most of the biomass in the present survey was recorded from aggregation, described above, in VIIaS. The strong 3-ringer group in the 2003 survey was not well represented as 2 -ring fish in 2002 survey. In addition, 3 -ringers were less strongly represented in the commercial fishery. In VIIj in the fourth quarter of 2003, 3-ringers accounted for their greatest proportion of the catch ( $39 \%$ ), and this agrees well with the strength in that Division estimated by the acoustic survey. The relatively weak appearance of this year class in the previous year's survey may be explained by the poor coverage, particularly of VIIj, due to adverse weather conditions in autumn 2002.

### 4.3.2 Other surveys

In 2000 some information from a UK bottom trawl survey in the first quarter was made available to the HAWG. This information was useful in examining for major changes in Z in the previous year as indicated by the 1999/2000 acoustic survey index. While there was no updated information from this survey series available to the WG in 2004, the Irish Marine Institute will initiate a study of the western IBTS survey as a recruitment index for the 2005 WG.

In 2004, an initiative by the Irish Southwest Pelagic Management Committee led to an acoustic survey being conducted on a commercial vessel whilst actively fishing herring in VIIg. A pair team of vessels were actively targeting fish and had located several large aggregations. An ad hoc survey track was developed and echo integration was carried out using the EK60, by Seabed Surveys International Ltd. The estimate was based on tightly spaced tracks in an area where herring were aggregating at the time Biological data were collected for the catches associated with this work, by
the Irish Marine Institue. The preliminary results were available to HAWG. Though not age stratified, as yet, the overall biomass of the herring in this area was $42,800 \mathrm{t}$. This estimate is smaller than that obtained by the acoustic survey, but the area of coverage was much smaller.

### 4.4 Mean weights and maturity-at-age

The mean weights in the catch for this stock over time are presented in Figure 4.4.1. There has been an overall downward trend in mean weights-at-age since the mid-1980's, with current values among the lowest in the series.

In the past season, and for the first time in many years, a substantial catch was taken, outside the spawning season. The spawning season is considered to begin on the $1^{\text {st }}$ October and progresses through to mid February, in a generally west to east direction. Therefore the mean weights in the stock were calculated from samples taken in VIIg, VIIj and VIIaS from October 2003to February 2004. Summer samples were not used in these calculations. The mean weights were lower than previous years for all ages. This may reflect higher abundances of these year classes in the population.

The maturity-at-age for this stock has been assumed to be constant throughout the whole time period ( $50 \%$ of 1 ring fish are assumed to be mature at age 1 and $100 \%$ mature at 2 ring).

### 4.5 Recruitment

At present there are no recruitment estimates for this stock that can be used for predictive purposes. The modelled catch numbers-at-age from ICA, suggest that the recruitment of 1-ringers in 1999 and 2001 was above average, but that it was weaker in 1998, 2002 and 2003.

In this stock a proportion of juvenile fish are present in the Irish Sea and do not recruit to the Celtic Sea and Division VIIj until they are mature. Therefore neither the numbers of 1-ringers in the stock as estimated from the acoustic surveys nor the numbers in the catches give a reliable indication of year class strength. The relationship between the numbers of 1-ringers taken per hour in the Northern Irish ground fish surveys in the Irish Sea and the numbers of 1ringers estimated by ICA for the Celtic Sea and Division VIIj was examined in a working document presented to the 1999 WG (Armstrong et al., 1999) and the results suggest that these surveys may become a useful indicator of recruitment to the Celtic Sea and Division VIIj when a longer time-series is established. Recent information on mean length of 0 group herring (measured in October) in the eastern and western Irish Sea suggests that the proportion of juvenile herring from the Celtic Sea and Division VIIj stock in the Irish Sea may be relatively low in recent years.

### 4.6 Stock Assessment

### 4.6.1 Preliminary data exploration

Recent WG's have used the results of the acoustic surveys in the ICA programme but stated that the results should be taken as minimum estimates. In 1998 the WG decided to use the age-disaggregated data but only over the 2 to 5 -ringers as a relative index in the ICA programme, and this has been continued. The main difference between this year's assessment and that of 2003 was the change in the proportion of $F$ before spawning ( $=0.551$ in 2004) and the different procedure for estimating stock weights (see 4.4.4). In 2004, an examination of the $\log$ ratio of abundances in the survey index was carried out. This showed that there was both high frequency and low frequency noise in the acoustic survey abundances by age. The high frequency noise was associated with 0 - and 1 -ringers and fish older than 5 -ringer. This finding confirms the decision to restrict the acoustic index to 2 - to 5 - ringers. In addition, this analysis confirms the strong year effects in the survey too (Figure 4.6.1.1).

Exploratory runs were made by including the acoustic index as an SSB index also. This was achieved by using a power model in ICA. The results of this exploratory run, produced much higher estimates of recruitment than those where this series was not used. This is because the total SSB index includes all age groups, including 1-ringers. The model attempts to match the SSB proportion contributed by recruits, by inflating the modelled catch numbers-at-age. ICA could not adequately model the inconsistency between the catch-at-age and the non-age stratified SSB index. However it is clear from the acoustic survey that there is a predominance of young fish, particularly in VIIaS, and this signal may indicate increased numbers of younger fish in the population. The working group decided not to include the SSB as a separate index, due to this inconsistency.

In 2004, the working group considered a range of selections at oldest age. This was because there was concern that the pattern of exploitation has changed in recent years. There is a marked trend in log catch ratios (Figure 4.6.1.2). Since 1998/1999 the values have displayed an increasing trend. This may reflect increased F, though this seems unlikely given the decrease in landings in that time. It may also indicate a change in fishing pattern.

The mean of log transformed abundances of 2-5 ringers in the acoustic survey index is relatively stable over the time-series (Figure 4.6.1.3). However, the slopes of the survey curves are much higher than the signal that is received from the catch numbers-at-age data in the commercial fishery (Figure 4.6.1.4). This may be explained by different catchabilities of the older ages in the fishery, over the time period. It most likely also reflects the discarding of fish in the past. There is less information in the most recent years in these figures.

The update assessment run was taken as for last year with the new survey and catch-at-age data. In order to investigate the effects of changing fishing pattern and the sensitivity of the ICA model to different input values of selection on the oldest age. ICA was run for a range of terminal S values from 0.7 to 1.5 . The outputs from this analysis showed
that SSB and recruitment were not sensitive to differing proportions of terminal selection to the reference age. However higher terminal S inputs (0.7-1.5) produced higher F's ( $0.48-0.67$ ). Then, the effect of changing the extent of the separable period was examined by using 8 and 4 year periods. These changes did not effect the model outputs to any large extent.

The changes noted above, in separable period and terminal S did not improve the model fit. The update run was chosen as the final run. However, the inability of the assessment model to track changes in the exploitation pattern and the inconsistencies between the survey and the fishery should be noted. A table is given below showing the options used in the assessment since 1998.

Working Group

Age structured acoustic Index (ages 2-5 rings) 1990-1996 1990-1996, 1998

| No | $1997-2003$ |

### 4.6.2 Results of the assessment

The run log of this years assessment is shown in Table 4.6.2.1. The results of the assessment and the diagnostics are shown in Table 4.6.2.2 and Figures 4.6.2.1-4.6.2.8. The model suggests a downward trend in SSB throughout the 1990's, with a slight increase in 2002 and then a decline again. This downward trend accompanies a decline in the mean weights in the catch (Figure 4.4.1). However the estimate of SSB in the final year should be treated with caution because of the inherent uncertainty in the assessment and the higher estimate obtained from the acoustic survey, which there is reasonable confidence attached to. The increase in F in the final year can be explained by a higher catch in the current season. F declined since the early 1980's but showed a marked rise again in the late 1990's, before declining again. The long-term average $F$ for this stock has been about 0.54 , and current $F$ is close to this value. However recent landings have been well below the historical average.

The value of F in 2002 from the current assessment is 0.275 , lower than that estimated in the 2003 assessment (0.304). The estimate of SSB for 2002 from the current assessment is very similar to that estimated for that year in the previous assessment. Recruitment in 2002 estimated from the current assessment is higher than that estimated from the previous assessment. Overall the estimates F and SSB in the final year in the 2003 assessment and in the current assessment are in the same range. However the value of recruitment last year now appears to have been an underestimate (Figure 4.6.2.1).

Historical uncertainty was evaluated in the current assessment. The results of this analysis, based on 100 bootstrapped samples of residuals, are presented in Figure 4.6.2.9. There is a large uncertainty in the estimate of SSB and recruitment between 1993 and 2000. The uncertainty around the recruitment in 2003 increased markedly again, and this was found to a lesser extent for SSB too. The uncertainty around estimates of mean F also increased in this time period, though the 2002 estimate was low. This may be explained by the low landings in that year. The reasons for these uncertainties are difficult to elucidate. However it is clear that the uncertainty has reduced somewhat in recent years, and this may reflect the improved reporting of catches that has taken place in this period.

### 4.6.3 Comments on the assessment

The working group has now tracked the historical uncertainty in this assessment for two years in a row. There clearly has been some changes in the fishery in the recent past and this may have affected the assessment. A cause for concern is the inability of the model to match the inconsistencies between the survey and the commercial catch-at-age data. The estimate of SSB from the survey is considerably higher for 2003/2004 than that obtained from ICA. This is reflected in Figure 4.6.2.9. However ICA has produced relatively consistent outputs in the past two years. In the absence of a fish-eries-independent estimate, the current estimates of recruitment from the assessment should be treated with caution, though they suggest improved recruitment in 1999 and 2001. The strong year effects in the survey and the especially 1998 survey need to be evaluated. A re-examination of the raw data files and echograms from the survey time-series should be carried out.

### 4.7 0Short-term projection

A short-term projection was carried out under the following assumptions. The number of 1 ringers was based on the geometric mean from 1958 to 2001. This is the same procedure as last year and was followed to allow for the inclusion of the period of recruitment failure. This value was 406 million fish, somewhat lower than the value of 504 million fish used last year. Mean weights in the catch and in the stock were calculated as means over the period 1998-2003. Population numbers of 2-ringers in the 2004/2005 season was calculated by the degradation of geometric mean recruitment (1958-2001) following the same procedure as last year.

Two scenarios are presented, one based on $\mathbf{F}_{\mathrm{sq}}\left(=\mathrm{F}_{2003}\right)$, the other on a catch constraint of 13,000 (the TAC for $2004 / 2005$ ). The input data for the prediction based on $\mathbf{F}_{\mathrm{sq}}$ is provided in Table 4.7.1. A single option management table based on $\mathbf{F}_{\mathrm{sq}}=\mathrm{F}_{2003}$ is given in Table 4.7.2. A management option table based on $\mathbf{F}_{\mathrm{sq}}$ in 2003 with options for 2004 is given in Table 4.7.3. Fishing at $\mathbf{F}_{\text {sq }}$ in the 2004/2005 season will produce landings of $15,000 \mathrm{t}$ and an SSB of $41,000 \mathrm{t}$. Continued fishing at this level of F will result in landings of $15,000 \mathrm{t}$ in the 2005/2006 season and the $2006 / 2007$ season. Based on this prediction, SSB is estimated to be about $41,000 \mathrm{t}$ in 2004/2005 and again in $2005 / 2006$, falling slightly to $40,000 \mathrm{t}$ in 2006/2007.

The input data for the prediction based on the TAC constraint $(=13,000 t)$ is provided in Table 4.7.4. A single option management table based on TAC constraint $(=13,000 \mathrm{t})$ is given in Table 4.7.5. A management option table based on TAC constraint $(=13,000 \mathrm{t}$ ) with options for 2004 is given in Table 4.7.6.

If fishing is constrained by a TAC of $13,000 \mathrm{t}$ in 2004/2005, then this will result in an SSB of $43,000 \mathrm{t}$, and fishing mortality will be 0.44 . If this TAC is caught again in 2005/2006, then SSB will reach $45,000 \mathrm{t}$, with a slight reduction in F to about 0.43 .

Plots of yield-per-recruit and short-term yield are given in Figure 4.7.1. $\mathbf{F}_{\max }$ is undefined. $\mathbf{F}_{0.1}$ is defined as 0.1674 , and $\mathrm{F}_{35 \% \mathrm{SPR}}$ is defined as 0.1807 , lower than current mean $\mathrm{F} 2-7$ that is estimated as $0.4708 . \mathrm{F}_{\mathrm{sq}}$ is concomitant with SSB that is close to $\mathbf{B}_{\mathrm{pa}}$. Landings of $13,707 \mathrm{t}$ in 2004/2005 are close to the current TAC and are concomitant with an F of 0.519 , a $10 \%$ increase in $\mathbf{F}_{\mathrm{sq}}$. TAC's in the range 15,000 to 17,000 would require $30 \%$ to $50 \%$ increases in current estimated F .

### 4.8 Quality of the assessment

The landings in this fishery have been monitored rigorously and management measures tightly enforced, resulting in considerably better accuracy in landings figures. Allied to this there is a comprehensive sampling programme of the landings that has been enhanced through co-operation with the industry. Apart from a low sampling rate in VIIj, this provides a relatively sound basis for the catch data in the assessment.

Fishery independent data are provided by the autumn acoustic survey, of which the principle index is the age disaggregated numbers. These data are noisy therefore the index only uses the mid range of the year cases. There are no estimates of recruitment.

The present assessment is essentially an update on the previous year's assessment. In recent years, the assessment has become unstable due to problems with acoustic survey numbers-at-age data and an apparent change in the recruitment levels between 1996 and 1998, which was not detected by the assessments in those years. The uncertainty in the assessment around the mid to late 1990s (partially due to differences in the trends in the acoustic survey and catch data) is reflected in the historical uncertainties (see Figure 4.6.2.9).

### 4.9 Biological reference points

Biological reference points were discussed in detail in the 2000 WG report (ICES 2000/ACFM:10) and in the report of the previous years (ICES 1999/ACFM:12, ICES 1998/ACFM:14). A summary of this discussion was presented in last years HAWG report. $\mathbf{B}_{\mathrm{pa}}$ is currently at $44,000 \mathrm{t}$ and $\mathbf{B}_{\text {lim }}$ at $26,000 \mathrm{t}$ for this stock $\mathbf{F}_{\mathrm{pa}}$ and $\mathbf{F}_{\text {lim }}$ are not defined. The SGPRP (ICES 2003 ACFM :15) has reviewed the methodology for the calculation of biological reference points, and applying a segmented regression to the stock and recruit data from the 2002 HAWG assessment gave a breakpoint at $61,306 \mathrm{t}$. This change point appears to be very high with respect to the historical exploitation of the stock. Given that there is a cluster of observations just above this value the sensitivity of the method to these data needs to be further investigated. The HAWG decided that the first priority for this stock should be to achieve a stable assessment and that once this was done the reference points would be reinvestigated. There is still considerable instability in the assessment, so there is no basis for a revision of reference points at this point.

### 4.10 Management considerations

The current management of this fishery has been described above. The management in place is the best that has ever been implemented for this stock. The working group encourages these initiatives to continue and be intensified. The most important aspects of the suite of management measures have been the shift away from targeting spawners and the closure of box C for two seasons.

The uncertainty in the assessment has been evaluated, but it is still not possible to use this information to produce an analytical TAC. Fishing at current estimated F is expected to lead to an increase in SSB over the coming 3 years. Annual catches of around $13,000 \mathrm{t}$ are concomittitant with $\mathbf{F}_{\mathrm{sq}}$. These estimates of F are uncertain, however. The working group considers that this stock could be a candidate for alternative management strategies, other than TAC. This would imply a change in the type of assessment and advice that are currently produced. An investigation of harvest control rules should be carried out for this stock.

The SSB estimate in the past two years is less uncertain than in previous assessments, however the SSB estimate in the final year is still strongly influenced by recruitment at age and without a recruitment index it is not possible to estimate the current SSB more precisely. For this reason the assessment will remain unstable if recruitment continues to fluctuate. Consequently without a recruitment index, the assessment will stabilise only if recruitment returns to geometric mean values for a number of years. The decrease in uncertainty this year may be an indication that this is beginning
to happen. It is too early to evaluate if the effects of closing box C. However it is considered that this must have had advantageous effects on the stock. The fact that so much of the biomass in the acoustic survey was recorded in this area, and the predominance of younger fish, suggests that this area should be afforded as much protection as possible.

The changing pattern of the fishery has presented difficulties for the assessment model. The working group notes that these management measures are likely reduce fishing mortality and improve the age profile of the stock. In addition, the increased proportions of older fish in the summer fishery indicates that smaller, first time spawners are being less targeted. In a stock where 1 -ringers contribute so much to SSB , this is a good development.

The main Irish fishery takes place on the spawning grounds along the Irish coast. The spawning grounds are well known and are mainly located in shallow inshore waters. In recent years a number of these spawning grounds have come under threat from possible extraction of gravel, dumping of harbour silt and dredge spoil and from the location of fish farms. All relevant information on seabed classification, position of spawning beds and hydrography should be collated so that informed decisions can be made about future proposals for dumping of spoil or gravel extraction.

Table 4.1.3.1 Celtic Sea and Division VIIh, j and k herring landings by calendar year ( t ), 1988-2003. (Data provided by Working Group members.) These figures may not in all cases correspond to the official statistics and cannot be used for management purposes.

| Lowest SSQ is for $\mathrm{F}=0.550$ |  |

No of years for separable analysis : 6
Age range in the analysis : $1 \ldots 9$
Year range in the analysis : $1958 \ldots 2003$
Number of indices of SSB : 0
Number of age-structured indices : 1
Parameters to estimate : 29
Number of observations : 100
Conventional single selection vector model to be fitted.
Survey weighting to be Manual (recommended) or Iterative (M/I) ?-->M
Enter weight for FLT02: Celtic combined acc data (Catch: at age 2--> 1.000000000000000
Enter weight for FLT02: Celtic combined acc data (Catch: at age 3--> 1.000000000000000
Enter weight for FLT02: Celtic combined acc data (Catch: at age 4--> 1.000000000000000
Enter weight for FLT02: Celtic combined acc data (Catch: at age 5--> 1.000000000000000
Enter estimates of the extent to which errors
in the age-structured indices are correlated
across ages. This can be in the range 0 (independence)
to 1 (correlated errors).
Enter value for FLT02: Celtic combined acc data (Catch:--> 5.00000000000000003E-02
Do you want to shrink the final fishing mortality (Y/N) ?-->n
Seeking solution. Please wait.
Aged index weights
FLT02: Celtic combined acc data (Catch:
Age : 2345
Wts : 0.9620 .9620 .9620 .962
$F$ in 2003 at age 3 is 0.464859 in iteration 1
Detailed, Normal or Summary output (D/N/S)-->D
Output page width in characters (e.g. 80..132) ?--> 80
Estimate historical assessment uncertainty ?-->n
Successful exit from ICA

STOCK SUMMARY

No of years for separable analysis : 6
Age range in the analysis : 1 . . . 9
Year range in the analysis : 1958 . . . 2003
Number of indices of SSB : 0
Number of age-structured indices : 1
Parameters to estimate : 29
Number of observations : 100
Conventional single selection vector model to be fitted.

### 5.1 Division VIa(North)

### 5.1.1 ACFM Advice Applicable to 2003 and 2004

ACFM reported in 2003 that the state of the stock remained uncertain although all the indications are that the stock is lightly exploited. Consequently, ACFM recommended that fishing mortality be maintained at status quo ( $=0.21$ ), corresponding to catches in 2004 not exceeding $30,000 \mathrm{t}$.

The agreed TAC for 2004 is $30,000 \mathrm{t}$. The TAC in 2003 was $30,000 \mathrm{t}$.
There are no explicit management objectives for this stock, because of uncertainties about the historical catch data, the size of the biomass, and estimates of recruitment and fishing mortality. A $\mathbf{B}_{\mathrm{lim}}$ of $50,000 \mathrm{t}$ has been proposed for this stock (ICES 2003/ACFM:15).

### 5.1.2 The Fishery

Historically, catches have been taken from this area by three fisheries. The Scottish domestic pair trawl fleet and the Northern Irish fleet operated in shallower, coastal areas, principally fishing in the Minches and around the Island of Barra in the south; younger herring are found in these areas. The Scottish and Norwegian purse seine fleets targeted herring mostly in the northern North Sea, but also operated in the northern part of VIa (N). An international freezertrawler fishery has historically operated in deeper water near the shelf edge where older fish are distributed. These vessels are mostly registered in the Netherlands, Germany, France and England. In recent years the catch of these fleets has become more similar and has been dominated by younger adults resulting from increased recruitment into the stock.

In 2003, the Scottish trawl fleet fished only in very similar areas to the international fishery, and not in the more traditional coastal areas in the southern part of VIa (N). Catch-at-age data this year indicate that the catches are similar in age composition. Only the Irish fleet fished in the southern part of VIa (N) in 2003.

As a result of perceived problems of area misreporting of catch from IVa into VIa (N), Scotland introduced a new fishery regulation in 1997 aiming to improve reporting accuracy. Under this regulation, Scottish vessels fishing for herring are required to hold a license either to fish in the North Sea or in the west of Scotland area (VIa (N)). Only one of these options can be held at any one time.

### 5.1.3 Catches in 2003 and Allocation of Catches to Area

The WG considers that the serious problems with misreporting of catches from this stock, with many examples of vessels operating and landing herring catches distant from VIa (N) but reporting catches from that area, have been reduced in recent years from some $30,000 t$ to around $5,000 t$ in 2002. In the past, fishery-independent information confirmed that large catches were being reported from areas with low abundances of fish, and informal information from the fishery and from other sources confirmed that most catches of fish recorded between $4^{\circ} \mathrm{W}$ and $5^{\circ} \mathrm{W}$ were most probably misreported North Sea catches. The problem was detailed in the Herring Assessment WG report in 2002 (ICES 2002/ACFM:12). Improved information from the fishery in 1998-2002 allowed for re-allocation of many catches due to area misreporting (principally from VIa (N) to IVa (W)). This information was obtained from only some of the fleets. In 2003, for the first time since 1983, observer data indicated there was no misreported catch.

For 2003, the preliminary report of official catches corresponding to the VIa (N) herring stock unit total 28,835 t, compared with the TAC of $30,000 \mathrm{t}$. The Working Group's estimates of area misreported catches are 0 t . No herring has been reported as discarded. Currently, discarding is not perceived to be a problem. An insignificant amount (7t) has been assigned as unallocated catch by the Working Group.

The Working Group's best estimate of removals from the stock in 2003 is $28,835 \mathrm{t}$. Details of estimated national catches from 1983 to 2003 are given in Table 5.1.1.

### 5.1.4 Historic Catches from 1957 to 1975

The working group has obtained preliminary estimates of catch and catch-at-age for the period 1957 to 1975 . These have been estimated from records of catch presented in HAWG reports from 1973, 1974, 1981 and 1982. Intervening reports were also consulted to check for changes or updates during the period. Catch-at-age data were available from 1970 to 1975 from the 1982 Working Group report, and catches-at-age for the period 1957 to 1972 were estimated from paper records of catch-at-age by national fleets for 1957 to 1972, held at FRS Marine Laboratory Aberdeen. The fishing practices of national fleets were established for the period 1970 to 1980 from catches in VIa and VIa (N) recorded in the 1981 and 1982 Working Group reports respectively. This procedure suggested that, on average, more than $90 \%$ of
catch by national fleet could be fully assigned to either VIa (N) or VIa (S). The remaining catch was assigned assuming historic proportions. During this period catches were split into autumn and spring spawning components; anecdotal information on trials to verify this separation suggests it was not a robust procedure. Currently about $5 \%$ of herring in VIa (N) is found to be spent at the time of the acoustic surveys in July, and thought to be spring spawning herring. However, at present the Working Group assesses VIa (N) herring as one stock, regardless of spawning stock affiliation. In the earlier period higher proportions were allocated as spring spawners. The Working Group considered that it was preferable to combine all catch in the earlier period as VIa ( N ) catch, as the spawning components are currently mixed and the historic separation was uncertain. Similarly, a small Moray Firth juvenile fishery was also included in VIa (N) catch in earlier years because it was thought that these juveniles were part of the VIa (N) stock. Separating this component in the historic data was difficult, and as the fishery ceased in the very early 70s this has no implications for current allocation of these fish. The Moray Firth is, geographically, part of IVa (ICES stat. rectangles 44E6, 44E7, 45E6 - see Figure 1.5.1) and is now managed as part of that area. Currently there are no juvenile herring catches from the Moray Firth.

Full details of the analysis carried out is provided as an annex to this report (Annex 1), the estimated catches in tonnes by country are shown in Table 5.1.2 and catches in number-at-age are given in Table 5.1.3.

### 5.2 Biological Composition of Commercial Catches

Age composition data, by country and by quarter, are detailed in Table 5.2.1. The number of samples used to allocate an age-distribution for the VIa (N) catches decreased from 52 in 2002 to 37 in 2003. However, this still exceeds the required one sample per 1,000 tonnes of catch. Comparison of the age structure of the German, Netherlands, and Scottish samples indicated that there was little difference in the age structure of the catch for these fleets in 2003.

Unsampled catches were allocated a mean age-structure (weighted by the sampled catch) of either the Scottish, or the German/Netherlands sampled fleets in the same quarter, or in adjacent quarters if no samples were available in the corresponding quarter. If no sampling data were available for a quarter, a mean age-structure of all samples from adjacent quarters was used. The allocation of age structures to unsampled catches, and the calculation of total international catch-at-age and mean weight-at-age in the catches were made using the 'sallocl' programme (Patterson, 1998).

Catch in number-at-age information is given in Table 5.2.2.
In the past concern has been raised over the quality of sampling of commercial catch. It was suggested in the 2001 ACFM technical minutes that an analysis of catch by quarter and country might shed some light on the variability in the catch information. In practice the fishery is often dominated by a single quarter catch, and a single country dominates sampling. Thus such an analysis is impossible. In 2002 the Working Group conducted an extensive analysis of the sensitivity of the assessment to missing catch information (Section 5.1.12 in ICES 2002/ACFM:12).

### 5.3 Fishery-independent Information

### 5.3.1 Acoustic Survey

The 2003 acoustic survey was carried out from 1-20 July using a chartered commercial fishing vessel (MFV Enterprise). The total biomass estimate obtained was higher than in the previous year $(739,200 \mathrm{t}$ this year compared to $548,800 \mathrm{t}$ in 2002), and is the second highest in the survey time-series. Biomass estimated from the acoustic survey tends to be noisy and similar fluctuations have been observed in previous years. Herring were found in areas similar to those in 2002, namely south of the Hebrides off Barra Head, west of the Hebrides and along the shelf edge. However, the centre of the southern Hebrides distribution was more northerly than in previous years. Further details are available in the Report of the Planning Group for Herring Surveys (ICES 2004/G:05). Estimates of abundance by age and in aggregate spawning stock biomass for 2003 and for previous years are given in Table 5.3.1.

### 5.4 Mean Weight-at-age and Maturity-at-age

### 5.4.1 Mean Weight-at-age

Weights-at-age in the catches and weights-at-age in the stock from acoustic surveys are given in Table 5.4.1. The weights-at-age in the stock appear to be higher than the long-term mean for 1-ringers but slightly lower than the longterm mean across the rest of the age range.

Catch weights-at-age for 2003 are generally lower than the long-term average, except for 2-and $9+$ ring herring.

### 5.4.2 Maturity Ogive

The maturity ogive is obtained from the acoustic survey (Table 5.4.2).
ACFM commented in 2002 that unlike in other years when maturity and size-at-age were correlated, in 2001 ma-turity-at-age increased and weight-at-age decreased. In 2003, maturity-at-age is lower than in 2002, but still higher than the mean of the series for 2 -ringers. Weights-at-age in the catch show no consistent trend. Weights-at-age in the stock
are generally lower than in 2002. However, in the 2003 Working Group, examination of the relationship between weight-at-age and proportion mature showed no relationship between the two.

### 5.5 Recruitment

There are no specific recruitment indices for this stock. Although both catch and acoustic survey have catches-at-age 1ring both the fishery and survey encounter this age only incidentally. The first reliable appearance of a cohort appears at 2 -ring in both the catch and the stock. Thus in predictions, estimates of both 1-and 2-ring herring numbers from the assessment need to be replaced for prediction years.

### 5.6 Stock Assessment

### 5.6.1 Data Exploration and Preliminary Modelling

As last year, an exploratory assessment of the stock was carried out by fitting an integrated catch-at-age model (ICA version 1.4w described in the methods section in the 2003 Working Group report (ICES 2003/ACFM: 17, Section 1.6.1)). An age-structured index was available from the acoustic survey from 1987, 1991-1996 and 1998-2003 (Section 5.3.1).

This year the catch data for this stock were extended back to 1957 (refer to Section 5.1.4 and Annex 1). ICA was run on this extended data set with the same settings as in the 2003 Working Group (i.e., an eight year separable period with 1 -ringers in the catch and survey down-weighted). This confirmed that the addition of the extended data set did not alter the perception of the status of the stock when compared to the 2003 assessment of the stock for the years 19762002. One concern for the stock assessment for the data extension period was that the selection on older age classes might have been different in history. The current assessment settings fix the selection on older ages ( 8 and $9+$ ) equal to the selection at age 4 in the separable period. If the historical selection departed from this assumption then it would violate the assumptions in ICA used for production of the plus group in the historic part of the assessment. For the period 1980-2003, after the VIa (N) fishery closure, the depletion of age classes in the catches appeared constant across age (Figure 5.6.1), suggesting that fixing $S$ at 1 for the older ages is appropriate. For part of the period prior to, and during, the closure (1970-1979) depletion across ages was variable, which might introduce some small errors into the estimate of numbers in the older ages in that period. However, it is only a relatively short period within the whole timeseries. The assessment using the extended data set was therefore considered acceptable.

An examination of log catch ratios over the extended time-series 1957-2003 was carried out and showed no obvious trends in the exploitation patterns over time. As last year, there were no clear trends in exploitation patterns between ages or over years in the shorter time-series 1981 to present (Figure 5.6.2).

ICA was then run for the whole time-series, 1957-2003, (2004 assessment) to compare the model fit for this year with the 2003 Working Group assessment.

The residual patterns for the two runs are very similar (Figure 5.6.3). The surface plot is consistent and the year residuals follow the same pattern. The age residuals are different, with a relatively larger value for 8 -ringers this year. However, the age residuals values are very small.

The selection pattern for the 2004 assessment is essentially identical to last year's assessment (Figure 5.6.4).

### 5.6.2 Stock Assessment

This essentially is an update assessment using the same settings as in 2003.
Assessment of the stock was carried out by fitting an integrated catch-at-age model (ICA version 1.4 w ). The model settings are the same as for 2003. The run log for the assessment is shown in Table 5.6.1. The period for the separable constraint is 8 years. The catch and survey data were down-weighted for 1-ring herring (see the 2001 Working Group assessment report (ICES 2001/ACFM:12)). The input data are given in Tables 5.6.2 to 5.6.8. The output data are given in Tables 5.6.9 to 5.6.18. The assessment results in an SSB for 2003 of $162,000 \mathrm{t}$ and a mean fishing mortality ( $3-6$ ringers) of 0.19 (Table 5.6.14). The model diagnostics (Tables 5.6.13 to 5.6.18 and Figures 5.6.6 to 5.6.16) show that the total residuals by age and year between the catch and the separable model are reasonably trendfree and small. The acoustic survey age and year residuals patterns are trend-free. The acoustic survey residuals are of similar magnitude to the catch model residuals but show more evidence of year effects. The current estimate of SSB shows a small decrease in biomass from 174,000 $t$ in 2002 to $162,000 \mathrm{t}$ in 2003. This is still above the estimate for $2001(152,000 \mathrm{t})$. However, these estimates for 2001 and 2002 in the current assessment have been revised upwards from last year's assessment. The large recruitment of 1-ringers to the population in 2001 is still seen as a peak in numbers of 4-ringers in 2003 (the 1998 year class) in both the catch and acoustic survey data. The 2000 year class is abundant in the acoustic survey (the most abundant 2-ringer value since the 1995 survey). The 1999 year class is more dominant in the catch. Table 5.6 .14 shows that the assessment model estimates similar values of recruitment for the 1999 and 2000 year classes.

The assessment shows a relatively stable SSB over the last three years, substantially higher than the previous ten years. Fishing mortality has stabilised at a low level.

The inclusion of the extended time-series in the assessment shows that the productivity in the period prior to the closure (1957-1979) was markedly higher.

Figure 5.6 .17 shows the trajectories of $5,25,50,75$ and 95 percentiles from the estimates of historical uncertainty of F, SSB and recruits produced in the final assessment. These are based on 1000 bootstrapped samples of residuals. Uncertainty in the 2004 Working Group assessment is comparable to that in the 2003 Working Group assessment. In 2003 uncertainty was found to be considerably reduced from previous years (ICES 2003/ACFM:17), reflecting the stability of the input data over the final two or three years to that date. The greatest uncertainty in F is in 1997/98 when catch data were poorly sampled due to area misreporting that has now largely ceased.

### 5.7 Projections

### 5.7.1 Deterministic short-term projections

One scenario for deterministic short-term projections is presented: status quo F for 2004. This is consistent with both the current fishery and the level of catch that matches the TAC. Multiple options tables are available for 2005 (Table 5.7.3).

Short-term projections were carried out using MFDP. Input data are stock numbers on $1^{\text {st }}$ January in 2004 from the 2004 ICA assessment (Section 5.6, Table 5.6.11), with geometric mean replacing recruitment at 1 - and 2 -ring in 2004 and 1 -ring in 2003. The retrospective assessment of recruitment in the 2003 Working Group (ICES
2003/ACFM:17) showed the substantial revision of 1- and 2-ring herring abundance in subsequent assessments, justifying the use of geometric means for these ages. The selection pattern used is as estimated by ICA (Table 5.6.13). For the projections, data for maturity, natural mortality, mean weights-at-age in the catch and in the stock are means of the three previous years (i.e., 2001-2003) (Table 5.7.1). An example of a short-term projection is shown in the text table below, illustrating that at status quo F catches can be expected to be stable at around $30,000 \mathrm{t}$.

| Scenario | 2004 | 2005 | 2006 |
| :--- | :--- | :--- | :--- |
| $1-$ status quo F | $\mathrm{F}_{2000}=\mathrm{F}_{2003}=0.19$ | $\mathrm{~F}_{2005}=\mathrm{F}_{2003}=0.19$ | $\mathrm{~F}_{2006}=\mathrm{F}_{2003}=0.19$ |
|  | Status quo F | Status quo F | Status quo F |
|  | Catch $=29,797 \mathrm{t}$ | Catch $=30,116 \mathrm{t}$ | Catch $=30,691 \mathrm{t}$ |

The results of the short-term projections can be seen in Tables 5.7.2-5.7.3. Table 5.7.2 shows single option predictions for 2005 and 2006. Table 5.7 .3 shows the multiple options for 2005 . The short-term forecast for landings and SSB at status quo F is shown in Figure 5.7.2. SSB remains at about $170,000 \mathrm{t}$ in the short-term. A catch constraint option was not considered as a scenario as the status quo F projection gives catches in the short-term around the current TAC, 30,000 t.

### 5.7.2 Yield-per-recruit

A yield-per-recruit analysis was carried out using MFYPR to provide a yield-per-recruit plot for VIa (N) (Figure 5.7.2). The values for $\mathbf{F}_{0.1}$ and $\mathbf{F}_{\text {med }}$ are 0.16 and 0.28 respectively. These may be compared with the current F ( 2004 assessment) of 0.19 . The yield-per-recruit relationship starting from the same year as last year, suggests that at geometric mean recruitment ( 927 million for the period 1976-2002) a yield of approximately $29,000 \mathrm{t}$ is possible at $\mathbf{F}_{0.1}$ and approximately $33,300 \mathrm{t}$ is possible at $\mathbf{F}_{\text {med }}=0.28$.

### 5.7.3 Stochastic medium-term projections

No biological reference points are currently available for this stock, although a value for $\mathbf{B}_{\text {lim }}$ of $50,000 \mathrm{t}$ has been proposed by the SGPRP (ICES 2003/ACFM:15). In the 2003 Working Group a value for $\mathbf{B}_{\mathrm{pa}}$ was put forward (section 5.8 in ICES 2003/ACFM:17) and is discussed further below in section 5.8. The suggested $\mathbf{B}_{\mathrm{pa}}$ value is used here to provide a value against which the stock trajectory in the medium-term projections can be measured.

Three sets of medium-term projections were carried out on the basis of (i) exploitation at status quo F, (ii) exploitation at status quo $\mathrm{F} * 1.35$ and (iii) a catch of $40,000 \mathrm{t}$ in 2005 onwards. The method used to calculate medium-term projections was that described in ICES 1996/ACFM:10 using the program ICP. Weights-at-age in the catch were calculated as the mean weights-at-age from 2001-2003. Weights-at-age in the stock, maturity ogives and natural mortality were as given in Section 5.6.2. Geometric mean recruitment for 1- and 2-ringers was used to replace the values in the assessment for 2004, however, the covariance values produced by ICA were retained. The stock-recruit relationship used in the medium-term projection was the Ockham option using the converged VPA 1972 to 2000 (Figure 5.7.3.1). Figure 5.7.3.2 shows a comparison between the cumulative distribution of recruitment from the assessment and the simulated recruitment in ICP. The agreement is good, and the arithmetic mean of the observed recruitment was 5\% higher than the simulated recruitment. The input parameters are summarised in Table 5.7.4 and the run log is given in Table 5.7.5. Three scenarios are presented, based on the assessment using the eight-year separable period (Figure 5.7.3.3). The scenarios are chosen to provide status quo F exploitation, and a fixed F ( $\mathrm{F}=1.35^{*}$ Fstatus quo) or fixed TAC exploitation ( $40,000 \mathrm{t}$ ) to provide a more or less stable stock.

The results of the stochastic medium-term projection are given in Figure 5.7.3.3 and summarised in the text table below. For the status quo F scenario, given a constant F exploitation pattern, catches and SSB both rise gently and stabilise to Landings of $34,000 \mathrm{t}$ and SSB of $190,000 \mathrm{t}$. For status quo $\mathrm{F} * 1.35$ (equivalent to $\mathrm{F}=0.25$ ), catches rise in 2006 to around $38,000 t$ and, with some fluctuation, stabilise around $38,000 t$ in the medium-term. SSB rises to around $150,000 \mathrm{t}$ in 2008 and remains there in the medium-term. The third scenario (a catch of $40,000 \mathrm{t}$ in 2005 onwards) shows a stable SSB of around $145,000 \mathrm{t}$ from 2004 across the medium-term. The risk of SSB falling below $\mathbf{B}_{\mathrm{lim}}$ or suggested $\mathbf{B}_{\mathrm{pa}}$, and the SSB in year $10(2013)$, is given in the text table below.

|  | Status quo F (F=0.19) | status quo F * 1.35 | a catch of $40,000 \mathrm{t}$ in 2005 on- <br> wards |
| :---: | :---: | :---: | :---: |
| Average Yield | $31,027 \mathrm{t}$ | $35,579 \mathrm{t}$ | $39,000 \mathrm{t}$ |
| SSB in 2013 | $190,000 \mathrm{t}$ | $154,000 \mathrm{t}$ | $146,000 \mathrm{t}$ |
| Risk of stock falling <br> below suggested $\mathbf{B}_{\mathrm{lim}}$ | $0.1 \%$ | $0.4 \%$ | Increasing to $7 \%$ by 2013 |
| Risk of stock falling <br> below suggested $\mathbf{B}_{\mathrm{pa}}$ | $0.7 \%$ | $4 \%$ | Increasing from $5 \%$ in 2004 to <br> $15 \%$ in 2013 |

### 5.8 Reference Points

The report of SGPRP (ICES 2003/ACFM:15) proposed a $\mathbf{B}_{\lim }$ of 50,000 t for VIa (N) herring. This is calculated from the values in the converged part of the VPA (1976-1999) and the Working Group endorsed this value last year.

In 2003 the Working Group estimated retrospective error in terminal SSB from 4 years and gave a mean of the absolute values of $20 \%$ and a maximum of $38 \%$. Since there are so few data points and they are close in time to the current year the maximum value might be an underestimate of the range of values. The Working Group felt that the $90^{\text {th }}$ percentile on a normal distribution that had a mean error of $20 \%$ might be a more appropriate measure; this would give a factor close to $50 \%$.

$$
\mathbf{B}_{\mathrm{pa}}=\mathbf{B}_{\mathrm{lim}} * 1.50 \text { and gives } \mathbf{B}_{\mathrm{pa}}=75,000 \mathrm{t}
$$

The Working Group had considerable trouble developing F reference points but proposed a value based on rather limited data on errors of estimation. $\mathbf{F}_{\text {lim }}$ was derived directly from the equilibrium exploitation rate for an SSB for $\mathbf{B}_{\text {lim }}$. $\mathbf{F}_{\mathrm{pa}}$ was obtained in a similar manner to $\mathbf{B}_{\mathrm{pa}}$ with a factor of $50 \%$. Full details of the method are given in last year's Working Group report.

ACFM had expressed concern with the proposed reference points from the 2003 Working Group, did not endorse them and was concerned about F reference points in particular. They noted that the analyses produce a high $\mathbf{F}_{\text {lim }}$ because there have been good recruitments at low SSB, hence the slope of the segmented regression is very steep, compared to other herring stocks. The ACFM decided that it would like the assessment Working Group to advise if there are biological reasons for expecting the atypically high productivity at low SSB. It was also noted that the lowest observed SSBs, with associated high recruitments, are at beginning of the time-series. ACFM asked the Working Group to consider how reliable the catch data were in those years, and if some of the catch may have been taken in the North Sea. Hence these apparent high productivities could be either immigration or misreporting into the area from the North Sea.

The Working Group examined the time-series of stock and recruitment and found that the ACFM subgroup had interpreted the data inconsistently because the recruitment was presented at 1 -ring for autumn spawners and thus required a shift of 2 years to obtain the stock-recruit relationship. The highest recruitment had therefore occurred at mid-range biomass for the period 1976 to 2002, and not at the lower biomasses early in that period. In order to examine the productivity of the stock, data archives at FRS Marine Lab in Aberdeen were examined for data from this period and earlier, back to 1957 (see section 5.1.4 and Annex 1). John Morrison (who had been involved in data collection and the HAWG in the early 70s and dealt with the data at the time) was consulted about the validity of the data. His opinion was that the fishery had indeed moved to the west of Scotland, even before the closure of the North Sea fishery. There is a possibility of immigration but the six highest recruitments in the longer time-series do not coincide with the six highest in the North Sea, suggesting some considerable independence. The early data showed two very strong year classes (1963 and 1969) which do not occur in the North Sea.

A preliminary examination of the longer time-series suggests a period before 1970 with higher stock productivity and higher biomass. The 2004 assessment indicates that the stock has been exploited at a relatively low level for the last 20 years ( F bar less than 0.30 ). Despite this relatively low exploitation rate the stock has failed to exceed its current level of $160,000 t$, though it has reach this level twice since 1976. When the stock was at these higher levels fishing mortality was lower than the mean but further expansion of the stock did not occur. The Working Group did not manage to complete an analysis of the longer time-series to fully investigate the potential yield and suitable limit and reference points.

The Working Group is satisfied that the recruitment seen in the period 1976 to 2003 is correct and not atypical for this stock, and that the $\mathbf{B}_{\mathrm{lim}}$ of $50,0000 \mathrm{t}$ derived from this period is consistent with the productivity seen.

The Working Group is unable to establish if there are environmental reasons that might explain a change in productivity between the periods $1957-1975$ and 1976 - 2000. In conclusion the WG considers that the reference points
suggested last year are consistent with the stock summary from 1976 to 2000 when the productivity and yield are lower and might be considered conservative.

The Working Group did not repeat the extensive analysis carried out last year but suggests that, at the very least, a $\mathbf{B}_{\text {lim }}$ of $50,000 \mathrm{t}$ and a $\mathbf{B}_{\mathrm{pa}}$ of $75,000 \mathrm{t}$ are suitable as Biomass limit and reference points for VIa (N). Reference points are urgently needed for the management of this stock and these values are based on a converged part of the VPA so should not change and are as well founded as many others currently in use.

## Suggested Precautionary Approach reference points:

| $\mathbf{B}_{\text {lim }}$ is $50,000 \mathrm{t}$ | $\mathbf{B}_{\mathrm{pa}}$ be set at $75,000 \mathrm{t}$ |
| :--- | :--- |
| $\mathbf{F}_{\text {lim }}$ is 0.75 | $\mathbf{F}_{\mathrm{pa}}=0.35$ |

Technical basis:

| $\mathbf{B}_{\text {lim }}: \mathbf{B}_{\text {loss }}$ Estimated SSB for sustained recruitment | $\mathbf{B}_{\mathrm{pa}}:=1.5 * \mathbf{B}_{\text {lim }}$ |
| :--- | :--- |
| $\mathbf{F}_{\text {lim }}$ corresponding to <br> 0.75 $\mathbf{B}_{\text {lim }}$ from the yield-per-recruit $\mathbf{F}_{\text {lim }}=$ | $\mathbf{F}_{\mathrm{pa}}=0.5 * \mathbf{B}_{\text {lim }}$ |

### 5.9 Quality of the assessment

There was concern in the late 1990s about the retrospective error in the assessment, in particular sensitivity to poor sampling of catch. The sensitivity of the model to the catch was explored by examining the influence of groups of catch numbers-at-age on the assessment. It was concluded that these did not have a major influence on the perception of the state of the stock. The current sampling levels are much improved (Table 5.2.1). The addition of the new data to the beginning of the time-series has not changed the recent perception of the stock in the assessment. The 2002 and 2003 Working Groups inspected a number of possible sources of model uncertainty, including sensitivity to choice of length of separable period and sensitivity to a small number of isolated large cohort estimates in the Acoustic survey. They suggested that despite the large noise in the signals, the assessment was consistent and credible, although the choice of the length of the separable period was an important consideration in maintaining consistency.

Retrospective analyses of the assessment from 1999 to 2003 were carried out. Figure 5.9.1 shows the $\mathrm{F}_{3-6}$ and SSB from ICA assessments with an 8-year separable period for assessments in 2001 to 2003, 7 years in 2000 and 6 years in 1999. The separable period is reduced from 8 to 6 years to exclude catch in 1993 that appears to have a different selection (see section 5.6.1 in last year's Working Group report, ICES 2003/ACFM:17). These retrospective analyses show rather stable estimation of $F$ but more variable estimates of SSB. It is important to note that the assessment is currently underestimating SSB, and SSB is revised upwards with the addition of the extra year's data.

Analysis of the analytical retrospective for each cohort shows a high degree of stability (Figure 5.9.2). In some years the estimates of 1- and 2-ring fish abundance is unstable (e.g. 1997 and 1999). The 1-ringers are down-weighted in the assessment and the 1 - and 2-ringer estimates are not used in the projections (where geometric mean values are used). However it is obvious that the estimations of cohorts after 2-ring are very stable. The retrospective analysis indicates that the problems (raised over the last few years) in estimating catch-at-age in both 1997 and 1998 are now causing little influence to the current assessment.

The current assessment seems very robust for estimation of F , although it gives a less precise estimate of SSB. However there now appears to be much greater stability in the assessment compared to 5-7 years ago and the assumptions used in the ICA model are credible and consistent with the information given in the catch and biological data.

### 5.10 Clyde herring

### 5.10.1 Advice and management applicable to 2003 and 2004

Management of herring in the Clyde is complicated by the presence of two stocks that are not separated currently; a resident spring-spawning population and the immigrant autumn-spawning component. Management strategies have been directed towards rebuilding the highly depleted spring-spawning component to historical levels.

The measures which remain in force in order to protect the indigenous spring-spawning stock are:

- A complete ban on herring fishing from 1 January to 30 April;
- A complete ban on all forms of active fishing from 1 February to 1 April, on the Ballantrae Bank spawning grounds, to protect the demersal spawn and prevent disturbance of the spawning shoals;
- A ban on herring fishing between 00:00 Saturday morning and 24:00 Sunday night;
- The TACs in 2003 and 2004 were maintained at the same level as in recent years (1,000 tonnes).

### 5.10.2

Annual landings from 1955 to 2003 are presented in Table 5.10.1. Landings in 2003 were 328 t . The proportions of spring and autumn spawners in these landings could not be estimated. The sampling levels of the local fishery have been reduced in recent years (Table 5.10.2). In 2003, one sample of Clyde herring was taken.

### 5.10.3 Weight-at-age and stock composition

The catch in numbers-at-age for the period 1970 to 2003 is given in Table 5.10.3. Weights-at-age are given in Table 5.10.4. Mean weights in the stock have not been available from research vessel surveys since 1991, therefore the weights in the stock used are the weights-at-age in the catches. No data were available for 2002 as no samples were taken then.

### 5.10.4 Fishery-independent information

There were no surveys carried out in 2003. Historical estimates from these surveys are tabulated in (ICES 1995/ACFM:13).

### 5.10.5 Stock Assessment

The structure of the stock in the Clyde remains uncertain. No survey data are available from recent years therefore no assessment could be attempted.

### 5.10.6 Stock and catch projections

In the absence of an analytical assessment no stock projections can be provided.

### 5.11 Management Considerations

### 5.11.1 VIa (N) Management Considerations

In the 1990s management of this stock was complicated by area misreporting from area IVa in particular. Due to changes in the fishery and some management changes (in particular VMS) area misreporting into VIa ( N ) has declined from a high of $30,000 t$ in the mid 1990 s to $5000 t$ in 2002. It was estimated at effectively zero in 2003. This will considerably improve the possibilities for sound management.

The assessment presented here is more certain than those from the mid-1990s due to the improvements in the quality of the catch-at-age input data and the longer time-series for the acoustic survey. Current $\mathrm{F}_{3-6}$ is thought to be below 0.2 and SSB at $160,000 t$ is well above the suggested $\boldsymbol{B}_{\mathrm{pa}}$ of $75,000 \mathrm{t}$. Though the SSB is more uncertain than $\mathrm{F}_{3-6}$, this assessment provides a sound basis for assuming that the stock is currently lightly exploited and able to sustain the current fishery. The yield-per-recruit and the short-term and medium-term projections all indicate that a fishery at the same or slightly higher level is sustainable, with only limited risk of the stock falling below the suggested $\mathbf{B}_{\text {pa }}$ in the medium-term. Indications from the medium-term projections suggest that exploitation at $\mathrm{F}=0.25(38,000 \mathrm{t})$ in 2006 is sustainable. It provides a higher yield and a stable, or slightly increasing, stock in the medium-term with minimal risk of falling below $\mathbf{B}_{\mathrm{pa}}$. Exploitation at a fixed exploitation rate of $40,000 \mathrm{t}$ is more risky; although this gives a higher me-dium-term yield, it gives an increased risk of SSB being below suggested $\mathbf{B}_{\text {lim }}$ and $\mathbf{B}_{\mathrm{pa} .}$, because it precludes management response to possible reduced SSB.

### 5.11.2 Clyde herring Management Considerations

The management of this fishery is made difficult by the presence of a mixture of a severely depleted spring-spawning component and autumn spawners from Division VIa. The management objectives for these two components are necessarily distinct. The absence of fishery-independent data from surveys further compounds the problem. Historically the spring-spawning stock supported a fishery with catches up to $15,000 \mathrm{t}$ per year in the 1960 's. Landings began to decline through the 1970's and 1980's. In 1991 there was a dramatic drop in both landings and effort and since then landings have fluctuated at, or more usually below, $1,000 \mathrm{t}$.

In the absence of surveys and with no stock separation of the catches, nothing is currently known about the state of the spring-spawning stock. All the management measures, currently in force, need to remain. Catches should remain at the current low level until more is known about the dynamics of this stock.

Table 5.1.1 Herring in VIa (N). Catch in tonnes by country, 1983-2003. These figures do not in all cases correspond to the official statistics and cannot be used for management purposes.

Table 5.6.14. Herring in VIa(N). Stock summary. N.B. In this table "age" refers to number of rings (winter rings in the otolith.

STOCK SUMMARY

No of years for separable analysis : 8
Age range in the analysis : 1 . . . 9
Year range in the analysis : 1957 . . . 2003
Number of indices of SSB : 0
Number of age-structured indices : 1
Parameters to estimate : 38
Number of observations : 181
Conventional single selection vector model to be fitted.

Table 5.6.15. Herring in $\mathrm{VIa}(\mathrm{N})$. Parameter estimates. N.B. In this table "age" refers to number of rings (winter rings in the otolith.

Table 5.7.1. Herring in $\operatorname{VIa}(\mathrm{N})$. Input data for short-term predictions, numbers-at-age from the assessment with ages 1 and 2 replaced by geometric mean values - natural mortality (M), proportion mature (Mat), proportion of fishing mortality prior to spawning (PF), proportion of natural mortality prior to spawning (PM), mean weights-at-age in the stock (SWt), selection pattern (Sel), mean weights-at-age in the catch (CWt). All biological data are taken as mean of the last 3 years. VIa(N) herring appears to have considerable annual variability in mean weights and in fraction mature. Last years values are not applicable. N.B. In this table "age" refers to number of rings (winter rings in the otolith).

                        K.R. Patterson
SOAEFD Marine Laboratory
                                    Aberdeen
Written December }1997\mathrm{ for ICA v1.4 w
    Revision March 1999
```

```
    Enter Random-Number seed--> 120
    Enter the no. of years between spawning and recruitment at age--> 1
    Change any of the populations (Y/N) ?-->y
    Enter Year, Age, new Population: -1,-1,-1 to finish 2003 1 9.2731400000000000E+05
    Enter Year, Age, new Population: -1,-1,-1 to finish 2003 2 3.3913000000000000E+05
    Enter Year, Age, new Population: -1,-1,-1 to finish -1 -1 -1.000000000000000
    New parameters: index, new value (-1,-1 to finish) -1 -1.000000000000000
    Enter the name of the projection file -->fmult.dat
    Could not access the file. Another name ? -->fmult.dat
Population parameters for the projections are set by taking a mean over a
number of the last years of the data set.
    Use mean natural mortality from 2003 back to--> 2001
    Use mean maturity ogive from 2003 back to--> 2001
    Use mean weight-at-age in the stock from 2003 back to--> 2001
    Enter the reference spawning stock size (e.g. MBAL, Bpa)--> 7.50000000000000000E+04
    Enter the maximum allowable F-multiplier--> 10.000000000000000
Choose type of stock recruit relation :
S - Shepherd R = a.SSB/(1+SSB/b)^c
B - Beverton-Holt R = a.SSB/(1+SSB/b)
R - Ricker R = a.SSB.exp(-b.SSB)
O - Ockham R = GM over observed SSB range
    then linear to origin
N - None R = Historic Geometric Mean R
    Enter your choice (S/B/R/O/N) ?-->0
    Enter first year of data for stock-recruit model--> }197
    Enter last year of data for stock-recruit model--> 2000
    Autocorrelated or Independent errors (I/A)-->i
    Use ICA or SRR (I/S) model value for recruitment in 2003-->i
    Use ICA or SRR (I/S) model value for recruitment in 2004-->i
    Use default percentiles (Y/N) ?-->y
    Use ICA-derived resamples ?-->y
```

Table 5.10.1

## 6 Herring in Divisions VIa (South) and VIIb,c

### 6.1 The fishery

The TAC for this area for 2003 was $14,000 \mathrm{t}$. This was the same TAC as in the previous three years. For 2004 ICES advised that catches should not exceed $14,000 \mathrm{t}$. In 2003 ACFM considered the state of the stock to be unknown with respect to safe biological limits because estimates of SSB and fishing mortality were highly uncertain over the previous $2-3$ years. The current SSB is unknown but is likely to be below $\mathbf{B}_{\mathrm{pa}}(110,000 \mathrm{t})$. For $\operatorname{SSB}$ to be above $\mathbf{B}_{\text {lim }}(81,000 \mathrm{t})$ there would have to have been very strong recruitment in recent years but no evidence has been found for such year classes. F appears to have risen sharply during the late 1990s and although management measures since then have reduced $F$, the current $F$ is unknown. Catches in the last three years have been the lowest observed due to restrictive TACs and the disincentive of poor market conditions.

In 2000 the Irish North West Pelagic Management Committee was established to deal with the management of this stock. The committee has the following objectives:

- To rebuild this stock to above the $\mathbf{B}_{\mathrm{pa}}$ level of $110,000 \mathrm{t}$.
- In the event of the stock remaining below this level, additional conservation measures will need to be implemented.
- In the longer term it is the policy of the committee to further rebuild the stock to the level at which it can sustain annual catches of around $25,000 \mathrm{t}$.
- Implement a closed season from March to October.
- Regulate effort further through boat quotas allocated on a weekly basis in the open season.

This committee manages the whole fishery for this stock at present, given that Ireland currently accounts for the entire catch.

### 6.1.1 Catches in 2003

The main working group landings from this fishery in 2003 are given in Table 6.1.2.1. Misreporting has decreased significantly in recent years and is now well below $1,000 \mathrm{t}$, though there may be some area misreporting from VIaS to VIaN. The total catch recorded for 2003 was around $13,000 \mathrm{t}$, about the same as last year. This figure is down over $1,000 \mathrm{t}$ on the total for 2000. There has been a strong decline in landings from about $38,000 \mathrm{t}$ in 1998. The main reason for the decrease in the total catch was a decrease in the quota, coupled with the decrease in misreported catches. There were no unallocated catches in 2003.

The catches and landings recorded by each country fishing in this area from 1988-2003 are shown in Table 6.1.2.1 and the total catches from 1970 to 2003 are shown in Figure 6.1.2.1. There were no estimates of discards reported for 2003 and there are no indications that discarding is a major problem in this fishery.

### 6.1.2 The fishery in 2003

The number of Irish vessels that participated in the fishery was the same as in recent years. There are two fleet components targeting this stock, large RSW vessels, and smaller dry-hold polyvalent vessels. Both types of vessels work mainly out of the port of Killybegs. Herring are mostly taken opportunistically, by boats targeting scad and mackerel. The dry-hold vessels, however, do direct effort at herring at some times of the year, when not fishing demersal species. About twenty vessels participated in the fishery in 2003/2004. These included small vessels of less than 25 m and RSW vessels greater than 50 m in length. Some of the larger RSW boats did not catch their quota in 2003, opting instead to fish for mackerel. Landings were reported from the end of October until the last week in February. Peak landings were reported in the last few weeks of 2003 and the first few weeks of 2004. Landings were concentrated around the northern boundary of VIIb along the north Connacht coast, the southern boundary of ICES division VIa south around Donegal Bay, and off Co. Donegal from off Tory Island to Malin Head. These locations are shown in Figure 6.1.3.1. The pattern of this fishery has changed over time. In the early part of the $20^{\text {th }}$ Century the main spawning components were the winter spawners on the, off Co. Donegal, and this was where the main fishery took place. In the 1970's and 1980's the west of Ireland autumn spawning components were dominant and the fishery was mainly distributed along west Connaght, in Counties Galway and Mayo. More recently the northern grounds are more important again, and this is reflected in the much smaller catches in VIIb, being less than $1,000 \mathrm{t}$ in the first quarter and less than $1,400 \mathrm{t}$ in quarter 4.

Fish caught in the first quarter had a wider length distribution, and tend to be larger than fish caught at the end of the year (Table 6.1.2.2). A particular aspect of the first quarter fishery in VIa $S$ has been the appearance of large fish off the north Ulster coast in February. These fish are usually over 31 cm TL.

### 6.2.1 Catch in numbers-at-age

The catches-at-age for this fishery since 1970 are shown in Table 6.2.1.1. In recent years the catches in numbers-at-age have been derived mainly from Irish sampling data. Dominant year classes are represented by the 2 and 3 ringers as was the case in 2002 , accounting for $31 \%$ and $27 \%$ respectively. The numbers of 4 -ringers has increased since 2002 , and there was slight increase in the number of 5 and 6 ringers appearing in the commercial catches since 2002 (Figure 6.3.2.3). A decrease in the catches of older fish may be due to a increased targeting of mackerel in the first quarter of 2003.

### 6.2.2 Quality of the catch and biological data

The management of the Irish fishery in recent years has tightened considerably and the accuracy of reported catches in recent years is believed to have improved. The numbers of samples and the biological data are shown in Table 6.2.2.1. The length distributions of the catches taken per quarter by the Irish fleet, are shown in Table 6.1.2.2. The level of sampling was well up on 2002 levels. There is a need, however, to achieve a better coverage of VIIb, especially in the first quarter.

### 6.3 Fishery Independent Information

### 6.3.1 Ground Fish Surveys

Ground fish surveys have been carried out during November along the west coast of Ireland since 1993. More than 60 stations have been sampled each year with a bottom trawl fitted with fine mesh liner. Although these surveys are designed to obtain an abundance index for demersal fish it is hoped that they will also provide recruitment indices for herring. These surveys were conducted using a number of different commercial vessels over the time-series, and this along with the lack of attention paid to herring, may preclude its being used as recruit indices for this stock.

### 6.3.2 Acoustic Surveys

Acoustic surveys were carried out on this stock during the period 1994-1996, targeting fish in their summer feeding phase. A description of acoustic surveys in this area is presented in Table 6.3.2.1. The references cited are dealt with by O'Donnell et al. (in prep.).

In February 2003, a survey was carried out on the winter spawning component of the stock in VIa(S) and VIIb-c The survey track and NASC values from this survey are shown in Figure 6.3.2.1 and Figure 6.3.2.2. No autumn survey was carried out in 2003. In January 2004 a survey was carried out on the winter-spawning component of this stock for 2004 onboard the Celtic Explorer. The results will be available to the group in March 2005. It was felt that the timing of the survey did not coincide with the peak spawning for this component. Therefore it was considered that the stock was not contained in the survey area. Fishing success was reasonably good, although the majority of the estimate was attributed to "herring in a mixture" and "probably herring" categories. The majority of fish recorded during this survey were spent, accounting for $71 \%$ of the biomass and $62 \%$ of the numbers. This indicates that spawning may have taken place before the survey. Anecdotal information from fishermen suggests peak spawning time now occurs between January and February.

The age distribution of the abundance estimate from the acoustic survey and from the commercial fishery in 2003 is presented in Figure 6.3.2.3. Dominant ages in the acoustic survey were 2-ringers (2001 year class) and 3-ringer fish ( 2000 year class) making up $32 \%$ and $36 \%$ of numbers respectively. Fish of 4-rings and above accounted for $19 \%$ of numbers in the survey. The age distribution in the commercial fishery was different, with 2-ringers being slightly more numerous than 3-ringers. The total biomass estimate for the area surveyed was $10,300 \mathrm{t}$, with an SSB of $9,500 \mathrm{t}$. This is much lower than the estimates obtained in the mid- 1990's, though those surveys are not directly comparable, because they targeted the entire stock area during the feeding phase.

### 6.4 Mean weights-at-age

The mean weights ( kg ) at age in the catches in 2002 are based on Irish catches and are very similar to 2001 for ringers 1-6 (Table 6.4.1). These mean weights display quite a stable pattern over the time-series. Though there appears to be a slight increase in mean weights in the past three years (Figure 6.4.4.1).

The mean weights in the stock at spawning time have been calculated from Irish samples taken during the main spawning period that extends from October to February (Table 6.4.2). The values are higher for all the important age groups than in 2002.

There are currently no recruitment indices available for this stock. However an Irish ground fish survey conducted in the $4^{\text {th }}$ quarter since 1996 regularly catches herring. The data from this survey series will be investigated as a potential 1-ringer index and a presentation will be made to the HAWG in 2005.

### 6.6 Stock Assessment

There is no reliable tuning series for this stock, and tuned assessments have not been carried out for a number of years. Recently, the group has carried out separable VPA's, screening over a range of terminal F's. This approach allows for a study of the development of the stock, but prevents any conclusions being made in the most recent years.

### 6.6.1 Data exploration and preliminary assessments

A separable VPA was used to screen over three terminal fishing mortalities, $0.2,0.4$ and 0.6 . This was achieved in the Lowestoft VPA software (Darby and Flatman, 1994). Reference age for calculation of fishing mortality was 3-7 and terminal selection was fixed at 1, relative to age 4 (winter rings). Default downweighting was chosen. This assessment is still experimental, and no assessment has been accepted by ACFM in recent years.

### 6.6.2 Results of the assessment

Three assessments are presented, based on the three choices of terminal F. Without access to ancillary data, the group was unable to make an informed choice between them. The general development of the stock is presented in Figure 6.6.2.1. This figure is more informative for earlier years, but in most recent years it is less so.

Outputs from separable VPAs with terminal F's of $0.2,0.4$ and 0.6 are presented in Tables 6.6.2.1, 6.6.2.2 and 6.6.2.3 respectively. All scenarios suggest that F has decreased since 2001, and this is mirrored by a reduction in landings in recent years. Recruitment appears to have decreased slightly in the last year. SSB appears to have increased slightly, based on all scenarios, but in all cases it remains at a low level compared to the mid 1980's. Residual plots for these three runs are presented in Figure 6.6.2.2, 6.6.2.3 and 6.6.2.4.

In interpreting these data, it should be noted that herring is not a target fishery in this area at present. The catch-atage data may not be considered very informative. For instance, larger fish ( $>31 \mathrm{~cm}$ ) appear in the north Donegal area in the first quarter, but these are not always caught by the fishery, because the fleets are fishing mackerel instead. Indeed, the difference in the age compositions between the fishery and the acoustic survey may reflect the lack of coherence in the catch-at-age data.

### 6.7 Stock Forecasts and Catch Predictions

In the absence of an agreed assessment, it was not considered informative to carry out any predictions. However a prediction, produced for illustrative purposes, was produced by the HAWG in 2003. Since no final assessment was agreed on by the working group in 2004, the prediction carried out in 2003 is still considered relevant.

### 6.8 Medium-term Projections

No medium-term projections were carried out for this stock because of the absence of information. A management plan is currently being implemented to rebuild this stock.

### 6.9 Reference Points

As this assessment is still uncertain there was no revision of the precautionary reference points. The precautionary reference points for this stock were discussed in the 1999 Working Group Report (ICES 1999 ACFM:12). The present analysis, although it is uncertain, presents a similar picture of the stock as that shown in recent years. The SGPRP (ICES 2003/ACFM: 15) has reviewed the methodology for the calculation of biological reference points, and applying a segmented regression to the stock and recruit data from the 2002 HAWG assessment showed that the fit to the stock and recruit data for this stock was not significant. This may be due to the fact that recruitment does not show any clear dependence on the SSB.. The stock may be still below $\mathbf{B}_{\mathrm{pa}}(110,000 \mathrm{t})$ but the fishing mortality has been reduced, since 1998.

### 6.10 Quality of the Assessment

The assessment presented was based on the results from a separable VPA without a tuning index, therefore the estimates of SSB and F for recent years will be depending on the choice of terminal F. Although landings seem to have been low and stable in recent years the real F cannot be determined therefore the VPA was run for a range of F values and the current perception of the stock would be highly influenced by that choice. Further, there is no information on recent recruitment levels both because the selectivity of the fishery appears to be low for the juveniles and for the lack of a recruitment index.

The fishery is opportunistic and changes in fishing patterns are to be expected in respect to herring so the catch-atage data is likely to contain little information. A consistent time-series of fishery independent data would provide a tuning fleet which is the piece of information required to estimate the current state of the stock.

### 6.11 Management Considerations

The results of the non-tuned assessment suggest that the sharp decline in SSB may have stopped but the current level of SSB is uncertain. There is no evidence that large year classes have recruited to the stock in recent years and F appears to have been reduced due to the reduction in catch. The management of the Irish fishery (which takes most of the catch) has improved over the past years and catches have been considerably reduced since 1999. The reduced catches over this period have resulted in a reduction in fishing mortality, although it is not possible to be precise about the current levels.

Despite the uncertainty about this stock, it is clear that it is at a much lower level in recent years, than before. The fisheries exploiting this stock should not be allowed to expand. At present the main fleet exploiting the stock is mainly targeting mackerel and horse mackerel. Measures should be taken to ensure that this stock is afforded protection if the current situation were to change.

SSB may be increasing slightly, but it is still well below historical levels. Though the peak in SSB in the 1980's may have been an isolated event the HAWG suggests that this stock should be exploited with caution. F appears to have been substantially reduced since 1998. Though little information on recruitment is available, it is unlikely that it is above average.

The opportunistic nature of the fishery means that there is a lack of information in the data and this impedes the provision of more accurate perceptions of stock status. There are essentially two fleets exploiting this stock, the smaller polyvalent vessels tend to target the stock more than the larger boats. The HAWG notes that increased accuracy in the catch data over the past 3 years gives a greater confidence in the perception of stock development. It may be useful to collect biological data from each fleet separately, in order to refine the information from catch-at-age data. In order to obtain a proper assessment of this stock for the most recent years, reliable survey data are required. The current acoustic survey index dates from 1999. By the next working group, 7 years of data will be available and it should be possible to use this a tuning index. However the timing of the surveys means that they only cover part of the stock.

Anecdotal information and observations by scientists shows that industrial fisheries are in operation in the area just north of the boundary of VIaN and VIaS. The by-catch of herring in these fisheries should be evaluated.
Table 6.1.2.1 $\operatorname{VIa}(S) \&$ VIIb,c. Estimated Herring catches in tonnes, 1988-2003. These figures do not in all cases correspond to the official statistics and cannot be used for management purposes.

## $7 \quad$ Irish Sea Herring (Division VIIA (North))

### 7.1 The Fishery

### 7.1.1 Advice and management applicable to 2003 and 2004

In 1998 and 1999 the shrinkage option in ICA was applied due to the instability in the assessment. The model estimate of F was shrunk to the mean of the ten previous years. In 1999 , ACFM commented that F was still above $\mathbf{F}_{\mathrm{pa}}=0.36$, and should be reduced. In 2000 there was uncertainty in the size of the actual catches so a catch $(6,900 \mathrm{t})$ reflecting status quo F ( 0.26 ) was recommended. In 2001, there was again uncertainty concerning the actual catches so a catch ( $4,800 \mathrm{t}$ ) based on the mean of the last five years was recommended for 2002. In the 2002 assessment, there was a suggestion of uncertainty in the size of the catches and the assessment was based on the official catches with the proviso that the SSB estimates were uncertain due to the unreliability of the size of the catch. Once again, ACFM felt that the HAWG 2002 assessment was too different from previous perceptions of the stock and advised that the catch in 2003 should not be allowed to increase above the advised 2002 TAC ( $4,800 \mathrm{t}$ ).

ACFM did not accept the HAWG 2003 assessment due to inconsistency in the survey data, a lack of a recruitment index, and the possibility of more than one stock in the management area. The advice was a catch equal to that reported in 2003 (approximately 2,400 t). A TAC of $4,800 t$ was subsequently adopted for 2004 . This was partitioned as $3,550 \mathrm{t}$ to the UK and $1,250 \mathrm{t}$ to the Republic of Ireland.

### 7.1.2 The fishery in 2003

The catches reported from each country, for the period 1986 to 2003 are given in Table 7.1.1 and total catches from 1967 to 2003 in Figure 7.1.1 (catch-at-age in Figure 7.1.2). Reported landings in 2003 for the Irish Sea amounted to 2,399 t. In 2003, the UK did not take its entire quota and the Republic of Ireland reported no landings of herring from Division VIIa (N). The number of vessels targeting herring in the Irish Sea in 2003 was small, the majority from Northern Ireland with some representation from Scotland. According to the reported landings all of the significant catch was taken in the $3^{\text {rd }}$ and $4^{\text {th }}$ quarters. This year higher catches were slightly later in the year, in the fourth quarter. There was no Mourne gillnet fishery.

In 2003 the UK fishery opened in July. Closed areas for herring fishing in the Irish Sea along the east coast of Ireland and within 12 nautical miles of the west coast of Britain were maintained throughout the year. The traditional September gillnet fishery on the Mourne herring, which has a derogation to fish within the Irish closed box, did not take place again in 2003. The area to the east of the Isle of Man, encompassing the Douglas Bank spawning ground (described in ICES 2001, ACFM:10), was closed from 21 September to 15 November. Boats from the Republic of Ireland are not permitted to fish east of the Isle of Man.

### 7.2 Biological composition of the Catch

### 7.2.1 Catch in numbers

Catches in numbers-at-age are given in Table 7.2.1 for the years 1972 to 2003 and a graphical representation is given in Figure 7.1.2. The predominant year class in 2003 was the 2 - rings ( 2000 -year class), with the 1996 -year class also still being prevalent. The catch in numbers at length is given in Table 7.2 .2 for 1988 to 2003. In 2003 two modes were evident, reflecting the relatively poor representation of 5 -ring fish in the catch (see Table 7.2.2). The strong 1996-year class (6-ring) was also evident in the acoustic estimates (see Section 7.3.1).

### 7.2.2 Quality of catch and biological data

There was a suggestion that the landings data for herring in Division VIIa(N) were un-reliable between 1998 and 2001 (ICES 2002 ACFM:12). A re-examination of these data by the institute where most of the landings occur, resulted in the conclusion that the landings data for this time period are no more un-reliable than landings data in any adjacent management area. There are still no estimates of discarding or slippage of herring in the Irish Sea fisheries that target herring. Biological sampling of this fishery remains high (approximately 1 sample per 270 t landed) (Table 7.2.3), however, there is a suggestion that there may need to be some revisions for the 2003 data. All sampling was undertaken by Northern Ireland.

### 7.3.1 Acoustic surveys

The information on the time-series of acoustic surveys in the Irish Sea is given in Table 7.3.1. Note that the $1+$ biomass for 1998 has been revised from 21,200 to to 14,500 t to exclude 0-ring fish inadvertently included in the tables given in previous Working Documents and HAWG reports. Also note that the SSB data are different from those reported in previous Working Group Reports because they have been revised using the annually varying maturity ogive (see Table 7.4.3; estimated from the commercial catch data) used in the assessment by the Herring Assessment Working Group.

The acoustic survey in 2003 was carried out from 7 to 20 September (Figure 7.3.1), using a similar survey design of stratified, systematic transects used in previous years. Very few trawl catches of adult herring have been made off the Irish and English coasts over the period of the surveys, and a more intensive survey of these regions, at the expense of time spent around the Isle of Man, remains unwarranted at present. In general, there are few data on the age composition of the herring in the acoustic survey data. The survey followed the methods described in Armstrong et al., 2004 WD 1; see Annex 7).

Mixed herring targets were detected at a number of locations off the west and south coasts of the Isle of Man, including in layers close to the seabed in deep water off the NW of the IOM (Fig. 7.3.1a). Trawl samples contained a relatively high proportion of young fish of $18-25 \mathrm{~cm}$ (mainly 1-2 ring fish attaining 2-3 years of age in autumn 2003), confirming reports from fishermen operating in this area. The survey was suspended overnight on 11/12 September to investigate herring schools detected by commercial vessels close inshore at Laxey on the NE coast of the Isle of Man. The presence of herring in this area was confirmed acoustically and the fish were caught by trawl. Herring were not detected in the surrounding regions during this exploratory survey. When the survey proper recommenced later in the day, herring were detected about 8 miles south of Laxey but not in the area where they had been found on the exploratory survey. It was possible that the fish had moved southwards with the tide during the intervening period. Data from the exploratory transects were therefore not included in the biomass estimate. A patch of dense herring schools was also detected further offshore off the east coast of the Isle of Man. As in previous years, no herring schools were detected in the area immediately north of the Isle of Man (Dickey-Collas et al. 2001), despite an abundance of early-stage larvae in this area in November (see Armstrong et al. 2004 WD1). Spawning in this area must have commenced after the date of the acoustic survey.

Herring in areas of the Irish Sea away from the Isle of Man were predominantly 0-rings of mean length $11-14 \mathrm{~cm}$ fish with some 1-rings of mean length $18-20 \mathrm{~cm}$. Sprats and 0 -ring herring were abundant around the periphery of the Irish Sea (Fig. 7.3.1b).

The estimate of herring SSB of $24,390 t$ for 2003 was above the average for the time-series, although close to the average for the last four years. The approximate coefficient of variation of 0.24 was the second lowest in the series of surveys. The biomass estimate for $1+$ rings $(49,500 \mathrm{t})$ was the largest in the series, whilst the CV of 0.22 for the stratified mean estimate was the second lowest in the series. The estimated age composition of the herring population, excluding 0 -ring fish, is given in Table 7.3.2.

### 7.3.2 Larvae surveys

A larvae survey was undertaken by Northern Ireland (3-7 and 10-14 November 2003) but there was no survey by the Port Erin Marine Laboratory. The survey followed the methods and designs of previous surveys in the time-series (see Annex 7). The production estimate for 2003 in the NE Irish Sea was lower than the previous year for the November survey (Table 7.3.3). Once again, there were very few Mourne larvae caught in the Northern Irish survey.

### 7.3.3 Groundfish surveys of Area VIIa(N)

Groundfish surveys (see Annex 7), carried out by Northern Ireland since 1991 in the Irish Sea, were used by the 1996 to 1999 Herring Assessment Working Groups to obtain indices for 0 - and 1-ring herring in the Irish Sea (Table 7.3.4) (Armstrong et al. 2004 WD1). The ground fish survey index, based on these data and used by the 1997 to 1999 Working Groups was a variance weighted mean abundance of each year class across the surveys. In 2000 the working group analysed these data and decided that the arithmetic mean abundance data (within strata) of 0-ring and 1-ring fish were more suitable as a prospective index of recruitment strength (Table 7.6.1). The standard errors are generally high over the series (coefficients of variation $\pm 50 \%$ ). There is no consistent pattern between indices from the western and eastern Irish Sea and further investigations are required into the dynamics of juvenile abundance and distribution in the seas around Ireland. Both series are influenced by the variable number of Celtic Sea fish in the Irish Sea (see Brophy \& Danilowicz 2002).

### 7.4 Mean length, weight, maturity and natural mortality-at-age

Mean lengths-at-age were calculated using the Northern Ireland data and are given for the years 1985 to 2003 in Table 7.4.1. In general, mean lengths have been relatively stable over the last few years.

Mean weights-at-age in the catch are given in Table 7.4.2. Mean weights-at-age of all ages were still generally low compared with previous years. There has been a change in mean weight over the time period 1961 to the present (ICES 2003 ACFM:17). Mean weights-at-age increased between the early 1960s and the late 1970s whereupon there was been a steady decline to the early 1990s. In the assessment, mean weights-at-age for the period 1972 to 1984 are taken as unchanging. In extending the data series back from 1971 to 1961 mean weights-at-age in the catch were taken from samples recorded by the Port Erin Marine Laboratory (see ICES 2003 ACFM:17).

Mean weights-at-age in the third-quarter catches (for the whole time-series 1961 to present) have been used as estimates of stock weights at spawning time. There is some uncertainty in the mean weights-at-age presented to the WG, as such the WG have used the average mean weights-at-age for the last five years. These will be revised next year.

Maturity-at-age (in the catches) for each year (1961 to 2003) are given in Table 7.4.3. Due to inconsistencies in the 2003 maturity data, a mean maturity ogive for the last nine years was used for 2003. The rationale for the 9 years was that there appeared to be a shift in the maturity ogive around 1993.

As in previous years, natural mortality per year was assumed to be 1.0 on 1-rings, 0.3 on 2-rings, 0.2 on 3-rings and 0.1 on all older age classes. These are based on the natural mortality rates determined for herring in the North Sea.

### 7.5 Recruitment

There are currently no recruitment indices for this stock.

### 7.6 Stock Assessment

### 7.6.1 Data exploration and preliminary modelling

In the previous year's the assessment, three fishery independent survey indices were used: Douglas Bank larvae abundance, Northern Irish larvae production and the age dis-aggregated abundance from the acoustic survey. There has now been some doubt raised as to the value of the age dis-aggregated acoustic data. This is due to the variability in the estimates of numbers at age, primarily caused by the low number of samples taken in the acoustic survey (Armstrong \& Roel 2004 WD). The low sampling rate introduces a large amount of noise in to the age matrix in the acoustic survey data. In an effort to avoid the age structure problems associated with the acoustic data Armstrong and Roel (2004 WD) suggested the use of the $1+$ biomass index as an alternative. The use of a $2+$ biomass index or an SSB index from the acoustic survey would also be dependent on a reliable age matrix in the acoustic data. Roel and De Oliveira (2004 WD) also presented a two-stage biomass model as an alternative approach to using the standard ICA. This is also explored below.

This year, the preliminary modelling used catch-at-age data derived from the official landings, extended back to 1961. New data were added to the Northern Irish larvae series (NINEL), the Northern Irish acoustic survey (AC_1+, $\mathrm{AC}-\mathrm{VIIa}(\mathrm{N})$, and ACAGE), October and March groundfish surveys for the east, west and combined areas (Table 7.6.1). No new data were added to the Douglas Bank larvae series (DBL). The Division VIIa(N) acoustic survey estimates are not considered as absolute because of discrepancies between acoustic estimates and tuned SSB estimates seen in other herring stocks.

The survey series available for inclusion in an assessment using the ICA package are documented in Appendix 7.
Due to the problems associated with mixing of Irish Sea and Celtic Sea juveniles none of the groundfish surveys were considered as suitable. However, due to the potential problem with the age structure of the acoustic data an acoustic $1+$ biomass index was also considered. Therefore, only the three indices used last year plus the $1+$ biomass index were considered suitable for this year (NINEL, DBL, ACAGE and AC_1+).

Initial fits within integrated catch-at-age analysis (ICA), were found in 2004 with all three indices. The following input values were used:

- Separable constraint over the last 6-years (weighting $=1.0$ for each year)
- Reference age $=4$
- Constant selection pattern model
- Selectivity on oldest age $=1.0$
- First age for calculation of mean $F=2$
- Last age for calculation of mean $F=6$
- Weighting on 1-rings $=0.1 ;$ all other age classes $=1.0$
- Weighting for all years $=1.0$
- All indices treated as linear
- No S/R relationship fitted
- Lowest and highest feasible $\mathrm{F}=0.05$ and 2.0
- All survey weights fitted by hand i.e., 1.0 with the 1 -rings in the acoustic survey weighted to 0.1 .
- Correlated errors assumed i.e., $=1.0$
- No shrinkage applied

The Northern Irish larvae index (NINEL) indicated the lowest reference F ( 0.225 ) compared to the acoustic index (ACAGE 0.328), however, both have relative large confidence intervals (Figure 7.6.1). The Douglas Bank larvae (DBL) gave the highest reference $\mathrm{F}(0.422)$ and the lowest precision with very wide confidence intervals probably partially reflecting the lack of new data for the last four years. As in last year the precision in F was greater for NINEL and ACAGE than DBL, however, the precision appeared less than last year. A run was undertaken using all the indices used last year (SPALY) and this indicated a reference $\mathrm{F}(0.288)$ intermediate between the various indices but with relatively poor precision compared to 2003 analyses.

Using the Acoustic age $1+$ biomass as an SSB index (AC_1+) gave a lower and relatively precise reference F (0.164) (Figure 7.6.1) suggesting that the aggregate biomass indices from acoustics do not seem to be totally out of line with what ICA generates.

The larvae production estimates of SSB (NINEL) was combined with the Acoustic 1+ biomass to provide another perception of SSB. The result was a slightly increased Reference F ( 0.202 ) and similar level of precision compared to SPALY.

The historical and recent trends in log catch ratios and catch per estimated acoustic biomass ( $1+$ ) were investigated along cohorts to give some indication of trends in Z and consistency between the different sources of information.

An investigation of the log abundance ratios estimated in the acoustic survey indicate a relatively noisy pattern across year classes with a few exceptions (Figure 7.6.2). In the period 2001 to 2002 there appeared a year effect in the older year classes that was not apparent in the younger years classes. This is not apparent in the catch data. The large year effect in 2000 in the catch data was caused by a very low reported catch in 2000.

Examination of the rate of exploitation in terms of the catch to acoustic estimated $1+$ biomass ratios, suggest an increase from 1995 to 1998 and a relatively lower exploitation rate over the period 1999 to 2003 (Figure 7.6.3). This suggests that the fishing mortality has probably been relatively stable over this time period.

The historic average depletion rates of year classes over age show the very high depletion rate (high slopes) over the 1970 to 74 year classes and to a certain extent the 1975 to 79 year classes (Figure 7.6.4). This corresponds to the period of very high catches in the Irish Sea. In general, the 1980 year classes onward have shown a consistent lower depletion rate, especially in the last few year classes (1995 to 98), suggesting a relatively stable Z over this time period. These data suggest that in the recent past there has not been a substantial increase in total mortality and, assuming a constant natural mortality $(\mathrm{M})$, that there has not been a substantial increase in fishing mortality ( F ).

To examine how the $1+$ biomass index performed as a $1+$ biomass index ICA was run with the maturity ogive set to 1.00 for all ages and AC_1+ used as the index. The resultant trajectory of SSB for the runs using AC_1+ as a biomass index and as an SSB index are given in Figure 7.6.5. Overall, the pattern is similar, however, there are small differences in the most recent years that are not likely to be significant. However, the $1+$ index includes 1-and 2-ring fish which are from two different stocks (Celtic Sea and Irish Sea) therefore it should be treated with caution. Further, the influence of year to year variations in numbers and proportions of these young fish in the Irish Sea is still unknown (Brophy and Danilowicz 2002).

To investigate the uncertainty in the estimated F and SSB from ICA a series of estimates of uncertainty from the ICA bootstrapped mean F and SSB for the three main indices was obtained (Figures 7.6.6; 7.6.8-9). The NINEL index has the largest range in both F and SSB. As is to be expected with relatively noisy data the Acoustics age-structured index (ACAGE) has a greater variability in F than AC_1+ but the reverse is true in the estimates of SSB. The noisy nature of the indices is transferred to a large uncertainty in F in the SPALY run (Figure 7.6.7-9), SSB in the AC_1+ run and in both for the AC_1+\& NINEL run. However, an examination of the box plots for the various individual choices and combined suggest similar variability in the case of F although the acoustic 1+index provides more precise estimates compared with the other options. The acoustics age-structured index performs best when estimating SSB.

Explorations were made on the retrospective use of the $1+$ biomass index (see also Armstrong and Roel 2004 WD) and on the SPALY run (DBL, NINEL and ACAGE). There was a relatively constant retrospective performance in estimating SSB by the $1+$ biomass index (Figure 6.7.10). The pattern from the SPALY run showed similar features although it was performed only for the last four years. The largest deviation from all other values corresponds to an extremely high estimate of recruitment in 2002 (Figure 6.7.11). As information on recruitment is poor in both the catch at age and the survey, that is not surprising.

## Two-stage biomass model

An Assessment of Irish Sea VIIa herring using a Two-Stage Biomass model was presented by Roel and De Oliveira (2004 WD) based on an approach developed by Roel and Butterworth (2000). The model was fitted to the biomass of 1-ringers and 2+ ringers of the Northern Ireland acoustic survey for the period 1994 - 2003. The dynamics takes into account only two stages in the population: the recruits (1-ringer) and the fully recruited fish (2-ringer and older). Maximum likelihood estimation is used, assuming survey indices are log-normally distributed about their expected values. Standard errors of the log-distributions are approximated by the sampling CVs. The results are sensitive to the choice of the composite parameter $g$ (see equation 1) which is fixed externally. A comparison is made between the total biomass estimates from the survey, the two-stage biomass model and ICA (using the acoustic $1+$ index). Both the acoustics index and the two-stage model suggest an increasing trend in the stock biomass starting in 1998. Given the number of "independent" data versus number of estimable parameters the two-stage biomass model is likely to be over-
parameterised. A more constrained model (e.g. not allowing the recruitments to vary so freely) could be attempted to address that concern.

Population Dynamics: The biomass dynamics are represented by the following:

$$
\begin{equation*}
B_{2+, y+1}=\left[\left(B_{2+, y}+B_{1, y}\right) e^{-3 g / 4}-C_{y}\right] e^{-g / 4} \tag{1}
\end{equation*}
$$

where:
$B_{1, y}$ is the biomass of recruitment (tons) at the start of year $y$;
$B_{2+, y}$ is the biomass of 2+ aged fish (tons) at the start of year $y$;
$C_{y}$ is the biomass of fish caught (tons) during year $y$, assumed to be taken in a pulse fishery $3 / 4$ of the way into year $y$; and
$g$ is a composite parameter, treated as an annual rate, which accounts for natural mortality and growth.
Fitting criterion: Maximum likelihood estimation is used, assuming survey indices are log-normally distributed about their expected values. Standard errors of the log-distributions are approximated by the sampling CVs of the untransformed distributions. The negative log-likelihood function to be minimised is as follows:

$$
\begin{equation*}
-\ln L=\frac{1}{2} \sum_{a=1,2+} \sum_{y=1994}^{2003}\left\{\frac{\left[\ln I_{a, y}-\ln \left(q_{a} B_{a, y} e^{-3 g / 4}\right)\right]^{2}}{\sigma_{y}^{2}}+\ln \left(2 \pi \sigma_{y}^{2}\right)\right\} \tag{2}
\end{equation*}
$$

where $q_{1}$ and $q_{2+}$ are the catchabilities associated with the survey indices $I_{1, y}$ and $I_{2+y}$ respectively, and $\sigma_{y}^{2}$ represents the survey sampling CV (the same value is assumed to apply to both indices), calculated from the 15 -minute acoustic interval estimates within strata.
The estimable parameters are $g, B_{2+, 1994}, B_{1,1994}, \ldots, B_{1,2003}, q_{1}$ and $q_{2+}$. However, only $B_{2+, 1994}, B_{1,1994}, \ldots, B_{1,2003}$, are included as search parameters in the minimisation routine, because $g$ is treated as an input parameter (and therefore fixed externally), while closed form solutions exit for $q_{1}$ and $q_{2+}$ as follows:

$$
\begin{equation*}
q_{a}=\exp \left\{\frac{1}{10} \sum_{y=1994}^{2003}\left[\ln I_{a, y}-\ln \left(B_{a, y} e^{-3 g / 4}\right)\right]\right\} \quad, \text { for } a=1 \text { or } 2+\cdot \tag{3}
\end{equation*}
$$

In order to investigate appropriate values for g , an estimate of $g_{a}$ was obtained based on estimates of biomass at age ( $B_{y, a}$ ) from ICA (acoustic $1+$ biomass as a tuning index) and the landings ( $C_{y, a}$ ) for the period 1994-2003 as follows:

$$
\begin{equation*}
g_{a}=\ln \left[\frac{B_{y, a}-C_{y, a}}{B_{y+1, a}}\right] \tag{4}
\end{equation*}
$$

The distribution of $g_{a}$ suggests that a value around 0.2 could be appropriate. Sensitivity to that assumption was tested for values of $g$ equal to 0.4 and 0.6 .

Results: A comparison between the biomass estimates from ICA (procedure as in last year (SPALY) and using acoustics 1 plus as SSB index), the biomass estimate from the acoustic survey and the biomass estimate from the twostage biomass model are shown in Figure 7.6 .12 showing a good fit from the model to the survey index.

The normalised residuals from the model fit for $g=0.2,0.4$ and 0.6 are shown in Figure 7.6.13. Stronger patterns are shown for $\mathrm{g}=0.2$.

## Conclusion to explorations

Due to uncertainty in the various tuning indices and potential assessments examined in relation to the 2003 assessment it was decided to present the SPALY run, updated for the current year to provide an indication of the historical development of the stock. The results from the two-stage biomass models were presented as exploratory.

### 7.6.2 Stock Assessment

The work shown is an updated exploratory assessment and no analytical assessment is presented this year. The results of a baseline model fit (with ACAGE, NINEL and DBL) are shown in Figures 7.6.14-7.6.18, for illustrative purposes only. The run $\log$ is given in Table 7.6.2. Some of the standard plots for the indices are not shown due to problems encountered with using IcaView in Windows 2000, the residuals and fitted values are given in Table 7.6.3. The SSQ for the index shows a minimum at a relatively low level of fishing mortality (Figure 7.6.3). The estimate for $\mathrm{F}_{(2-6)}$ for 2003 using the official landing data was 0.25 (Table 7.6 .3 ) with a corresponding SSB estimate of approximately 8,400 t. The assessment shows estimated fishing mortality and SSB in the last few years to be similar to previous estimates. The standard fish stock summary plots are not given as these may be misleading, similarly there is no plot of $\mathbf{F}_{\text {low }}, \mathbf{F}_{\text {med }}$ and $\mathbf{F}_{\text {high }}$.

### 7.7 Stock and Catch Projection

No Short-term predictions were carried out due to the uncertainty of the current F, SSB and subsequently numbers-atage. The explorations of the data suggest that current total $(\mathrm{Z})$ and fishing $(\mathrm{F})$ mortalities are either similar or lower than
in the recent past and that the SSB has been stable. Similarly there does not appear to have been any major shift in the selection pattern within this fishery in recent years.

In 2003, the UK did not take its full quota and the Republic of Ireland did not participate in the fishery. There is still no evidence that the fleets will take their quota ( $4,800 \mathrm{t}$ ) in 2004, therefore there is every possibility that fishing mortality in 2004 will not rise dramatically. These low levels of fishing should allow the stock to maintain a status quo SSB , if not allow the SSB to rise.

### 7.8 Medium-term predictions of stock size

The Working Group decided that there was no basis for undertaking medium-term projections of stock size until the assessment is stable and there is agreement that advice can be given based on the assessment. The current state of herring recruitment to $\mathrm{VIIa}(\mathrm{N})$ is unclear, considering the imprecision in the assessments and the variable mixing of Celtic Sea and Irish Sea juveniles. Also the historical assessments of recruitment have incorporated both Manx and Mourne components and the contribution of the Mourne component is now thought to be negligible.

### 7.9 Reference points

Until there is confidence in the assessment the Working Group decided not to revisit the estimation of $\mathbf{B}_{\mathrm{pa}}(9,500 \mathrm{t})$ and $\mathbf{B}_{\text {lim }}(6,000 \mathrm{t})$. There were no new points to add to the discussions and deliberations presented in 2000 (ICES 2000/ACFM:12).

### 7.10 Quality of the Assessment

The current time-series of survey data are prone to providing variable perceptions of stock development due to variability in catchabilities of the indices. This WG explored the data using a wide range of techniques, some of them fairly crude and others, innovative. The exploration of the data showed poor precision in the estimation of SSB and F, but a broad suggestion that mean $\mathrm{F}_{2-6}$ was below 0.4 (Figures 7.6.7-9) in 2003. The analysis suggests that the selection pattern has stabilised in the last 6 years.

The tuning data used in the assessment are noisy and that results in imprecision and, at times instability. The imprecise estimates of SSB show either no trend with time in recent years or are slightly divergent, depending on the indices or assessment methods used. There have probably been changes in this stock since the early 1990s, with reductions in weights-at-age and changes in spawning behaviour. Spawning sites have varied with notable spawning to the north of the Isle of Man and the reduction in the Mourne component and may partially explain the changes referred to above. It is likely, however, that the SSB has stabilised over recent years.

### 7.11 Spawning and Juvenile Fishing Area Closures

The arrangement of closed areas in Division VIIa(N) prior to 1999 are discussed in detail in ICES (1996/ACFM:10) with a change to the closed area to the east of the Isle of Man being altered in 1999 (see ICES 2001/ACFM:10). The closed areas consist of: all year juvenile closures along part of the east coast of Ireland, and the west coast of Scotland, England and Wales; spawning closures along the east coast of the Isle of Man from 21st September- 15 th November, and along the east coast of Ireland all year round. The Working Group recommends that any alterations to the present closures are considered carefully, in the context of this report, to ensure protection for all components of this stock.

### 7.12 Management considerations

The tuning data sets have varied considerably between years, for example including or excluding groundfish survey data, thus providing considerable between year variation in the perception of the stock. Currently there are no recruitment indices to provide a forecast of recruitment plus the juveniles in the area are a mixture of two adjacent stocks (Celtic Sea and VIIa(N)). However, the catches have been low in recent years and there are no indications of problems in the catch-at-age for this stock. Analytical retrospectives suggest that the assessments examined are relatively stable. Further, a broad range of year classes is present in the stock. Therefore, the maintenance of recommended catch levels of approximately $5,000 \mathrm{t}$, in the short-term, should not be detrimental to the stock.

Table 7.1.1 Irish Sea herring Division VIIa(N). Official catch in tonnes by country, 1986-2003. The total catch does not in all cases correspond to the official statistics and cannot be used for management purposes.

| Country | 1986 | 1987 | 1988 | 1989 | 1990 | 1991 | 1992 | 1993 | 1994 |

1. Mean abundance of juveniles (within strata) per 3 nm trawl, surveyed when aged 0 in September and 1 in the following September and used as indices for the following years, for either the eastern Irish Sea or total northern Irish Sea.
2. Mean abundance of juveniles (within strata) per 3nm trawl, aged 1 in March from the eastern Irish Sea.
3. Numbers of larvae at $6 \mathrm{~mm} \times 10^{11}$, a size weighted index.
4. Biomass of SSB, tonnes from acoustic surveys of the northern Irish Sea.
5. Biomass of total stock in $\mathrm{VIIa}(\mathrm{N})$ aged 1-ring and greater, tonnes from acoustic surveys.
na- not available. GFS-Ground fish survey. DBL- Douglas Bank Larvae. NINEL- Northeast Larvae. AC- Acoustic.

## STOCK SUMMARY

No of years for separable analysis : 6
Age range in the analysis : 1 . . . 8
Year range in the analysis : 1961 . . . 2003
Number of indices of SSB : 2
Number of age-structured indices : 1
Parameters to estimate : 33
Number of observations : 144
Conventional single selection vector model to be fitted.

Table 7.6.3 continued Herring Irish Sea VIIa(N). Age = rings

## PARAMETER ESTIMATES

SSB Index catchabilities DBL
Linear model fitted. Slopes at age :
$2412 \mathrm{Q} .4545 \mathrm{E}-01 \quad 12.4016 \mathrm{E}-01.6658 \mathrm{E}-01.4545 \mathrm{E}-01.5883 \mathrm{E}-01 \quad .5214 \mathrm{E}-01$
NINEL
Linear model fitted. Slopes at age :
252 Q .2746E-02 $15.2372 \mathrm{E}-02.4311 \mathrm{E}-02.2746 \mathrm{E}-02.3724 \mathrm{E}-02$. $3235 \mathrm{E}-02$

Weighted Statistics

Figure 7.1.1
Irish Sea Herring VIIa(N). Landings of herring from VIIa(N) from 1961 to 2003.

Figure 7.1.2 Irish Sea Herring VIIa(N). Landings (catch-at-age) of herring from VIIa(N) from 1961 to 2003.

Figure 7.3.1 Irish Sea Herring VIIa(N). DARD acoustic survey. Density distribution of (A) herring schools (mainly 1 -ring and older) and (B) sprats and 0 -group herring. Size of elipses is proportional to square root of the $\mathrm{S}_{\mathrm{A}}$ value for each 15-minute interval (same scale for figures A and B). Crosses indicate starting positions for 15-minute EDSUs. Acoustic survey strata are indicated.

Figure 7.6.1 Irish Sea Herring VIIa(N). Results in terms of reference F (age 4), of the preliminary modelling with ICA of survey indices described in Table 7.6.1. Error bars show the upper and lower $95 \%$ confidence limits.

Figure 7.6.2 Irish Sea herring VIIa(N). Log anundance/catch ratios for the period 1994 to 2002/3 by year for a. the acoustic survey (ACAGE and b. the catch at age.

Figure 7.6.3 Irish Sea Herring VIIa(N). Ratio of catch versus acoustic estimate of $1+$ biomass for the years 1995 to 2003.

Figure 7.6.4 Irish Sea Herring VIIa(N). Change in average log abundance of year classes (1961-1998) per age class (rings) for 5 year periods.

Figure 7.6.5 Irish Sea Herring VIIa(N). Variation in perception of SSB using the acoustic estimate of 1+ biomass either as an SSB or a total biomass index in ICA.

Figure 7.6.6 Irish Sea Herring VIIa(N). Estimates of uncertainty from the ICA bootstrapped mean F and SSB for the three main indices for the Irish Sea herring: Larvae production (NINEL), Acoustic numbers at age (ACAGE) and acoustic $1+$ biomass index (AC_1+). 50 bootstrapped values shown on the combined graph and 100 for each individual index. Estimated value for 2003 for each index is shown as the large symbol in the combined graph.

Figure 7.6.7 Irish Sea Herring VIIa(N). Estimates of uncertainty from the ICA bootstrapped mean F and SSB for the three options of single or combined indices in ICA for the Irish Sea herring: SPALY (DBL, NINEL \& ACAGE), acoustic 1+ biomass index (AC_1+) and Acoustic 1+ biomass plus NINEL. 50 bootstrapped values shown on the combined graph and 100 for each individual index. . Estimated value for 2003 for each run is shown as the large symbol in the combined graph.

Figure 7.6.8 Irish Sea Herring VIIa(N). Comparison of 2003 Reference F from ICA bootstrap realisations corresponding to the various tuning fleets or SSB (x-axis) explored: Acoustic age-structured (ACAGE), acoustic 1+ and larvae index (AC_1+\& NINEL), Acoustic 1+ (AC_1+), larvae index only (NINEL), same procedure as last year (SPALY) and all the bootstrap estimates combined. The box corresponds to the quartiles, the median is indicated with a dot and the caps indicate the nearest value not beyond a standard span from the quartiles (standard span is $1.5^{*}$ (Inter-Quartile range).

### 8.1 The Fishery

### 8.1.1 ACFM advice applicable for 2003 and 2004

ACFM advised that a catch of $257,000 \mathrm{t}$ in 2003 would allow the SSB to remain near or above the long-term average. This was based on the historic relationship between survey and catch. From 2002 to 2004 The TAC set by management for Subarea IV (EU zone) and Division IIa (EU zone) has been 257,000 t.

### 8.1.2 Total landings in 2003

Landing statistics for sprat for the North Sea by area and country are presented in Table 8.1.1 for 1987-2003. As in previous years, sprats from the fjords of western Norway are not included in the landings for the North Sea. Landings from the fjords are presented separately (Table 8.1.2) due to their uncertain stock identity. Table 8.1.3 shows the landings for 1994-2003 by year, quarter, and area in the North Sea.

The landings in 2003 were $176,000 \mathrm{t}$ and higher compared to the landings in 2002, which were $144,000 \mathrm{t}$. This increase was partly because the Danish fishery was not closed in late February and March, which it was in 2002. There was no Norwegian fishery in 2003. Neither Denmark nor UK (England and Wales) took their quota in 2003. The Danish fishery was responsible for all catches taken in the second and third quarter. Anecdotal information states that in November and December the sprat stock was more widely spread, and by-catch of herring was a limiting factor, therefore the small-meshed fishing fleet moved towards Norway pout instead.

No sprat was reported as by-catch in the landings from the Norwegian or the Swedish small-meshed fishery targeted at sandeel and Norway pout.

The quarterly and annual distributions of catches by rectangle for Subarea IV are shown in Figures 8.1.1-8.1.2.

### 8.2 Biological Composition of the Catch

### 8.2.1 By-catches in the North Sea sprat fishery

As requested by ACFM, data on the species composition of the by-catch is given in Table 8.2.1. Only data on by-catch from the Danish fishery were available to the Working Group. In general, more than $80 \%$ of the catches consist of sprat. The amount of herring caught as by-catch in the sprat fishery in 2003 is less than $6 \%$ of the total catch which is the lowest since 1999.

### 8.2.2 Catches in number

The estimated quarterly catch-at-age in numbers for the years 1995 to 2003 is presented in Table 8.2.2. Denmark provided age composition data of commercial landings in 2003 for all quarters except the $2^{\text {nd }}$ quarter. The age composition data from the $1^{\text {st }}$ quarter was used to raise the catches from the second quarter. Danish samples were used to raise the catches from England and Wales.

1-ringer sprat dominates the catches over all the years although the relative importance does vary with year. 0ringer sprat catches in 2003 were only slightly higher compared to 2002, being right on the average for the whole time period. The majority of catches is taken during the fourth quarter.

### 8.2.3 Quality of catch and biological data

The sampling intensity for biological samples, i.e., age and weight-at-age, is given in Table 8.2.4. The sampling level in 2003 is lower than in previous years. In Denmark the provisions in the EU regulation 1639/2001 have been implemented. This provision requires 1 sample per 2000 tonnes landed. This sampling level is lower than the guidelines ( 1 sample per 1000 tonnes) previously used by the HAWG, but as the fishery was carried out in a limited area, the recommended sampling level can be regarded as adequate.

The Danish monitoring schemes for management purposes for species composition in the Danish small-meshed fisheries has worked well in 2003. A total of 1201 samples were collected from landings taken in the North Sea by Danish vessels. The sampling figure for 2002 was 1054 samples. The total landings from the Danish small mesh fishery in 2003 were $506,000 \mathrm{t}$ (all species) compared to $885,000 \mathrm{t}$ in 2002. This reduction is mainly due to changes in the sandeel
fishery. The recommended sampling levels for species composition were achieved. The species composition in the Danish sprat fishery is shown in Table 8.2.1.

### 8.3 Fishery-independent information

The acoustic surveys for the North Sea Herring in June-July have estimated sprat abundance since 1996. In June-July 1998, sprat was mainly detected west of $1^{\circ} \mathrm{W}$ (R/V Tridens) (Simmonds et al, 1999). The acoustic estimates of sprat biomass in 1996-1998 were in the range of $40,000 \mathrm{t}$ to $210,000 \mathrm{t}$. In 1999 the acoustic estimate of sprat was very low. The low value was not thought to be representative mainly due to inappropriate coverage of the south-eastern area (ICES CM 2000/D:07), the area expected to have the highest abundance of sprat in the North Sea. In 2000 the survey was extended by $30 \mathrm{n} . \mathrm{mi}$ to the south and covered for the first time the south-eastern area considered to have the highest abundance of sprat in the North Sea. By doing so, the estimate of sprat increased significantly. The distribution pattern in 2003 demonstrates, however, that the southern distribution border was still not reached by the survey though it was expanded even further south in 2003. The total sprat biomass estimated in 2003 was $270,000 \mathrm{t}, 29,000 \mathrm{t}$ higher than in 2002 (ICES/2003:G:05).

### 8.4 Mean Weight-at-age and Maturity-at-age

Mean weights (g) at age in the catches during 2003 are presented by quarter in Table 8.2.3. The table includes mean weights-at-age for 1995-2003 for comparison.

During the Working Group in 2002, data on maturity and age were compiled from the Danish commercial catches during quarters 1, 3 and 4 in 2001. Data on maturity were provided from the German Acoustic surveys in June-July during 1996-2001.No other countries contributed with data on maturity. No reliable data on sprat maturity has been available since 2001 and thus the time-series was not updated during the Working Group 2004.

### 8.5 Recruitment

The IBTS (February) sprat indices (no. per hour) in IVb (sprat standard area) are used as an index of abundance. The historical data were revised in 1995 (ICES 1995/Assess:13) and 1999 (ICES 1999/ACFM:12). The IBTS Working Group redefined the sprat index to be calculated as an area weighted mean over means by rectangles for the entire North Sea sprat stock. Based on this, the IBTS WG asked ICES Secretariat to carry out new calculations in 2001 (ICES 2000/D:07), which are the ones used in the present report. The old and the revised IBTS index is available in the Working Group report from 2003 for comparison (ICES 2003/ACFM:17). The fishing method (gear) in the IBTS-survey was standardised in 1983 and the data series from 1984, are comparable. The IBTS-indices for 1984-2004 are shown in Table 8.5 .1 for age groups $1-4,5+$ and total. The index of 1 -group decreased slightly compared to the index from 2003, but is still above the mean of the time-series. The abundance of the 1998 year class was not detected as higher than average and is as $5+$-group below the average. The total-abundance index shows a minor increase compared to 2003, and is well above the average for the whole time-series. The old IBTS-indices are available in ICES 2001/ACFM:12.

The IBTS data by rectangle are given in Figure 8.3.1a-c for age groups 1, 2 and 3+. Age 1-group was again found to be concentrated in the south-eastern areas of Division IVb and Division IVc. The mean lengths (mm) of age group 1 by rectangle are presented in Figure 8.3.2.

### 8.6 State of the Stock

### 8.6.1 Data Exploration and Preliminary Modelling

Sprat is a relatively short-living species, the catches consisting mostly of 1 and 2 year-olds. In addition, there are difficulties in age reading resulting in unreliable estimates of numbers-at-age both from the surveys and the commercial catch. Given those limitations a data exploration using Catch-Survey Analysis (CSA), an assessment method designed for cases where full age-structured data are missing, was undertaken by the Working Group using an executable version made available by B. Mesnil (IFREMER). The method is based on the "modified DeLury" two-stage model (Conser 1995) and on an implementation tested on simulated data presented to the Methods Working Group in 2003 (Mesnil 2003). The model assumes that the population consists of two stages: the recruits (preferably a single year class which corresponds to the 1 year-old) and the fully recruited ages (the $2+$ group).

Model input data consisting of the time-series of catch numbers for each stage, mean weight for each stage in the stock at the start of the year and the 1st quarter IBTS index of abundance for the 1 year-old sprat (age $=$ number of winter rings) and older than 2 years-old are shown in Table 8.6.1 Weight-at-age, assumed constant for the whole period (1984-2003), was based on commercial data from the 1st quarter. Reservations regarding the ability of the IBTS 1-year-old index to fully reflect strong and weak cohorts for sprat were expressed in previous Working Group reports (see ICES 1998 ACFM:14). Those were linked to difficulties in age reading and/or a possible prolonged spawning and recruitment season. Another problem identified in some surveys was related to large catches in small areas which could have been very influential on the results. The Working Group in 2003 examined the biomass and the 1 year-old index trajectories and concluded that the observed fluctuations in overall biomass were likely to be related to fluctuations in
the 1 year-old index. This is to be expected in a population where the recruits account for a large proportion of the stock.

CSA requires values for the instantaneous rate of natural mortality $(\mathrm{M})$ and a parameter corresponding to the ratio of the survey catchability of the recruits to the fully recruited ages (s). Both parameters are fixed externally. The value of natural mortality is based on predation mortality estimates from a multispecies VPA (ICES $2002 \mathrm{CM} / \mathrm{D}: 04$ ). The results from the Study Group MSVPA for the North Sea were examined to provide information about plausible values for natural mortality. A value of 0.2 needs to be added to the estimate of predation mortality to account for other sources of mortality. Estimates of predation mortality at-age and $90 \%$ confidence intervals representing the variation over time from the MSVPA are shown in Fig. 8.6.1 for the period 1963 - 2000. The regression line in Fig. 8.6.2 indicates a decline in predation mortality in the period 1963-2000.

An observation-error only model which estimates catchability of the fully recruited stage by close-form solution $q_{n}=\exp \left(\operatorname{mean}\left(\log \left(n_{t} / N_{t}\right)\right)\right)$ was implemented. Numbers at the start of the year of fish $>2$-year-old in the first year of data and all the recruit numbers were estimated by least-squares minimisation. The recruits corresponding to the last year in the series were computed from the survey index and the recruitment catchability. The model is sensitive to the choice of the M and $s$ parameters. Given the constraints of the model which in its present form does not allow variations of M over time the model was run for $\mathrm{M}=0.7$ and 0.8 . In the absence of data that would support an alternative value $s$ was equated to 1.Model output is shown in Table 8.6.2. for $\mathrm{M}=0.7$.

Model fits for $\mathrm{M}=0.7$ to the IBTS indices are shown in Figure 8.6.3. Some conflict between the recruitment and the $2+$ indices is shown in 1989-1990 where the model was not able to account for the high recruitment estimated by IBTS. The model does not fit well the high IBTS 2+ index in 1998 given a low recruitment index in 1997; this could be an example of a late recruitment scenario where IBTS underestimated total recruitment. Estimated numbers of recruits and fully recruited and total biomass are shown in Fig. 8.6.4. Examination of the residuals suggests patterns in the fit to the recruits index, but less so in the case of the fully recruited. (Fig. 8.6.5). Confidence intervals for the parameters were estimated by means of non-parametric bootstrapping. Biomass point estimates (for $\mathrm{M}=0.7$ and 0.8 ) and $95 \%$ confidence intervals $(M=0.7)$ are shown in Figure 8.6.6. The biomass trajectory estimated by using $M=0.8$ falls between the confidence intervals for $\mathrm{M}=0.7$. Exploratory runs with M declining linearly between 0.83 and 0.68 were attempted, but the model failed to converge. Given that the dynamics depends largely on the 1 -year olds, it would be expected that the biomass trajectory would bend slightly downwards in recent years in relation to the run using $\mathrm{M}=0.8$. In other words, initially the biomass would follow a similar trajectory to the one corresponding to $\mathrm{M}=0.8$ but increasingly less so in recent years where it would approximate the trajectory corresponding to the run with $\mathrm{M}=0.7$.

Results from a retrospective analysis are shown on Figure 8.6 .7 suggesting a recent period of negative bias preceded by a long period where the biomass was revised upwards. The Working Group concluded from examination of Fig 8.6.5 that the retrospective bias was relatively small.

Although the Working Group was requested to do an update assessment the recent assessment should be regarded as still exploratory.

### 8.7 Projections of Catch and Stock

The SHOT- approach (Shepherd, 1991) was used in the past by the Working Group to estimate the landings in the assessment year. The Working Group considered that approach inappropriate for a short-lived species like sprat therefore the projection was based on the results from CSA. Biomass projections in 2004 and 2005, assuming median recruitment in 2005, for annual catches in 2004 and 2005 corresponding to the same exploitation rate as in 2003 are shown in Figure 8.7.1. The biomass trajectories suggest that the stock, depending on 2005 recruitment, would remain relatively stable under that level of exploitation.

A catch prediction for assessment year was provided in the past on the basis of a linear regression of catch versus IBTS estimated biomass. The results for 2003 are shown on Figure 8.7.2 and the corresponding catch prediction for 2004 is about $171,000 \mathrm{t}$.

### 8.8 Quality of the Assessment

Trends in the mean weights-at -age during the first quarter used to compute the biomass index from the IBTS have been reviewed. No trend was observed in the mean weights-at-age over time, therefore an average for the period 1995-2000 (sampling levels prior to 1995 were low) was used to compute stock biomass by means of Catch Survey Analysis. The model fits time-series of abundance for 2 stages in the stock: the recruits and the fully recruited to the fishery. The IBTS indices for the $1^{\text {st }}$ quarter were used as indicators. The Working Group is aware of problems associated with sprat in the IBTS (February) which may have hatched in autumn. However examination of the residuals from the model fit suggests that the problem results in additional noise in the data but the model still attains a reasonably good fit to the data. The results are sensitive to the value assumed for the catchability ratio $s$, the estimated biomass being scaled accordingly. Therefore, when examining the model output, emphasis should be placed on stock trends rather than on absolute values until an independent estimate of $s$ becomes available. Results from sensitivity tests to the assumed value of $M$ showed that the stock biomass would be scaled upwards when M increases. Further, available estimates of M suggest that it has declined in the period 1963-2000 from values just above 0.8 to about 0.7 . Given the dynamics of this short-living species recent estimates of biomass are likely to correspond to the trajectories derived from $\mathrm{M}=0.7$. Likewise, a value of s
$=1$ for IBTS is compatible with perceptions that catchability of recruits is no different from the one of the fully recruited. The Working Group agreed that an approach like CSA seemed a promising tool to assess sprat in the North Sea. Further, the method, although not specifically designed for short-lived species, does show potential for assessment in that context and therefore it is recommended that the Working Group of Methods again considers assessment methods for short-lived species in the light of recent developments.

### 8.9 Management Considerations

Prior to 1993, the sprat was caught with a relative high percentage of herring by-catch. In 1993, 1994 and 1995 the sprat fishery could be conducted with rather low herring by-catch percentages. In some periods in 1997 and 1998 it was stopped with the aim of protecting the juvenile herring and due to high by-catch of herring.

The sprat stock shows signs of being in good condition as the biomass appears to increase and there is indication from the IBTS (February)-2004-survey of a good 2003-year class recruiting to the 2004 fishery. In 1998-2000 the bycatch of herring was not a limiting factor in the sprat fishery and the main controlling factor was the TAC limits. The Working Group is not able to assess the impact on the biomass of catch levels in 2004 other than assuming average recruitment. The fishery in a given year is very dependent on that year's incoming year class; therefore a catch projection for 2004 assuming average recruitment is meaningless. If a TAC regime was necessary and the required data was available, a management approach including a mid-year revision of the TAC taking into account an estimate of incoming recruitment would have to be considered for sprat. Despite the short-comings of the exploratory assessment presented here there are indications that the stock is lightly exploited.

Attempts to assess this stock have demonstrated the need for a better sampling coverage for both length and age composition. There is also a need for better knowledge of spawning seasons and recruitment from a possible autumn spawning. There are indications that larvae from autumn spawning will over-winter as larvae and metamorphose the year after. As sprat is aged by counting winter-rings with reference to January 1 as the birthday this will result in incorrect allocation to year classes. The group recommends a review of the criteria used for ageing sprat and further validation of the formation of winter rings and allocation to year classes.

Table 8.1.1. Sprat in the North Sea. Catches (' 000 t) 1987-2003. Catch in fjords of western Norway excluded.
(Data provided by Working Group members except where indicated). These figures do not in all cases correspond to the official statistics and cannot be used for management purposes.

Figure 8.6.2. Predation mortality, average over 1 to 4 year-old sprat for the period 1963 - 2000 from MSVPA.

Figure 8.6.3. CSA model fits to the IBTS indices of recruits (1 year-old) and $2+, \mathrm{M}=0.7$.

Figure 8.6.4: sprat biomass and numbers-at-age estimated by CSA.

Figure 8.6.5: log-residuals from the model fit to the two stages, $\mathrm{M}=0.7$.

Figure 8.6.6. CSA estimated stock biomass, median and $95 \%$ confidence intervals for $\mathrm{M}=0.7$. Stock biomass estimate for $\mathrm{M}=0.8$ is shown as dotted line.

Figure 8.6.7. CSA biomass estimates, retrospective plot ( $\mathrm{M}=0.7$ )

Figure 8.7.1. Stock biomass projections for 2004 and 2005 under 2003 exploitation rate and median recruitment in 2005.

Figure 8.7.2. IBTS indicies versus the total catch (1987-2003). A fittet regression line to the data results in a R-square of 0.34. The arrow indicates the biomass index for 2004 (2183).
9.1 The fishery

### 9.1.1 ACFM advice applicable for 2003

The TAC for this fishery was set to $9,600 t$ for 2003 and $9,600 t$ for 2004 . No ACFM advice has been provided in recent years.

### 9.1.2 Catches in 2003

Table 9.1.1 shows the nominal landings in 1985-2003. The landings in 2003, as reported by UK (England and Wales), increased slightly in 2003 but were lower than the average for the period. The landings are commercial data from English and Welsh vessels landing into England and Wales. Monthly catches for the Lyme Bay sprat fishery in the period from 1991 to 2002 is shown in Table 9.1.2. Catches are mainly taken in the third and fourth quarter. No such information was available for the working group regarding catches from 2003.

### 9.1.3 Catch Composition

Catch compositions and the mean weights for 1991-1998 are given in Table 9.1.3. No samples of commercial catches have been available for the period 1999-2003.

Table 9.1.1 Divisions VIId,e, sprat. Nominal catch (t) in 1985-2003.

1 August to December only (samples in August and December only, so these are best estimates
2 August to December only (samples in August, September and November only so these are best estimates
3 Only September (one sample)

### 10.1 The Fishery

### 10.1.1 ACFM advice applicable for 2003 and 2004

The ACFM advice on sprat management is that exploitation of sprat will be limited by the restrictions imposed on fisheries for juvenile herring. This is a result of sprat being fished mainly together with juvenile herring. The sprat fishery is controlled by by-catch ceilings of herring as well as by-catch percentage limits. No ACFM advice on sprat TAC has been given in recent years. The sprat TAC for 2003 was $50,000 \mathrm{t}$, with a restriction on by-catches of herring not exceeding $21,000 \mathrm{t}$. For 2004 the same values were set as in 2003.

### 10.1.2 Landings

In 1997 a mixed-clupeoid fishery management regime was changed to a new agreement between the EU and Norway that resulted in a TAC for sprat as well as a by-catch ceiling for herring.

The total annual landings for Division IIIa by area and country are given in Table 10.1.1 for 1974-2003. The total landings decreased by approximately $10,000 \mathrm{t}$ from 2002 to 2003, and are the lowest since 1998.

The Norwegian and Swedish landings include the coastal and fjord fisheries. The Swedish coastal sprat fishery increased slightly in 2003.

Landings by countries and by quarter are shown in Table 10.1.2. For 2003 the landings were taken in all quarters with the bulk of the catch in the $1^{\text {st }}$ and $4^{\text {th }}$ quarter. In the second quarter $1,400 \mathrm{t}$ were landed. Denmark has a total ban on the sprat fishery in Division IIIa from May to September.

### 10.1.3 Fleets

Fleets from Denmark, Norway and Sweden carry out the sprat fishery in Division IIIa.
The Danish sprat fishery consists of trawlers using a 16 mm -mesh size codend and all landings are used for fishmeal and oil production. Some of the sprat landings from Denmark and Sweden are by-catches in the herring fishery using 32 mm mesh-size cod ends.

There is a Swedish fishery directed at sprat with by-catches of herring. There is also a fishery carried out with small purse seiners at the West Coast of Sweden for human consumption.

The Norwegian sprat fishery in Division IIIa is an inshore purse seine fishery for human consumption.

### 10.2 Biological Composition of the Catch

### 10.2.1 Catches in number and weight-at-age

The numbers and the mean weight-at-age in the landings from 1995 to 2003 are presented in Table 10.2.1 and Table 10.2.2, respectively. Landings, for which samples were collected, were raised using a combination of Swedish and Danish samples, without any differentiation in types of fleets. Quarterly and annual distributions of catches by rectangle are shown in Figures 8.1.1-8.1.2.

### 10.2.2 Quality of catch and biological data

Denmark reorganised and improved its monitoring system for management and scientific purposes in 1996. The required level of one sample per $1,000 \mathrm{t}$ landed was more than met in 2003 with 72 samples from a total landing of 10,840 tonnes.

Denmark has provided biological samples from all the quarters where there were landings in the Kattegat, but the Skagerrak was less intensely sampled. Sweden provided biological samples from the fishery in Skagerrak from all quarters except the $3^{\text {rd }}$ quarter and did not provide samples for any catches in the Kattegat. No Norwegian samples were collected.

The samples were used to estimate the numbers of sprat-at-age and the mean weight-at-age, in all sprat landings (Tables 10.2.1 and Table 10.2.2 respectively). The sample size ( 87 samples) has increased compared to the level in 2002 ( 75 samples). As in previous years, no samples of sprat were taken from the fisheries for human consumption. Therefore, data from the industrial landings were used for the estimation of numbers of sprat-at-age and the mean weight-at-age. Details on the sampling for biological data per country, area and quarter are shown in Table 10.2.3.

Acoustic estimates of sprat have been available from the ICES co-ordinated Herring Acoustic surveys since 1996. In 1996 the total estimate was $7.9 \times 10^{8}$ fish or 14,267 tonnes. About $95 \%$ of the biomass was recorded in Kattegat. There were very low estimates of sprat from 1997 to 2002, but the estimates increased in 2003 in Kattegat, where total biomass was estimated to be 13,000 tonnes. Again sprat was only encountered in the south eastern Kattegat (ICES 2004/G:05).

### 10.4 Mean weight-at-age

Mean weights-at-age (g) in the catches during 2003 are presented, by quarter, in Table 10.2.2. The table includes mean weights-at-age for 1995-2002 for comparison. These have been very variable over time, but whether this is due to actual variation in mean weight or difficulties in ageing of sprat is uncertain.

### 10.5 Recruitment

The IBTS (February) sprat indices for 1984-2004 are presented in Table 10.5.1. The IBTS data are provided by rectangle in Figure 8.3.1 for age groups 1, 2 and 3+, and the mean length ( mm ) of 1-ringer sprat in Figure 8.3.2. The indices are calculated as mean no. hr (CPUE) weighted by area where water depths are between 10 and 150 m (ICES 1995/Assess:13). The indices were revised in 2002 (ICES 2002/ACFM:12) based on an agreement in the IBTS WG in 1999, where it was decided to calculate the sprat index as an area weighted mean over means by rectangles for the IIIa (ICES 1999/D:2). The old time-series of IBTS indices (from 1984-2001) is shown in ICES 2001/ACFM:10.

The total IBTS index for 2004 is extremely low, the lowest in the series. The 2004 index for age-group 1, however, is in line with the IBTS index 2003 for the same age-group, but the index for the remaining age-groups ( $2-5+$ ) are considerable lower in 2004 than in any other year since 1990, especially age-group 2 . The reason for this is uncertain; the procedure for the 2004 survey did not differ from previous years, though, the amount of hauls in area 9 was lower than in previous years ( 7 hauls less than in 2003). Also there are still considerable difficulties in ageing of sprat from this area.

### 10.6 State of the Stock

No assessments of the sprat stock in Division IIIa have been presented since 1985 and this year is no exception. A Schaefer model was fit to the data in 1999 (ICES 1999/ACFM:12) but that attempt was not successful and was subsequently abandoned. Last year the Working Group agreed to explore the data for sprat in Division IIIa by means of Catch-Survey Analysis (CSA) as performed for sprat in the North Sea (ICES 2003/ACFM:17). The model fitting was poor, probably due to the highly variable IBTS recruitment index. CSA is not deemed to be an appropriate model for this stock and this year no effort was done to fit the data to CSA or any other model.

According to the IBTS (February)-index for 2003, the sprat stock in the area has decreased from last year and is now at the lowest level in the whole time-series.

### 10.7 Projection of Catch and Stock

There is no relationship between the IBTS (February) index (no./h) and the total catch in the same year $\left(\mathrm{r}^{2}=0.01\right)$-the data is shown in Figure 10.7.1-and the index was not considered useful for management of sprat in Division IIIa. The estimated yield for 2004 using the total IBTS index was 6,000 tonnes (Table 10.6.1) in a SHOT-estimate (Shepherd, 1991). This is the lowest estimated yield since 1990; however, this method is not considered to provide any reliable projection under the present management regime and the IBTS index is poor for this particular stock.

### 10.8 Reference Points

There are no reference points for this stock.

### 10.9 Management Considerations

Sprat in Division IIIa is short-lived with large inter-annual fluctuations in stock biomass. The natural inter-annual variability in stock abundance, mainly driven by recruitment variability, is high and does not appear to be strongly influenced by the observed levels of fishing effort.

The sprat has mainly been fished together with herring, except for 1994 and 1995 when a directed sprat fishery was carried out with low by-catches of herring. The human consumption fishery takes only a minor part of the total catch.

With the current management regime, where there are by-catch ceilings of herring as well as by-catch percentage limits, the sprat fishery is controlled by these factors. Attempts to assess this stock have demonstrated the need for:

- Improved sprat sampling for age data
- Development of a suitable biomass index
- Improvement of the ageing techniques

There is also a need for better knowledge of spawning seasons and possible recruitment from the North Sea stock.

Table 10.1.1 Division Illa sprat. Landings in ('000 t) 1974-2003.
(Data provided by Working Group members). These figures do not in all cases correspond to the official statistics and cannot be used for management purposes.
In the period from 1982 to 1992 Sweden only reported total catches from division IIla.

# ANNEX 1 <br> EXTENSION OF HISTORIC CATCH DATA FOR VIA NORTH 

Stephen Keltz and John Simmonds

FRS Marine Lab Aberdeen

## Introduction

Very high recruitment had been observed near the beginning of the current time series for VIa north, 1976-2002, and it was though that an extension of the time series might improve information on the stock dynamics. Prior to 1982 herring stocks in ICES Area VIa were assessed as one stock, along with the herring by-catch from sprat fishery in the Moray Firth.

In the 1982 working group report, and in subsequent years, Area VIa was split into a northern and a southern area at $56^{\circ} \mathrm{N}$ (ICES, 1982). This paper explores the data available for reconstructing catch data back to 1957 .

## Sources of Data.

The data used for this study has been sourced primarily from historic working group reports, and catch at age data by national fleets was obtained from historic paper records kept at FRS's Marine Laboratory.

## Catch in Tonnes.

The data for catches, in tonnes, by country from 1957 to 1973 for area VIa (Table 1) was taken from Table 4.6 in the Report of the Herring Assessment Working Group 1974 (ICES CM 1974/H:4). This table also included data from the juvenile herring by-catch from the Moray Firth sprat fishery. A minor correction carried out subsequently by the WG was included in the table presented here which has altered the 1972 total (see footnote below Table 1).

Catch by country for VIa and Moray Firth was extended forward to 1980 using data from Table 5.1 in the 1981 ICES Herring Assessment Working Group Report (CM 1981/H:8.(Table 2). This report confirmed the validity and stability of the last few years of data from the 1974 report, (1971 to 1972) and added data for the period 1974 to 1980.

In 1982 the WG carried out an analysis of catch at age data and split the VIa catches into VIa north and VIa south and combined the latter with data from VIIb. Tonnes of herring caught by country from 1971 to 1981 in Area VIa north (Table 3) were taken from Table 5.1 in the 1982 ICES Herring Assessment Working Report (CM 1982/Assess:7). The method used by the WG is not described in the WG report and cannot therefore be exactly duplicated today.

## Catch in Numbers.

The catch in numbers at age over the period, 1971 to 1980 for VIa north was taken from Table 5.2 in the 1982 Working Group Report (Table 4).

For the period 1976 to 2002, catch in numbers at age in VIa north, were available from the assessment files and reported in Table 5.2.2, in the 2003 ICES Report of the Herring Assessment Working Group (CM 2003/ACFM:17).Table 5.

The 1982 Working Group report gave a four year overlap into the 2003 Working Group report catch at age data (1976-1980) and these data matched, suggesting that the data from 1971 to 1975 was calculated on the same basis at the time it was constructed in 1982. Inspection of the intermediate reports suggested there was a practice of deleting data year by year as new data became available. This practice ceased in about 1987.

FRS Marine Laboratory archive contained a series of paper records of summarised catch in numbers at age for autumn spawning herring by national fleet from 1957 to 1972. (Table 6). These where believed to have been assembled in 1973/74, and used at the 1974 working group to calculate catch data for the whole of VIa.

The totals were similar but not identical to the data in Table 4.8 in the 1974 Working Group Report (Table 7).

## Mean Weights in the Catch.

Several sources of mean weights at age were examined for the period.
From 1976 to 2002 the data was taken from Table 5.6.3 in the 2003 Working group report (Table 8).
For earlier mean weights at age, working group reports from 1982 back to 1974 were examined. Table 9 lists the mean weights at age from each of those reports.

An ICES paper by Saville and Morrison (1973) referenced in the 1974 working group report was used for mean weights from 1957 to 1972 . Although mean weights were not explicitly tabulated. The values used were obtained by dividing the biomass at age by the stock numbers at age, Three years were tested and constant mean weights were found to have been used throughout the period (Table 10).

Data validation and Assembly

## Catches in Tonnes.

The fraction of fish caught in VIa north, from 1957 to 1975, was not explicitly available. However, the 1980 and 1981 Working G reports contained catches in tonnes by national fleet for whole of VIa and the following year, the 1982 WG report, contained data for the same period, and fleets, for VIa north only. These three sources of data were used to determine fleet fishing practices. Table 11 shows that with only a few exceptions most fleets fished exclusively in either VIa north or VIa south only. Using these fishing patterns National Fleet Factors (NFF) for catch in VIa north were obtained. The factors used are given at the base of Table 11. A comparison of two methods has been made for the three earliest years available, 1970 to 1972. Table 12 shows the results of this comparison expressed as the difference in total catch using NFF compared with the 1982 WG method. The WG method is not explicitly documented in the report. The difference is negligible. The proportion of the total catch that depends on fleet factors is shown in Table 13 by year from 1957 to 1971. On average less that $10 \%$ of catch uses fleet factors that differ from either unity or zero indicating that the precise magnitude of these factors is not particularly important. This total catch contains both spring and autumn spawners and reflects total catch taken in VIa north

The resulting total catch in tonnes, and proportion of autumn and spring spawning herring in the area by weight, is given in Figure 1. This indicates that the proportion of spring spawners caught decreased from around $30 \%$ in the early part of the period, to about $15 \%$ in the later part. Thus the by the 1970s it was no longer so important to differentiate between these different herring. Examination of the sample data for the acoustic survey in July 2003 in VIa north shows that that this survey detects about $10 \%$ juvenile, $85 \%$ Autumn spawning adults and only $5 \%$ spent herring which are probably spring spawners.

## Catch at Age.

## Catch at age from 1971-1975.

Catch at age from 1971 to 1975 for VIa north has been calculated by the WG in 1982 but then deleted year by year from the WG reports as new data was added, each report showing only the last 10 or 11 years of data. This procedure stopped in 1987 with the first year set at 1976. This catch at age data is taken directly as it is thought to be consistent with later data from 1976 to 1981 prepared at the 1982 WG and thus compatible with subsequent data used in 2003. Thus catch in the period 1971 to 2002 represents all herring caught in VIa north irrespective of whether this is autumn or spring spawning herring.

## Checks on validity of FRS Aberdeen numbers at age data by national fleet.

The quality of the fleet based data recorded in Aberdeen (Table 6) was tested against tabulated catch at age data for the period 1957 to 1970 presented in the 1974 WG report (Table 7). The total numbers at age were seen to be different for the sum of catch at age recorded at FRS Aberdeen but the total numbers by year agreed very closely. This suggested that the WG had reviewed the fleet data and reallocated some age keys, however, this process was not documented in the WG report. There was complete agreement for the period 1957 to 1961. Using Solver in excel a series of annual fleet multipliers were estimated for the 13 fleets independently by year for the years 1962 to 1972. This gives a total of 143 factors. The results of this showed a very clear pattern of reallocation of age structures. This pattern is summarised in Table 14 where the percentage of the total VIa catch reallocated and the change in allocation by country is shown. The differences are dominated by the decision to remove reported Irish age information and to substitute this by either Scottish or German data. Irish data was regarded as suspect for VIa. However, we will see later that all Irish catch with or without age keys is excluded from VIa north data using the NFF so this reallocation is not required when estimating VIa north catch at age. The remaining reallocation is only required for 1963, 1969 and 1971, each are less than $2 \%$ of the catch. This is thought to be negligible.

## The Validity of The Fleet Factors when allocating catch at age.

In 1982 the WG split VIa catch between VIa north (Table 4) and VIa south for the period 1971 to 1981. As indicated above the data for catch at age by national fleet for the whole of VIa was held on paper records in FRS Martine Laboratory in Aberdeen Scotland for the period 1957-1972 (Table 6) giving two years of overlap, $1971 \& 1972$. The splitting method described above to estimate catch by fleet in VIa north was tested on age data using the FRS fleet at age data and compared with the results presented at the 1982 WG for these two years. The Age structures can be compared in Figures 2a and 2b for 1971 and 1972 respectively. These age structures are sufficiently similar to give
confidence to both the records retained at FRS Aberdeen but also the simple fleet factor method proposed to split the catch and allocate age structures.

## Final selection of catch at age data.

The catch at age assembled in 1982 for the period 1973 to 1975 is of a similar quality to the data currently in use from 1976 and can be used directly. There are two possible methods of obtaining catch at age for 1971 and 1972. The fleet based method produces a lower SOP correction and has been selected for these two years

The data 1957-1972 data held in Aberdeen is very similar to that used at the 1981 WG the only major difference is the exclusion of Irish fleet catch at age data. However, in constructing VIa north data the Irish data is excluded anyway and its quality is not relevant. By using fleet factors it is possible to allocate age proportions reasonably accurately for 1971 and 1972 suggesting the fleet procedure is adequate for the period. Catch at age for autumn spawning herring for 1957 to 1972 can be constructed for VIa north autumn spawning herring with some confidence (Table 15).

This leaves two options, direct estimation of autumn spawning herring or raising to total catch by setting SOP values to unity. The first may underestimate the productivity in the past relative to today. The latter may overestimate past productivity as the spring spawning component today is thought to be smaller than the part in the past.

## Mean Weight at Age

A full mean weights at age table was constructed directly from data used by WG to give mean weights at age (Table 16). Data for 1957 to 1972, were temporally invariate and obtained from Saville and Morrison (1973). The mean weights at age from 1973 to 1976 were calculated from the mean of two years data 1974 and 1975 weights at age (taken from 1976 working group report). For $1974 \& 5$ the mean was chosen in preference to individual annual values as the sum of products was further from unity using these values than using the mean weights presented in the 1976 report. The same values have also been used from 1976 to and including 1981. Subsequent data was the same as the 2003 WG report. Thus from 1975 onwards there is no change in the data.

## Appendix 2 - Stock Annex

Stock specific documentation of standard assessment procedures used by ICES.

Stock: North Sea Autumn Spawning Herring (NSAS)<br>Working Group: Herring Assessment WG for the Area south of $62^{\circ} \mathrm{N}$<br>Date: 18 March 2004<br>Authors: C. Zimmermann (ed.), J. Dalskov, M. Dickey-Collas, H. Mosegaard, P. Munk, J. Nichols, M. Pastoors, N. Rohlf, E.J. Simmonds, D. Skagen

#### Abstract

A. General A.1. Stock definition: Autumn spawning herring distributed in ICES area IV, Division IIIa and VIId. Mixing with other stocks occurs especially in Division IIIa (with Western Baltic Spring Spawning herring). A.2. Fishery: North Sea Autumn Spawners are exploited by a variety of fleets, ranging from small purse seiners to large freezer trawlers, of different nations (Norway, Denmark, Sweden, Germany, The Netherlands, Belgium, France, UK, Faroe Islands). The majority of the fishery takes place in the Shetland-Orkney area in the $2^{\text {nd }}$ and $3^{\text {rd }}$ quarter, and in the English Channel (Division VIId) in the $4^{\text {th }}$ quarter. Juveniles are caught in Division IIIa and as by-catch in the industrial fishery in the central North Sea. For management purposes, 4 fleets are currently defined: Fleet A is harvesting herring for human consumption in IV and VIId, but includes herring by-catches in the Norwegian industrial fishery; fleet B is the industrial (small mesh, $<32 \mathrm{~mm}$ mesh size) fleet of EU nations operating in IV and VIId. North Sea Autumn spawners are also caught in IIIa in fleets C (human consumption) and D (small mesh).

## A.3. Ecosystem aspects:

Herring is the key pelagic species in the North Sea and is thus considered to have major impact as prey and predator to most other fish stocks in that area.

The North Sea is semi-enclosed and situated on the continental shelf of North-western Europe and is bounded by England, Scotland, Norway, Sweden, Denmark, Germany, the Netherlands, Belgium and France. It covers an area of $745,950 \mathrm{~km}^{2}$ of which the greater part is shallower than 200 m . It is one of the most diverse coastal regions in the world, with a variety of coastal habitats (fjords, estuaries, deltas, banks, beaches, sandbanks and mudflats, marshes, rocks and islands), and four ecological seasons. It is a highly productive ( $>300 \mathrm{gC} \mathrm{m}^{-2} \mathrm{yr}^{-1}$ ) ecosystem but with primary productivity varying considerably across the sea. The highest values of primary productivity occur in the coastal regions, influenced by terrestrial inputs of nutrients, and in areas such as the Dogger Bank and tidal fronts. Changes observed in trophic structure are indicative of a trend towards a decreasing resilience of this ecosystem. This trend is partially a response to inter-annual changes in the physical oceanography of the North Atlantic.

Herring are an integral and important part of the pelagic ecosystem in the North Sea. As plankton feeders they form an important part of the food chain up to the higher trophic levels. Both as juveniles and as adults they are an important source of food for some demersal fish and for sea mammals. Over the past century the top predator, man, has exerted the greatest influence on the abundance and distribution of herring in the North Sea. Spawning stock biomass has fluctuated from estimated highs of around 4.5 million tonnes in the late 1940s to a lows of less than 100,000 tonnes in the late 1970s. The species has demonstrated a robustness in relation to recovery from such low levels once fishing mortality is curtailed in spite of recruitment levels being adversely affected.

Their spawning and nursery areas, being near the coasts, are particularly sensitive and vulnerable to anthropogenic influences. The most serious of these is the ever increasing pressure for marine sand and gravel extraction. This has the
potential to seriously damage and destroy the spawning habitat and disturb spawning shoals and destroy spawn if carried out during the spawning season. Similarly, trawling at or close to the bottom in known spawning areas can have the same detrimental effects. It is possible that the disappearance of spawning on the western edge of the Dogger bank could well be attributable to such anthropogenic influences.

In more recent years the oil and gas exploration in the North Sea has represented a potential threat to herring spawning although great care has been taken by the industry to restrict their activities in areas and at times of known herring spawning activity.

## By-catch and Discard

By-catch consists of the retained 'incidental' catch of non-target species and discard is a deliberately (or accidentally) abandoned part of the catch returned to the sea as a result of economic, legal, or personal considerations. This section therefore deals with these two elements of the fishery, looking specifically at fishery-related issues. Cetacean, seabird and other threatened, rare and iconic species which may form part of a by-catch are considered separately in the next section.

Incidental Catch: The incidental catch of non-target species in the North Sea pelagic herring fishery in general is considered to be low. A recent study (Pierce et al, 2002) investigated incidental catch from commercial pelagic trawlers over the period January to August 2001. The target species, herring, accounted for $98 \%$ by weight of the overall catch with an overall incidental catch of $2.3 \%$. Mackerel, which are known to occur in mixed schools with herring in division IVa was the main by-catch species, accounting for $69 \%$ of by-catch by weight. Haddock ( $25.7 \%$ of by-catch by weight), horse mackerel Trachurus trachurus ( $4.8 \%$ ) and whiting Merlangius merlangus $(0.4 \%)$ were all present in samples. However, onboard sampling over 2002 by Scottish and German observers found substantial discards of herring, taken as by-catch in the mackerel fishery over the 3 rd and 4th quarters, after herring quotas had been exhausted.

Discards and slipping: The indications are that large-scale discarding is not widespread in the directed North Sea herring fishery. A number of direct-observer surveys have recently been conducted on Scottish and Norwegian pelagic trawlers, based on observation of 222 hauls catching 9,889 tonnes fish (Napier et al, 2002) over 2000-2002. The overall discard rate was $4.2 \%$, although that from pelagic trawlers of $6.6 \%$ was substantially higher than that from pursers ( $0.6 \%$ ). These discard rates were higher than the overall figure of $2.8 \%$ recorded in an earlier study (Napier et al, 1999) which were evenly distributed between pursers and trawlers. This indicates that the different discard rates between the different fishing types in the later study were more a function of fishing location and stock size compositions rather than any gear-specific size selectivity. Some discarding, in the form of wastage (i.e. fish left meshed in the net or in the cod-end of trawls), was associated with almost all pelagic catches but the actual quantities of fish involved were low ( $2 \%$ of total discarded fish). In both studies by Napier et al., most of the observed discarding occurred through slipping, i.e. opening the net and releasing the fish before they were pumped on-board. This occurred when catch volumes were too small, or the size of fish was too small or the fish were poor in quality. For both pursers and trawlers 'poor' fish quality was a significant cause of discarding. The size of the catch was also a significant cause of discarding from trawlers, either because the catch was too small or too large, with boats either discarding a small proportion or all of the catch. The recent influence of strong herring year classes was apparent in the composition of discards with smaller, younger fish accounting for a high proportion of the fish discarded in 2001. However surveys on the reasons why vessels discarded fish showed that larger discarding events (i.e. those $>500 \mathrm{~kg}$ ) were equally likely to the fish being of poor quality (trawlers) or the catch exceeded the vessel's capacity or market requirements (pursers). No data on survival of discarded fish has been collected but it is considered likely that mortality rates will be significant.

Ecosystem Considerations. The incidental non-target fish catch by directed North Sea herring fisheries appears to be low (ca. $2 \%$ ), mainly consisting of mackerel when fishing mixed shoals. This infers that the ecosystem level implications of incidental fish catches are negligible. The discard of unwanted herring, mostly in the form of highgrading to improve catch quality and grade sizes of fish between 2-4 years of age (see Section above) is also low, being around 3,250 tonnes (2000) and 750 tonnes (2001) for the Scottish and Norwegian and Scottish pursers and refrigerated seawater tank (RSW) pelagic trawlers operating in ICES division IVa. For both years, this was equivalent to about $10.4 \%$ by weight of the total landings. Of more concern are discards of herring from other pelagic fisheries, especially that for mackerel, where more substantial discarding of herring occurs when quotas for herring are exhausted. National reports to ICES over 1996 to 2002 suggest that total herring discards have varied between 1,500 tonnes to an unprecedented 17,000 tonnes in 2002 (reflecting onboard sampling by Scotland and Germany that observed substantial discards of herring in the mackerel fishery in the 3rd and 4th quarter in Division IVa (W)). Assuming a distribution and yield of the international mackerel fishery in IVa in 2002 to be similar to that in 2001, herring discards of all fleets could be as high as $50,000 \mathrm{t}$. This would increase the total catch in the North Sea by almost $15 \%$ and would certainly have an influence on the North Sea autumn spawning stock assessment and the perception of stock size. Discarding
behaviour appears to have changed again in 2003, when herring TAC has been increased by $50 \%$, and at the same time the mackerel TAC has been reduced by more than $5 \%$.

Interactions with Rare, Protected or Icon Species: Interactions between the directed North Sea herring fishery with rare, protected or icon species are, in general, considered to be exceptional. Species which may interact with the fishery are considered below.

Cetacean by-catch: Since 2000, the Sea Mammal Research Unit (SMRU) of St. Andrew's University in Scotland, under contract to DEFRA, has carried out a number of surveys to estimate the level of by-catch in UK pelagic fisheries. SMRU, in collaboration with the Scottish Pelagic Fishermen's Association, placed observers on board thirteen UK vessels for a total of 190 days at sea, covering 206 trawling operations around the UK. To date, no cetacean by-catch has been observed in the herring pelagic fishery in the North Sea. There is currently an ongoing observer programme in the UK monitoring cetacean by-catch rates in pelagic trawl fisheries with results due at the end of September 2003 and it is understood that this confirms that cetacean by-catch by the pelagic trawl fishery is negligible (Northridge, pers. comm.). Pierce (2002) also reports that no by-catches of marine mammals were observed over 69 studies hauls and considers that the underlying rate for marine mammals in the pelagic fisheries studies (pelagic trawls in IVa and VIa) is no more than 0.05 (i.e. five events per 100 hauls) and may well be considerably lower than this.

Other than the above, there are no reliable estimates of by-catch for pelagic trawl fisheries, though observations have been made and by-catch rates have been established for several fisheries. Kuklik and Skóra (2003) refer to a single record of a harbour porpoise (Phocoena phocoena) bycaught in a herring trawl in the Baltic. Observations in several other pelagic trawl fisheries were reported by Morizur et al. (1999) and Couperus (1997). All appear to agree that incidental catches of cetaceans in the Dutch pelagic trawl fishery are largely restricted to late-winter/early-spring in an area along the continental slope southwest of Ireland.

On 24 July 2003 the European Commission issued a proposal for a Council Regulation to address the problem of cetacean by-catch in various fisheries. For the North Sea (ICES IV) $5 \%$ of pelagic trawl fisheries would have to be monitored by observers. In the eastern channel $5 \%$ of pelagic trips would have to be monitored from April to November but $10 \%$ from December to March. The Commission has asked the Council to adopt this proposal by 1 July 2004.

Seal by-catch: The by-catch of seals in directed pelagic herring fishery in the North Sea is reported to be "very rare" (Aad Jonker, pers. comm.). Independent verification also confirms this to be so, with perhaps one animal being caught by the whole North Sea fleet a year (Bram Couperus (RIVO), pers. comm.). Northridge (2003) observed 49 seals taken in 312 pelagic trawl tows throughout UK waters and reports that the fishery in North-western Scotland has the highest observed seal by-catch levels of UK pelagic trawl fisheries, possible amounting to dozens per year. Although not confirmed, it was assumed that the majority were grey seal Halichoerus grypus. This species is mainly distributed around the Orkneys and Outer Hebrides - out of a UK population of 129,000, only around 7,000 and 5,900 are distributed off the Scottish and English North Sea coasts respectively (SCOS, 2002), and so by-catch rates in the North Sea are likely to be substantially less than off the NW Scottish coast. The eastern Atlantic population of the Grey seal is not considered to be threatened.

Other by-catch: Sharks are occasionally caught by pelagic trawlers in the North Sea, although this is rare with a maximum of two fish per trip (Aad Jonker, pers. comm.). Survival rates are apparently high, with sharks being released during or after the cod-end is being emptied. The species are unknown, although blue shark Prionace glauca, which preys primarily upon schooling fishes such as anchovies, sardines, herring, are known to have been caught by pelagic trawls off the SW English coast (Bram Couperus (RIVO), pers. comm.). Gannets (Morus bassanus), which frequently dive at and around nets, were observed by Napier et al. (2002) entangled in the nets but were not present in samples. Actual mortality rates of caught gannets have not been assessed in detail, and some have been observed alive after release from the gear. An extrapolation from observed mortalities corresponds to around 560 gannet deaths per year, although this is based on a relatively low sample frame. Seabird by-catch in the North Sea is considered to be comparatively rare compared to the NW Scotland where 1-3 birds may be caught, esp. in grounds off St. Kilda (Aad Jonker (former freezer trawler skipper), pers. comm.). RIVO observers in the North Sea only recorded one incident of seabird by-catch over 10 trips (Bram Couperus (RIVO), pers. comm.).

## B. Data

## B.1. Commercial catch:

Commercial catch is obtained from national laboratories of nations exploiting herring in the North Sea. Since 1999 (catch data 1998), these labs have used a spreadsheet to provide all necessary landing and sampling data, which was developed originally for the Mackerel Working Group (WGMHSA) and further adapted to the special needs of the

Herring Assessment Working Group. The current version used for reporting the 2003 catch data was v1.6.4. The majority of commercial catch data of multinational fleets was provided on these spreadsheets and further processed with the SALLOCL-application (Patterson, 1998). This program gives the needed standard outputs on sampling status and biological parameters. It also clearly documents any decisions made by the species co-ordinators for filling in missing data and raising the catch information of one nation/quarter/area with information from another data set.

Transparency of data handling by the Working Group. The current practice of data handling by the Working Group is that the data received by the co-ordinators is available in a folder called "archive". These high-resolution data are not reproduced in the report. The archived data contains the disaggregated dataset (disfad), the allocations of samples to unsampled catches (alloc), the aggregated dataset (sam.out) and (in some cases) a document describing any problems with the data in that year.

Current methods of compiling fisheries assessment data. The species co-ordinator is responsible for compiling the national data to produce the input data for the assessments. In addition to checking the major task involved is to allocate samples of catch numbers, mean length and mean weight-at-age to unsampled catches. There are at present no defined criteria on how this should be done, but the following general process is implemented by the species co-ordinators. Searches are made for appropriate samples by gear (fleet) area quarter, if an exact match is not available the search will move to a neighbouring area if the fishery extends to this area in the same quarter. More than one sample may be allocated to an unsampled catch, in this case a straight mean or weighted mean of the observations may be used. If there are no samples available the search will move to the closest non-adjacent area by gear (fleet) and quarter, but not in all cases.

The Working Group acknowledges the effort some members have made to provide "corrected" data, which in some cases differ significantly from the officially reported catches. Most of this valuable information is gathered on the basis of personal knowledge of the fishery and good relations between the scientist responsible and the fishermen. The WG is aware of the problem that this knowledge might be lost if the scientist leaves, and asks the national laboratories to ensure continuity in data provision. In addition the Working Group recognises and would like to highlight the inherent conflict of interest in obtaining details of unallocated catches by country and increasing the transparency of data handling by the Working Group. This issue will have to be carefully considered in light of any future development by ICES of a standard platform to store all fisheries disaggregated data, particularly with regard to confidentiality.

The WG considered the need of a long-term data storage for commercial catches and sampling, and the documentation of any primary data processing of these data. From 2000 on (catch data for 1999), the latest (consistency checked) versions of the input files together with standard outputs and a documentation of filling-in decisions made by the co-ordinators, ideally in the SALLOC-formats, are stored in a separate "archive" folder. This is updated annually, and the complete collection (which is supposed to be kept confidential as it will contain data on misreporting and unallocated catches) will be available for WG members on request. As there was very little historical information available, WG members were asked to provide as much as possible national catch and historical data sets in any available format which is then stored in a " historic" folder within "Archive". They will be consistency checked and transferred into a database system as soon as this is available.

## B.2. Biological

Catch-at-age data (catch numbers-at-age, mean weights-at-age in the catch, mean length-at-age) is derived from the raised national figures received from the national laboratories. The data is obtained either by market sampling or by onboard observers, and processed as described above. For information on recent sampling levels and nations providing samples, see Sec. 2.2. of the most recent HAWG report.

Mean weights-at-age in the stock and proportions mature (maturity ogive) are derived from the June/July international acoustic survey (see next paragraph).

## B.3. Surveys

## B.3.1 Acoustic: ICES Co-ordinated Acoustic Surveys for herring in North Sea, Skagerrak and Kattegat

The ICES Coordinated acoustic surveys started in 1979 around Orkney and Shetland with first major coverage in 1984. An index derived from that survey has been used in assessments since 1994 with the time-series data extending back to 1989. The survey was extended to IIIa to include the overlapping Western Baltic spring spawning stock in 1989, and the index has been used with a number of other tuning indices since 1991. The early survey had occasionally covered VIa (North) during the 1980s and was extended westwards in 1991 to cover the whole of VIa (North) annually since 1991,
and provides the only tuning index for VIa (North) herring, By carrying out the co-ordinated survey at the same time from the Kattegat to South of the Hebrides all herring in these areas are covered simultaneously, reducing uncertainly due to area boundaries as well as providing input indices to three distinct stocks. The surveys are co-ordinated under ICES Planning Group for Herring Surveys ICES PGHERS.

At present, six surveys are carried out during late June and July covering most of the continental shelf north of $52^{\circ} \mathrm{N}$ in the North Sea and to the west of Scotland to a northern limit of $62^{\circ} \mathrm{N}$. The eastern edge of the survey area is bounded by the Norwegian and Danish, Swedish and German coasts, and to the west by the shelf edge between 200 and 400 m depth. The surveys are reported individually in the report of the planning group for herring surveys, and a combined report is prepared from the data from all surveys. The combined survey results provide spatial distributions of herring abundance by number and biomass at age by statistical rectangle; and distributions of mean weight and fraction mature at age.

The acoustic recordings are carried out using Simrad EK60, EK500 and EY500 38 kHz sounder echo-integrator with transducers mounted on the hull, drop keel or towed bodies. Further data analysis is carried out using either BI500, Echoview or Echoann software. The survey track is selected to cover the area giving a basic sampling intensity over the whole area based on the limits of herring densities found in previous years. A transect spacing of 15 nautical miles is used in most parts of the area with the exception of some relatively high density sections, east and west of Shetland, in the Skagerrak where short additional transects were carried out at 7.5 nmi spacing, and in the southern area where a 30 nmi transect spacing is used.

The following target strength to fish length relationships have been used to analyse the data:
herring

$$
\begin{aligned}
& \mathrm{TS}=20 \log \mathrm{~L}-71.2 \mathrm{~dB} \\
& \mathrm{TS}=20 \log \mathrm{~L}-71.2 \mathrm{~dB} \\
& \mathrm{TS}=20 \log \mathrm{~L}-67.5 \mathrm{~dB} \\
& \mathrm{TS}=21.7 \log \mathrm{~L}-84.9 \mathrm{~dB}
\end{aligned}
$$

sprat

Data is reported through standardised data exchange format and combined at FRS Marine Lab Aberdeen. The exchange format currently holds information on the ICES statistical rectangle level, with at least one entry for each rectangle covered, but more flexible strata are accommodated by allowing multiple entries for abundance belonging to different strata. Data submitted consists of the ICES rectangle definition, biological stratum, herring abundance by proportion of Autumn spawners (North Sea and VIa North) and Spring spawners (Western Baltic, age and maturity, and survey weight (survey track length). Data are be presented according to the following age/maturity classes: 1 immature (maturity stage 1 or 2 ), 1 mature (maturity stage $3+$ ), 2 immature, 2 mature, 3 immature, 3 mature, $4,5,6,7,8,9+$. In addition to proportions at age data on mean weights and mean length are reported at age/maturity by biological strata. Data is combined using an effort weighted mean based on survey effort reported as number of nautical miles of cruise track per statistical rectangle. A combined survey report is produced annually. Apart from the Biomass index for 1-9+ringers, mean weights at age in the catch and proportions mature are derived from the survey to be used in the NSAS assessment.

## B.3.2 International Bottom Trawl Survey:

The International Bottom Trawl Survey (IBTS) started out as a Young Herring Survey (IYHS) in 1966 with the objective of obtaining annual recruitment indices for the combined North Sea herring stocks. It has been carried out every year since, and it was realized that the survey could provide recruitment indices not only for herring, but for roundfish species as well. Examination of the catch data from the 1st quarter IBTS showed that these surveys also gave indications of the abundances of the adult stages of herring, and subsequently the catches have been used for estimating $2-5+$ ringer abundances. The surveys are carried out in $1^{\text {st }}$ quarter (February) and in $3^{\text {rd }}$ quarter (August-September) using standardized procedures among all participants. The standard gear is a GOV trawl, and at least two hauls are made in each statistical rectangle.

In 1977 sampling for late stage herring larvae was introduced at the IBTS $1^{\text {st }}$ quarter, using Isaccs-Kidd Midwater trawls. These catches appeared as a good indicator of herring recruitment, however examination of IKMT performance showed deficiencies in its catchability for herring larvae, and a more applicable gear, a ring net (MIK) was suggested as an alternative gear. Hence, gear type was changed in the mid 90 'ies, and the MIK has been the standard gear of the program since. This ring net is of 2 meter in diameter, has a long two-legged bridle, and is equipped with a black netting of 1.5 mm mesh size. Oblique hauls are made during night in at least two statistical rectangles.

Indices of 2-5+ ringer herring abundances in the North Sea ( $\mathbf{1}^{\text {st }}$ quarter). Fishing gear and survey practices were standardised from 1983, and herring abundance estimates of 2-5+ ringers from 1983 onwards has shown the most
consistent results in assessments of these age groups. This series is used in North Sea herring assessment. The catches in DivisionIIIa is not included in this index. Table 2.3.3.1 in the HAWG report shows the time series of abundance estimates of 2-5+ ringers from the 1st quarter IBTS for the whole period.

Index of 1-ringer recruitment in the North Sea ( $1^{\text {st }}$ quarter). The 1-ringer index of recruitment is based on trawl catches in the entire survey area, hence, all 1-ringer herring caught in Div IIIa is included in this index. Indices are calculated as an area weighted mean over means by ICES statistical rectangle, and are available for year classes 1977 to recent (Table 2.3.3.3 of HAWG report). The Downs herring hatch later than the other autumn spawned herring and generally appears as a smaller sized group during the 1st quarter IBTS. A recruitment index of smaller sized 1-ringers is calculated using the standard procedure, but solely based on abundance estimates of herring $<13 \mathrm{~cm}$ (see discussion of procedures in earlier reports (ICES CM 2000/ ACFM:10, and ICES CM 2001/ ACFM:12).

MIK index of 0-ringer recruitment in the North Sea ( $\mathbf{1}^{\text {st }}$ quarter). The MIK catches of late stage herring larvae is used to calculate and 0-ringer index of autumn spawned herring in the North Sea. A flowmeter at the gear opening is used for estimation of volume filtered by the gear, and using this information together with information on bottom depth, the density of herring larvae per square meter is estimated. A mean herring density in statistical rectangles is raised to mean within subareas, and based on areas of these subareas an index of total abundance is estimated (see also ICES 1996/Asses:10). The series of estimates for subareas as well as the total index are shown in the actual report's Table 2.3.3.4.

## B.3.3. Larvae:

Surveys of larval herring have a long tradition in the North Sea. Sporadic surveys started around 1880, and available scientific data goes back to the middle of the 20th century. The co-ordination of the International Herring Larvae Surveys in the North Sea and adjacent waters (IHLS) by ICES started in 1967, and from 1972 onwards all relevant data are achieved in a data base. The surveys are carried out annually to map larval distribution and abundance. Larval abundance estimates are of value as relative indicators of the herring spawning biomass in the assessment.

Nearly all countries surrounding the North Sea have participated in the history of the IHLS. Most effort was undertaken by the Netherlands, Germany, Scotland, England, Denmark and Norway. A number of other nations have contributed occasionally. A sharp reduction in ship time and number of participating nations occurred in the end of the 1980s. Since 1994 only the Netherlands and Germany contribute to the larvae surveys, with one exception in 2000 when also Norway participated.

Larvae Abundance Index (LAI): The total area covered by the surveys is divided into 4 sub areas corresponding to the main spawning grounds. These sub areas have to be sampled in different given time intervals. The sampling grid is standardized and stations are approximately 10 nautical miles apart. The standard gear is a GULF III sampler or one of its national modifications. Newly hatched larvae less than 10 mm total length ( 11 mm for the Southern North Sea) are used in the index calculation. To estimate larval abundance, the mean number of larvae per square meter obtained from the Ichthyoplankton hauls is raised to rectangles of $30 \times 30$ nautical miles and the corresponding surface area. These values are summed up within the given unit and provide the larval abundance per unit and time interval.

Multiplicative Larval Abundance Index (MLAI): The traditional LAI and LPE (Larval Production Estimates) rely on a complete coverage of the survey area. Due to the substantial decline in ship time and sampling effort since the end of the 80 s, these indices could not be calculated in their traditional form since 1994. Instead, a multiplicative model was introduced for calculating a Multiplicative Larvae Abundance Index (MLAI, Patterson \& Beveridge, 1995). In this approach the larvae abundances are calculated for a series of sampling units. The total time series of data is used to estimate the year and sampling unit effects on the abundance values. The unit effects are used to fill unsampled units so that an abundance index can be estimated for each year.

Calculation of the linearised multiplicative model was done using the equation:

$$
\ln (\text { Indexyear,LAI unit })=\text { MLAIyear }+ \text { MLAI }_{\text {LAI }} \text { unit }+ \text { uyear, LAI unit }
$$

where MLAIyear is the relative spawning stock size in each year, $\mathrm{MLAI}_{\mathrm{LAI}}$ unit are the relative abundances of larvae in each sampling unit and year, LAI unit are the corresponding residuals. The unit effects are converted such that the first sampling unit is used as a reference (Orkney/Shetland 01-15.09.72) and the parameters for the other sampling units are redefined as differences from this reference unit. The model is fitted to abundances of larvae less than 10 mm in length ( 11 mm for SNS). The MLAI is updated annually and represent all larval data since 1972 . The time series is used as a biomass index in the herring assessment.
B.4. Commercial CPUE Not used for pelagic stocks.

## B.5. Other relevant data

## B.5.1 Separation of North Sea Autumn Spawners and IIIa-type Spring Spawners

North Sea Autumn Spawners and IIIa-type Spring Spawners occur in mixtures in fisheries operating in Divisions IIIa and IVaE (ICES, 1991/Assess:15): mainly 2+ ringers of the Western Baltic spring-spawners and 0-2-ringers from the North Sea autumn-spawners, including winter-spawning Downs herring. In addition, several local spawning stocks have been identified with a minor importance for the herring fisheries (ICES, 2001/ACFM 12).

The method of separating herring in Norwegian samples, using vertebral counts as described in former reports of this Working Group (ICES 1990/ Assess:14) assumes that for autumn spawners, the mean vertebral count is 56.5 and for Spring spawners 55.80 . The fractions of spring spawners (fsp) are estimated from the formula (56.50-v)/(56.5-55.8), where v is the mean vertebral count of the (mixed) sample with the restriction that the proportion should be one if $\mathrm{fsp}>=1$ and zero if $\mathrm{fsp}<=0$. The method is quite sensitive to within-stock variation (e.g. between year classes) in mean vertebral counts.

Experience within the Herring Assessment Working Group has shown that separation procedures based on size distributions often will fail. The introduction of otolith microstructure analysis in 1996-97 (Mosegaard and PoppMadsen, 1996) enables an accurate and precise split between three groups, autumn, winter and spring-spawners; however, different populations with similar spawning periods are not resolved with the present level of analysis. Different stock components that are not easily distinguished by their otolith microstructure (OM), are considered to have different mean vertebral counts (vs) as, e.g., winter-spawning Downs herring: 56.6 (Hulme, 1995), and the small local stocks, the Skagerrak winter/spring-spawners: 57 (Rosenberg and Palmén, 1982). Further, the estimated stock specific mean vs count varies somewhat among different studies; North Sea: 56.5, Western Baltic Sea: 55.6 (Gröger and Gröhsler, 2001) and North Sea: 56.5, Western Baltic Sea: 55.8 (ICES 1992/H:5). Comparison between separation methods using frequency distributions of vertebral counts and otolith microstructure showed reasonable correspondence. Using this information the years from 1991 to 1996 was reworked in 2001, applying common splitting keys for all years by using a combination of the vertebral count and otolith microstructure methods (ICES, 2001/ACFM:12). From 2001 and onwards, the otolith-based method only has been used for the Division IIIa.

Different methods of identifying herring stocks in the Division IIIa and Subdivisions 22-24 were recently evaluated in a EU CFP study project (EC study 98/026). The study involved several inter-calibration sessions between microstructure readers in the different laboratories involved with the WBSS herring. After the study was finished a close collaboration concerning reader interpretations has been kept between the Danish and Swedish laboratories. Sub-samples of the 2002 and 2003 Danish, Swedish, and German microstructure analyses were double-checked by the same Danish expert reader for consistency in interpretation. The overall impression is an increasingly good agreement among readers.

New molecular genetic approaches for stock separation are being developed within the EU-FP5 project HERGEN (EU project QLRT 200-01370). Sampling of spawning aggregations during spring, autumn and winter has been carried out in 2002 and in 2003 in Division IIIa and in the Western Baltic at more than 10 different locations. Preliminary results point at a substantial genetic variation between North Sea and Western Baltic herring.

After the introduction of otolith microstructure analysis in 1996 it was discovered that in the western Baltic a small percentage of the herring landings might consist of autumn-spawners individuals. Before molecular genetic methods became available for Atlantic herring the existence of varying proportions of autumn spawners in Subdivisions 22-24 in different years was considered a potential problem for the assessment.

## C. Historical Stock Development

## Model used:

Details on input parameters and model setup for the final ICA assessment are presented in Table 2.6.2.1. of the most recent HAWG report. The assessment has the same set-up and basic assumption as the assessment that was carried out last year. Input data are given in Tables 2.6.2.2. The ICA program operates by minimising the following general objective function:

$$
\sum \lambda_{c}(C-\hat{C})^{2}+\sum \lambda_{i}(I-\hat{I})^{2}+\sum \lambda_{r}(R-\hat{R})^{2}
$$

which is the sum of the squared differences for the catches (separable model), the indices (catchability model) and the stock-recruitment model.

The final objective function chosen for the stock assessment model was:

$$
\begin{aligned}
& \sum_{a=0, y=1997}^{a=8, y=2002} \lambda_{a}\left(\ln \left(\hat{C}_{a, y}\right)-\ln \left(C_{a, y}\right)\right)^{2}+ \\
& \sum_{y=1979}^{y=2002} \lambda_{\text {mlai }} \cdot\left(\ln \left(q_{m l a i} \cdot S \hat{S} B_{y}^{K}\right)-\ln \left(M L A I_{y}\right)\right)^{2}+ \\
& \sum_{a=5, y=1983 * *}^{a=5+, y=203} \lambda_{a, i b t s a}\left(\ln \left(q_{a, i b t s a} \cdot \hat{N}_{a, y}\right)-\ln \left(I B T S_{a, y}\right)\right)^{2}+ \\
& \sum_{a=9, y=1989}^{a=9+, y=2002} \lambda_{a, a c o u s t}\left(\ln \left(q_{a, a c o u s t} \cdot \hat{N}_{a, y}\right)-\ln \left(A C O U S T_{a, y}\right)\right)^{2}+ \\
& \sum_{y=1977}^{y=2003} \lambda_{m i k}\left(\ln \left(q_{m i k} \cdot \hat{N}_{0, y}\right)-\ln \left(M I K_{y}\right)\right)^{2}+ \\
& \sum_{y=1960}^{y=2002} \lambda_{s s r}\left(\ln \left(\hat{N}_{0, y+1}\right)-\ln \left(\frac{\alpha S \hat{S} B_{y}}{\beta+S \hat{S} B_{y}}\right)\right)^{2}
\end{aligned}
$$

** except for 1 ring IBTS which runs from 1979 to 2002
with the following variables:

| a,y | age (rings) and year |
| :--- | :--- |
| C | Catch at age (rings) |
| $\hat{C}$ | Estimated catch at age (rings) in the separable model |
| $\hat{N}$ | Estimated population numbers |
| $S \hat{S} B$ | Estimated spawning stock size |
| MLAI | MLAI index (biomass index) |
| ACOUST | Acoustic index (age disaggregated) |
| IBTS | IBTS index (1-5+ ringers) |
| MIK | MIK index (0-ringers) |
| q | Catchability |
| k | power of catchability model |
| $\alpha, \beta$ | parameters to the Beverton stock-recruit model |
| $\lambda$ | Weighting factor |

Software used: ICA (Patterson, 1998; Needle, 2000)
Model Options chosen:
Input data types and characteristics:

| Type | Name | Year range | Age <br> range | Variable from year to <br> year <br> Yes/No |
| :--- | :--- | :--- | :--- | :--- |
| Caton | Catch in tonnes |  |  |  |
| Canum | Catch at age in numbers | $1960-2002$ | $1-9+$ | Yes |

| Tuning fleet 4 | MLAI | $1972-2002$ | SSB |
|  |  |  |  |

## D. Short-Term Projection

The short-term prediction method was substantially modified in 2002. Following the review by SGEHAP (ICES 2001/ACFM:22), which recommended that a simple multi-fleet method would be preferable, the complex split-factor method used for a number of years prior to 2002 has not been used since. The multi-fleet, multi-option, deterministic short-term prediction programme (MFSP) was accepted by ACFM and was developed further last year. It is intended to continue to use this programme in the future. The good agreement between predicted biomass for the actual year and SSB taken from the assessment for the most recent year one year after demonstrates that the current prediction procedure for stock numbers is working well. In 2004, the Working Group has included prediction of low maturation into projections for 2005 and expects to monitor growth and maturation of North Sea herring carefully in the future and when deemed necessary will include these changes in predictions in the future.

Model used: Age-structured model, by fleet and area fished

Software used: MFSP

Initial stock size: output from ICA

Maturity: average of the two most recent years used

F and M before spawning: 0.67 for both (assumes spawning starts around September)

Weight at age in the stock: from last year in assessment (already smoothed, see assessment data description)

Weight at age in the catch: average of last two years BY FLEET

## Exploitation pattern:

Intermediate year assumptions: Status quo $F$

Stock recruitment model used: Recent average recruitment (arithmetic, recent 10 years) is used, (unless there is some strong reason for using something else, e.g. if SSB is very low, we may use a prediction from the stock-recruit relationship)

Procedures used for splitting projected catches:
There are 4 values input for this parameter:
(a) IBTS 1-ringer proportion in last assessment year (y) is used for 1-ringers in y
(b) IBTS 1-ringer proportion in $\mathrm{y}+1$ is used for 1 -ringers in $\mathrm{y}+1$, AND for 0 -ringers in y .
(c) GLM (between MIK index and IBTS 1-ringer proportion) is applied to MIK index in $\mathrm{y}+1$ to predict proportion for 1-ringers in $\mathrm{y}+2$, AND for 0 -ringers in $\mathrm{y}+1$
GLM, as in (c), is applied to the Average MIK index for 1981 to year y to predict proportion for 1-ringers in $\mathrm{y}+3$ (not relevant), AND for 0 -ringers in $\mathrm{y}+2$ (relevant)

## E. Medium-Term Projections - still to be filled in -

## G. Biological Reference Points

There is a well functioning harvest control rule in place for this stock, and apart from $\mathrm{B}_{\mathrm{lim}}$, the current reference points are derived from this HCR. The target F in the HCR was adopted by ACFM as the $\mathrm{F}_{\mathrm{pa}}$, while the trigger point at which $F$ should be reduced below the target is adopted as $B_{p a}$. The HCR was briefly revisited in 2004, and the results support the initial definitions of limits.

Reference points currently in use are: $\mathrm{B}_{\text {lim }}$ is 800000 t (below this value poor recruitment has been experienced); $\mathrm{B}_{\mathrm{pa}}$ be set at 1.3 mill. T (as part of a harvest control rule based on simulations); $\mathrm{F}_{\text {lim }}$ is not defined, $\mathrm{F}_{\mathrm{pa}}$ be set at $\mathrm{F}_{\text {ages } 0-1}=0.12$, $F_{\text {ages 2-6 }}=0.25$ (as part of a harvest control rule).

## H. Other Issues

## H. 1 Biology of the species in the distribution area

The herring (Clupea harengus) is a pelagic species which is widespread in its distribution throughout the North Sea. The herring's unique habit is that it produces benthic eggs which are attached to a gravely substrate on the seabed. This points strongly to an evolutionary history in which herring spawned in rivers and at some later date re-adapted to the marine environment. The spawning grounds in the southern North Sea are in fact located in the beds of rivers which existed in geological times and some groups of spring spawning herring still spawn in very shallow inshore waters and estuaries. Spawning typically occurs on coarse gravel $(0.5-5 \mathrm{~cm})$ to stone $(8-15 \mathrm{~cm})$ substrates and often on the crest of a ridge rather than hollows. For example, in a spawning area in the English Channel, eggs were found attached to flints $2.5-25 \mathrm{~cm}$ in length, where these occurred in gravel, over a 3.5 km by 400 m wide strip.

As a consequence of the requirement for a very specific substrate, spawning occurs in small discrete areas in the near coastal waters of the western North Sea. They extend from the Shetland Isles in the north through into the English Channel in the south. Within these specific areas actual patches of spawn can be extremely difficult to find.

The fecundity of herring is length related and varies between approximately 10,000 and 60,000 eggs per female. This is a relatively low fecundity for teleosts, probably because, in evolutionary terms, the benthic egg is a potentially less hazardous phase of development compared with the planktonic egg of most other teleosts. The age of first maturity is 3 years old ( 2 ringers) but the proportion mature at age may vary from year to year dependent on feeding conditions. Over the past 15 years the proportion mature at age 3 years ( 2 ringers) has ranged from $47 \%$ to $86 \%$ and for 4 year old fish ( 3 winter ringers) from $63 \%$ to $100 \%$. Above that age, all are considered to be mature.

The benthic eggs take about three weeks to hatch dependant on the temperature. The larvae on hatching are 6 mm to 9 mm long and are immediately planktonic. Their yolk sac lasts for a few days during which time they will begin to feed on phytoplankton and small planktonic animals. Their planktonic development lasts around three to four months during
which time they are passively subjected to the residual drift which takes them to various coastal nursery areas on both sides of the North Sea and into the Skagerrak and Kattegat.

Herring continue to be mainly planktonic feeders throughout their life history although there are numerous records of them taking small fish, such as sprat and sandeels, on an opportunistic basis. Calanoid copepods, such as Calanus, Pseudocalanus and Temora and the Euphausids, Meganyctiphanes and Thysanoessa still form the major part of their diet during the spring and summer and are responsible for the very high fat content of the fish at this time.

In the past, herring age has been determined by using the annual rings on the scales. In more recent years the growth rings on the otolith have proved more reliable for age determination. Herring age is expressed as number of winter rings on the otolith rather than age in years as for most other teleost species where a nominal 1 January birthdate is applied. Autumn spawning herring do not lay down a winter ring during their first winter and therefore remain as ' 0 ' winter ringers until the following winter. When looking at year classes, or year of hatching, it must be remembered that they were spawned in the year prior to their classification as ' 0 ' winter ringers.

North Sea herring comprise both spring and autumn spawning groups but the major fisheries are carried out on the offshore autumn spawning fish. The spring spawners are found mainly as small discrete coastal groups in areas such as The Wash and the Thames estuary. Juveniles of the spring spawning stocks found in the Baltic, Skagerrak and Kattegat may also be found in the North Sea as well as Norwegian coastal spring spawners.

The main autumn spawning begins in the northern North Sea in August and progresses steadily southwards through September and October in the central North Sea to November and as late as January in the southern North Sea and eastern English Channel. The widespread but discrete location of the herring spawning grounds throughout the western North Sea has been well known and described since the early part of the 20 th Century. This led to considerable scientific debate and eventually to investigation and research on stock identity. The controversy centred on whether or not the separate spawning grounds represented discrete stocks or 'races' within the North Sea autumn spawning herring complex. Resolution of this issue became more urgent as the need for the introduction of management measures increased during the 1950's. The International Council for the Exploration of the Sea (ICES) encouraged tagging and other racial studies and a review of all the historic evidence to resolve this problem. The conclusions were the basis for establishing the working hypothesis that the North Sea autumn spawning herring comprise a complex of three separate stocks each with separate spawning grounds, migration routes and nursery areas, illustrated in the figure below.

The three stock units are:

- The Buchan or Scottish group which spawn from July to early September in the Orkney Shetland area and off the Scottish east coast. Nursery areas for fish up to two years old are found along the east coast of Scotland and also across the North Sea and into the Skagerrak and Kattegat.
- The Banks or central North Sea group, which derive their name from their former spawning grounds around the western edge of the Dogger Bank. These spawning grounds have now all but disappeared and spawning is confined to small areas along the English east coast, from the Farne Islands to the Dowsing area, from August to October. The juveniles are found along the east coast of England, down to the Wash, and also off the west coast of Denmark.
- The Downs group which spawns in very late Autumn through to February in the southern Bight of the North Sea and in the eastern English Channel. The drift of their larvae takes them north-eastwards to nursery areas along the Dutch coast and into the German Bight (Burd 1985).

At certain times of the year, individuals from the three stock units may mix and are caught together as juveniles and adults but they cannot be readily separated in the commercial catches. As a consequence, North Sea autumn spawning herring have to be managed as a single unit.

A further complication is that juveniles of the North Sea stocks are found, outside the North Sea, in the Skagerrak and Kattegat areas and are caught in various fisheries there. The proportions of juveniles of North Sea origin, found in these areas varies with the strength of the year class, with higher proportions in the Skagerrak and Kattegat when the year class is good.

## H. 2 Historic stock development and history of the fishery

Over many centuries the North Sea herring fishery has been a cause of international conflict sometimes resulting in war, but in more recent times in bitter political argument. There have also been fundamental changes in the nature of the
fisheries. These have been driven both by changes in catching power and in response to changes in market requirements, particularly the demand for fish meal and oil. Most of these changes have resulted in greater exploitation pressures that increasingly led to the urgent need to ensure a more rational exploitation of North Sea herring. Such pressures really began to exert themselves for the first time during the 1950's when the spawning stock biomass of North Sea autumn spawning herring fell from 5 million tonnes in 1947 to 1.4 million tonnes by 1957. That period also witnessed the decline and eventual disappearance of a traditional autumn drift net fishery in the southern North Sea.

The annual landings from 1947 through to the early 1960's were high, but stable, averaging around 650,000 t. Over the period 1952-62 the high fishing mortality (F 0.4 ages 2-6) resulted in a rapid decline in the spawning stock biomass from around 5 million tonnes to 1.5 million tonnes. Recruitment over this period was reasonable, but there were fewer and fewer year classes present in the adult stock, a clear indication that the stocks were being over-fished and that they were also being impacted by the developing industrial fishery in the eastern North Sea.

This period witnessed the complete collapse of the historic East Anglian autumn drift net fishery, which was based entirely on the Downs stock moving south to the Southern Bight and eastern English Channel to spawn. The reasons for that failure have been attributed both to high mortality of the juveniles in the North Sea industrial fisheries, and to heavy fishing by bottom trawlers on the spawning concentrations, in the English Channel, during the 1950's. Such intensive trawling, on vulnerable spawning fish, not only generated a high mortality but also disturbed spawning aggregations, destroyed the spawn and damaged the substrate on which successful spawning depends.

Fishing mortality on the herring in the central and northern North Sea began to increase rapidly in the late 1960's and had increased to F1.3 ages 2-6, or over 70\% per year of those age classes, by 1968. Landings peaked at over 1 million tonnes in 1965, around $80 \%$ of which were juvenile fish. This was followed by a very rapid decline in the SSB and the total landings. By 1975 the SSB had fallen to $83,500 \mathrm{t}$ although the total landings were still over 300,000 t. At the same time, spawning in the central North Sea had contracted to the grounds off the east coast of England whilst spawning grounds around the edge of the Dogger Bank were no longer used. This heralded the serious decline and near collapse of the North Sea autumn spawning herring stock which led to the moratorium on directed herring fishing in the North Sea from 1977 to 1981.

International larvae surveys and acoustic surveys were used to monitor the state of the stocks during the moratorium. By 1980 these surveys were indicating a modest recovery in the SSB from its 1977 low point of 52,000 t. By 1981 the SSB had increased to over 200,000t. Prior to the moratorium there had been no control, other than market forces, on catches in the North Sea directed herring fishery. Once the fishery re-opened in 1981 the North Sea autumn spawning herring stock was managed by a Total Allowable Catch (TAC) constraint. It should be noted that the TAC was only applied to the directed herring fishery in the North Sea which exploited mainly adult fish for human consumption. Targeted fishing for herring for industrial purposes was banned in the North Sea in 1976 but there was a $10 \%$ by-catch allowance in the fisheries for other species, including the small meshed fisheries for industrial purposes, mainly for sprat. Following the re-opening of the now controlled fishery the SSB steadily increased, peaking at 1.3 million tonnes in 1989. Annual recruitment, measured as ' 0 'group fish, was well above the longterm average over this period. The 1985 year class was the biggest recorded since 1960 and the third highest in the records dating back to 1946. Landings also steadily increased over this period reaching a peak of 876,000 tonnes in 1988. This resulted from a steady increase in fishing mortality to $\mathrm{F}_{\text {ages } 2-6}=0.6$ (ca. $45 \%$ ) in 1985 and a high by-catch of juveniles in the industrial fisheries for sprat. Following a period of four years of below average recruitment (year classes 1987-91) SSB fell rapidly to below 500,000 tonnes in 1993. Fishing mortality increased rapidly averaging $\mathrm{F}_{\text {ages } 2-6}=0.75$ (ca. $52 \%$ ) over the period 1992-95 and recorded landings regularly exceeded the TAC. The North Sea industrial fishery for sprat developed rapidly over this period with the annual catch increasing from 33,000 tonnes in 1987 to 357,000 tonnes by 1995 . With the $10 \%$ by-catch limit as the only control on the catch of immature herring, there was a consequent high mortality on juvenile herring which averaged $76 \%$ of the total catch in numbers of North Sea autumn spawners over this period.

During the summer of 1991 the presence of the parasitic fungus Ichthyophonus spp was noted in the North Sea herring stock. All the evidence suggested that the parasite was lethal to herring and that its occurrence could have a significant effect on natural mortality in the stock and ultimately on spawning stock biomass. High levels of infection were recorded in the northern North Sea north of latitude $60^{\circ} \mathrm{N}$ whilst infection rates in the southern North Sea and English Channel were very low. Efforts were made to estimate the prevalence of the disease in the stock through a programme of research vessel and commercial catch sampling. This led to estimates of annual mortality up to $16 \%$ (Anon., 1993) which was of the same order as the estimate of fishing mortality at the time. It was recognised that the behavioural changes and catchability of infected fish affected the reliability of the estimate of prevalence of the disease in the population. The uncertainty about the effect on stock size varied between estimates of $5 \%$ to $10 \%$ and $20 \%$. Continued monitoring of the progress of the disease showed that by 1994 the prevalence in the northern North Sea had fallen from $5 \%$ in 1992 to below $1 \%$ and confirmed that the infection did not appear to be spreading to younger fish. Ultimately it was concluded that the disease had caused high mortality in the northern North Sea during 1991 and subsequently declined to the point where by 1995 the disease induced increase in natural mortality was insignificant.

The increased fishing pressure during the first half of the 1990 's and the disease induced increase in natural mortality led to serious concerns about the possibilities of a stock collapse similar to that in the late 1970's. Reported landings continued at around 650,000 tonnes per year whilst the spawning stock began to decline again from over 1 million tonnes in 1990. The assessments at that time were providing an over optimistic perception of the size of the spawning stock and, for example, it was not until 1995 that it was realised that the SSB in 1993 had already fallen below 500,000 tonnes. This was well below the minimum biologically accepted level of 800,000 tonnes (MBAL) which had been set for this stock at that time.

## H. 3 Management and ACFM advice

In 1996, the total allowable catches (TACs) for Herring caught in the North Sea (ICES areas IV and Division VIId) were changed mid-year with the intention of reducing the fishing mortality by $50 \%$ for the adult part of the stock and by $75 \%$ for the juveniles. For 1997, the regulations were altered again to reduce the fishing mortality on the adult stock to 0.25 and for juveniles to less than 0.1 with the aim of rebuilding the SSB up to 1.1 million t in 1998.

According to the EU and Norway agreement adopted in December 1997, efforts should be made to maintain the SSB above the MBAL (Minimum Biologically Acceptable Level) of 800,000 tonnes. An SSB reference point of 1.3 million has been set above which the TACs will be based on an $\mathrm{F}=0.25$ for adult herring and $\mathrm{F}=0.12$ for juveniles. If the SSB falls below 1.3 million tonnes, other measures will be agreed and implemented taking account of scientific advice. Relevant parts of the agreement (last amended Dec. 2001) read:

1. Every effort shall be made to maintain a level of Spawning Stock Biomass (SSB) greater than the Minimum Biological Acceptable Level (MBAL) of 800,000 tonnes.
2. A medium-term management strategy, by which annual quotas shall be set for the directed fishery and for bycatches in other fisheries as defined by ICES, reflecting a fishing mortality rate of 0.25 for 2-ringers and older and 0.12 for 0-1-ringers, shall be implemented.
3. Should the SSB fall below a reference point of 1.3 million tonnes, the fishing mortality rates referred under paragraph 2, will be adapted in the light of scientific estimates of the precise conditions then prevailing, to ensure rapid recovery of SSB to levels in excess of 1.3 million tonnes.

The recovery plan referred to above may, inter alia, include additional limitations on effort in the form of special licensing of vessels, restrictions on fishing days, closing of areas and/or seasons, special reporting requirements or other appropriate control measures.
4. By-catches of herring may only be landed in ports where adequate sampling schemes to effectively monitor the landings have been set up. All catches landed shall be deducted from the respective quotas set, and the fisheries shall be stopped immediately in the event that the quotas are exhausted.
5. The allocation of the TAC for the directed fishery for herring shall be $29 \%$ to Norway and $71 \%$ to the Community. The by-catch quota for herring shall be allocated to the Community.
6. The parties shall, if appropriate, consult and adjust management measures and strategies on the basis of any new advice provided by ICES including that from the assessment of the abundance of the most recent year class.
7. A review of this arrangement shall take place no later than 31 December 2004.
8. This arrangement entered into force on 1 January 2002.

Until 2002, the SSB has been below the precautionary level of 1.3 million tonnes ( $\mathbf{B}_{\mathrm{pa}}$ ), and since 1998 other measures taken have consisted of an adoption of a $\mathrm{F}_{2-6}$ of 0.2 and a $\mathrm{F}_{0-1}<0.1$ to allow the rebuilding of the spawning biomass to above $\mathbf{B}_{\mathrm{pa}}$.

Since 2002, the SSB is considered to have been above $\mathbf{B}_{\mathrm{pa}}$. From then on, ACFM gave fleetwise catch option tables for fishing mortalities within the constraints the EU-Norway management scheme.

## H. 4 Sampling of commercial catch

Sampling of commercial catch is conducted by the national institutes. HAWG has recommended for years that sampling of commercial catches should be improved for most of the stocks. In January 2002, a new directive for the collection of fisheries data was implemented for all EU member states (Commission Regulation 1639/2001). The provisions in the "data directive" define specific sampling levels. As most of the nations participating in the fisheries on herring assessed here have to obey this data directive, the definitions applicable for herring and the area covered by HAWG are given below:

| Area | sampling level per 1000 t catch |  |  |
| :--- | :--- | :--- | :--- |
| Baltic area (IIIa (S) and IIIb-c) | 1 sample of which | 100 fish measured and | 50 aged |
| Skagerrak (IIIa (N)) | 1 sample | 100 fish measured | 100 aged |
| North Sea (IV and VId): | 1 sample | 50 fish measured | 25 aged |
| NE Atlantic and Western Channel ICES areas II, 1 sample | 50 fish measured | 25 aged |  |
| V, VI, VII (excluding d) VIII, IX, X, XII, XIV |  |  |  |

Exemptions to the above mentioned sampling rules are:

## Concerning lengths:

(1) the national programme of a Member State can exclude the estimation of the length distribution of the landings for stocks for which TACs and quotas have been defined under the following conditions:
(i) the relevant quotas must correspond to less than $5 \%$ of the Community share of the TAC or
to less than 100 tonnes on average during the previous three years;
(ii) the sum of all quotas of Member States whose allocation is less than $5 \%$, must account for
less than $15 \%$ of the Community share of the TAC.
If the condition set out in point (i) is fulfilled, but not the condition set out in point (ii), the relevant Member States may set up a coordinated programme to achieve for their overall landings the implementation of the sampling scheme described above, or another sampling scheme, leading to the same precision.

## Concerning ages:

(1) the national programme of a Member State can exclude the estimation of the age distribution of the landings for stocks for which TACs and quotas have been defined under the following conditions:
(i) the relevant quotas correspond to less than $10 \%$ of the Community share of the TAC or to
less than 200 tonnes on average during the previous three years;
(ii) the sum of all quotas of Member States whose allocation is less than $10 \%$, accounts for less than $25 \%$ of the Community share of the TAC.
If the condition set out in point (i) is fulfilled, but not the condition set out in point (ii), the relevant Member States may set up a coordinated programme as mentioned for length sampling.

If appropriate, the national programme may be adjusted until 31 January of every year to take into account the exchange of quotas between Member States;

The HAWG reviewed the implementation of the new sampling regime for the EU countries in 2003. It was expected that the overall sampling level might be improved, and this was demonstrated e.g. for North Sea herring in 2002 and 2003. However, there is concern that the new regime may lead to a deterioration of sampling quality, because it does not assure an appropriate sampling of different métiers (each combination of fleet/nation/area and quarter). Given the diversity of the fleets harvesting most stocks assessed by HAWG, an appropriate spread of sampling effort over the different métiers is more important to the quality of catch at age data than a sufficient overall sampling level. The EU data directive appears to not assure this. The WG therefore recommends that all metiers with substantial catch should be sampled (including by-catches in the industrial fisheries), that catches landed abroad should be sampled and information on these samples should be made available to the national laboratories.

## H. 5 Terminology

The WG uses "rings" rather than "age" or "winter rings" throughout the report to denominate the age of herring, with the intention to avoid confusion It should be observed that, for autumn spawning stocks, there is a difference of one year between "age" and "rings". HAWG in 1992 (ICES 1992/Assess:11) stated that
"The convention of defining herring age rings instead of years was introduced in various ICES working groups around 1970. The main argument to do so was the uncertainty about the racial identity of the herring in some areas. A herring with one winter ring is classified as 2-years-old if it is an autumn spawner, and one-year-old if it is a spring spawner. Recording the age of the herring in rings instead of in years allowed scientists to postpone the decision on year of birth until a later date when they might have obtained more information on the racial identity of the herring.

The use of winter rings in ICES working groups has introduced a certain amount of confusion and errors. In specifying the age of the herring, people always have to state explicitly whether they are talking about rings or years, and whether the herring are autumn- or spring spawners. These details tend to get lost in working group reports, which can make these reports confusing for outsiders, and even for herring experts themselves. As the age of all other fish species (and of herring in other parts of the world) is expressed in years, one could question the justification of treating WestEuropean herring in a special way. Especially with the present trend towards multispecies assessment and integration of ICES working groups, there might be a case for a uniform system of age definition throughout all ICES working groups.

However, the change from rings to years would create a number of practical problems. Data files in national laboratories and at ICES would have to be adapted, which would involve extra costs and manpower. People that had not been aware of the change might be confused when comparing new data with data from old working group reports. Finally, in some areas (notably Division IIIa), the distinction between spring- and autumn spawners is still hard to make, and scientists preferred to continue using rings instead of years.

The Working Group discussed at length the various consequences of a change from rings to years. The majority of the Group felt that the advantages of such a change did not outweigh the disadvantages, and it was decided to stick to the present system for the time being."

The text table below gives an example for the correlation between age, rings and year class for the different spawning types in late 2002:

| Year class (autumn spawners) | 2001/2002 | 2000/2001 | 1999/2000 | $1998 / \mathbf{1 9 9 9}$ |
| :--- | ---: | ---: | ---: | ---: |
| Rings | $\mathbf{0}$ | $\mathbf{1}$ | $\mathbf{2}$ | $\mathbf{3}$ |
| Age (autumn spawners) | 1 | 2 | 3 | 4 |
| Year class (spring spawners) | $\mathbf{2 0 0 2}$ | $\mathbf{2 0 0 1}$ | $\mathbf{2 0 0 0}$ | $\mathbf{1 9 9 9}$ |
| Rings | $\mathbf{0}$ | $\mathbf{1}$ | $\mathbf{2}$ | $\mathbf{3}$ |
| Age (spring spawners) | 0 | 1 | 2 | 3 |

Stock Western Baltic Spring spawning herring (WBSS)<br>Working Group: Herring Assessment Working Group for the Area South of $62^{\circ} \mathrm{N}$<br>Date: 18.03.2004

Authors:

M. Cardinale, J. Dalskov, T. Gröhsler, H. Mosegaard,A. General

## A.1. Stock definition

Herring caught in Division IIIa are a mixture of North Sea autumn spawners and Baltic spring spawners. Springspawning herring in the eastern part of the North Sea, Skagerrak, Kattegat and SDs 22, 23 and 24 are considered to be one stock.

Catches of herring in the Kattegat, the Skagerrak and the Eastern part of the North Sea are taken from a mixture of two main spawning stocks (ICES, 1991/Assess:15): mainly 2+ ringers of the Western Baltic spring-spawners and 0-2ringers from the North Sea autumn-spawners, including winter-spawning Downs herring. In addition, several local spawning stocks have been identified with a minor importance for the herring fisheries (ICES, 2001/ACFM 12).

The method of separating herring in Norwegian samples, using vertebral counts as described in former reports of this Working Group (ICES 1991/ Assess:15) assumes that for autumn spawners, the mean vertebral count is 56.5 and for Spring spawners 55.80. The fractions of spring spawners (fsp) are estimated from the formula (56.50-v)/(56.5-55.8), where v is the mean vertebral count of the (mixed) sample with the restriction that the proportion should be one if $\mathrm{fsp}>=1$ and zero if $\mathrm{fsp}<=0$. The method is quite sensitive to within-stock variation (e.g. between year classes) in mean vertebral counts.

Experience within the Herring Assessment Working Group has shown that separation procedures based on size distributions often will fail. The introduction of otolith microstructure analysis in 1996-97 (Mosegaard and PoppMadsen, 1996) enables an accurate and precise split between three groups, autumn, winter and spring-spawners; however, different populations with similar spawning periods are not resolved with the present level of analysis. Different stock components that are not easily distinguished by their otolith microstructure (OM), are considered to have different mean vertebral counts (vs) as, e.g., winter-spawning Downs herring: 56.6 (Hulme, 1995), and the small local stocks, the Skagerrak winter/spring-spawners: 57 (Rosenberg and Palmén, 1982). Further, the estimated stock specific mean vs count varies somewhat among different studies; North Sea: 56.5, Western Baltic Sea: 55.6 (Gröger and Gröhsler, 2001) and North Sea: 56.5, Western Baltic Sea: 55.8 (ICES 1992/H:5). Comparison between separation methods using frequency distributions of vertebral counts and otolith microstructure showed reasonable correspondence. Using this information the years from 1991 to 1996 was reworked in 2001, applying common splitting keys for all years by using a combination of the vertebral count and otolith microstructure methods (ICES, 2001/ACFM:12). From 2001 and onwards, the otolith-based method only has been used for the Div. IIIa.

Different methods of identifying herring stocks in the Division IIIa and Subdivisions 22-24 were recently evaluated in a EU CFP study project (EC study 98/026). The study involved several inter-calibration sessions between microstructure readers in the different laboratories involved with the WBSS herring. After the study was finished a close collaboration concerning reader interpretations has been kept between the Danish and Swedish laboratories. Sub-samples of the 2002 and 2003 Danish, Swedish, and German microstructure analyses were double-checked by the same Danish expert reader for consistency in interpretation. The overall impression is an increasingly good agreement among readers.

New molecular genetic approaches for stock separation are being developed within the EU-FP5 project HERGEN (EU project QLRT 200-01370). Sampling of spawning aggregations during spring, autumn and winter has been carried out in 2002 and in 2003 in Div. IIIa and in the Western Baltic at more than 10 different locations. Preliminary results point at a substantial genetic variation between North Sea and Western Baltic herring, but significant variation has also been found among spawning populations in DivIIIa and subdiv. 22-24.

For Subdivisions 22, 23 and 24 it is assumed that all individuals caught belong to the Western Baltic spring spawning stock.

After the introduction of otolith microstructure analysis in 1996 it was discovered that in the western Baltic a small percentage of the herring landings might consist of autumn-spawners individuals. Before molecular genetic methods became available for Atlantic herring the existence of varying proportions of autumn spawners in Subdivisions 22-24 in different years was considered a potential problem for the assessment.

Although local aggregations of winter and autumn spawning herring are found in the Western Baltic area these aggregations are genetically more closely related to the Western Baltic spring spawners than to the North Sea autumn spawners (HERGEN, EU project QLRT 200-01370). Therefore, with the present genetic perception in mind, when herring with otolith microstructure indicating autumn hatch are found in subdivisions 22-24 these are treated as belonging to the WBSS stock.

## A.2. Fishery

The fleet definitions used since 1998 for the fishery in Div. IIIa are:

- Fleet C: directed fishery for herring in which trawlers (with 32 mm minimum mesh size) and purse seiners participate.
- Fleet D: All fisheries in which trawlers (with mesh sizes less than 32 mm ) and small purse seiners, fishing for sprat along the Swedish coast and in the Swedish fjords, participate. For most of the landings taken by this fleet, herring is landed as by-catch.

Danish and Swedish by-catches of herring from the sprat fishery and the Norway pout and blue-whiting fisheries are listed under fleet D.

In SDs 22-24 most of the catches are taken in a directed fishery for herring and some as by-catch in a directed sprat fishery. All landings from SDs22-24 are treated as one fleet.

## A.3. Ecosystem aspects

Applying new molecular genetic methods and results emerging from ongoing research projects on herring (HERGEN and WESTHER) the possibility of considering genetic diversity is within reach. Preliminary results indicate an increase in genetic distance between herring populations in the Baltic and successive populations in subdivisions 24, 22, 21, and 20 and finally the North Sea where genetic distance reach a maximum constant difference to the Baltic. Further, genetic differences are larger among populations within the DivIIIa and Western Baltic than among populations in the North Sea.

## B. Data

## B.1. Commercial catch

The level of sampling of the landings for the human consumption fishery and the small-meshed fishery landings was generally acceptable in the Skagerrak, the Kattegat and SDs 22-24 during the last years. Where sampling was missing in areas and quarters on national landings, sampling from either other nations or adjacent areas and quarters were used to estimate catch in numbers and mean weight-at-age.

Based on the proportions of spring- and autumn spawners in the landings, number and mean weights by age and spawning stock are calculated.

The text table below the shows different input data provided by country:

|  | Data |  |  |
| :--- | :--- | :--- | :--- |
| Country | Caton <br> (catch in weight) | Canum <br> (catch-at-age <br> numbers) | Weca <br> (weight-at-age in the catch) |
| Denmark | x | x | x |
| Germany | x | x | x |
| Norway | x |  |  |
| Poland | x | x | x |
| Sweden | x | x | x |

## B.2. Biological

Mean weights-at-age in the catch in the $1^{\text {st }}$ quarter were used as stock weights.
The proportions of F and M before spawning was assumed constant between years. F-prop was set to be 0.1 and M-prop 0.25 for all age groups.

Natural mortality was assumed constant at 0.2 for all years and $2+$ ringers. A predation mortality of 0.1 and 0.2 was added to the 0 and 1 ringers, which resulted in an increase in their natural mortality to 0.3 and 0.5 , respectively (Table 3.6.4). The estimates of predation mortality were derived as a mean for the years 1977-1995 from the Baltic MSVPA (ICES 1997/J:2).

The maturity ogive was assumed constant between years:

| W-rings | 0 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | $8+$ |
| :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- |
| Maturity | 0.00 | 0.00 | 0.20 | 0.75 | 0.90 | 1.00 | 1.00 | 1.00 | 1.00 |

## B.3. Surveys

The summer Danish acoustic survey in Division IIIa is part of an annual survey covering the North Sea and Division IIIa in July-August. R/V DANA conducted the survey in Division IIIa. For each sub area the mean back scattering cross section was estimated for herring, sprat, gadoids and mackerel by the TS relationships given in the Manual for Herring Acoustic Surveys in ICES Division III, IV, and IVa (ICES 2002/G:02). Used in the final assessment.

The first joint acoustic survey was carried out with R/V 'Solea' in Subdivisions 22-24 in October 1987. Since 1989 the survey was repeated every year as a part of an international hydracoustic survey in the Baltic. Used in the final assessment.

The IBTS $3^{\text {rd }}$ quarter survey in Div. IIIa, which is a part of the North Sea and Div. IIIa bottom trawl survey that is carried out in the $1^{\text {st }}$ and $3^{\text {rd }}$ quarter. The IBTS has been conducted annually in the $1^{\text {st }}$ quarter since 1977 and $3^{\text {rd }}$ quarters from 1991. From 1983 and onwards the survey was standardised according to the IBTS manual (ICES 2002/D:03). During the HAWG 2002 the IBTS survey data (both quarter) were revised from 1991 to 2002. Historical catch rates are heavily skewed and therefore the survey indices by winter rings $1-5$ were calculated as geometric means from observed abundances $\left(\mathrm{n} \cdot \mathrm{h}^{-1}\right)$ at age at trawl stations. Used in the final assessment.

The German herring larvae monitoring started in 1977 and takes place every year from March/April to June in the main spawning grounds of the spring spawning herring in the Western Baltic. These are the Greifswalder Bodden and adjacent waters. For the calculation of the number of larvae per station and area unit, the methods of Smith and Richardson (1977) and Klenz (1993) were used and projected to length-classes. Further details concerning the surveys and the treatment of the samples are given in Brielmann (1989), Müller and Klenz (1994) and Klenz (2002). Used in the final assessment.

## D. Short-Term Projection

Model used: Age structured
Software used: MFDP Vs 1a
Initial stock size: ICA estimates of population numbers were used except for

- the numbers of 0 -ringers in the last two years and the start year of the projection, where a geometric mean of the recruitment over the period of ten years was taken
- the numbers of 1-ringers in the start of the projection, where the geometric mean over the period of ten years excluding the last year was used

Maturity: The same values as in the assessment is used for all years
$F$ and $M$ before spawning: The same ogive as in the assessment is used for all years

Weight-at-age in the stock: Average weight of the three last years

Weight-at-age in the catch: Average weight of the three last years
Exploitation pattern: Average weight of the three last years
Intermediate year assumptions: Status quo fishing mortality
Stock recruitment model used: None
Procedures used for splitting projected catches: Not relevant

# Appendix 4 - Stock Annex 

## Quality Handbook

## ANNEX: Herring in Celtic Sea and VIIj

Stock specific documentation of standard assessment procedures used by ICES.
Stock Herring in the Celtic Sea and VIIj
Working Group: Herring Assessment Working Group for the area south of $62^{0} \mathrm{~N}$.
Date: $\quad 19^{\text {th }}$ April 2004

## A. General

## A.1. Stock definition

The herring to the south of Ireland in the Celtic Sea and in Division VIIj comprise both autumn and winter spawning components. For the purpose of stock assessment and management, these areas have been combined since 1982. Spawning in VIIj has traditionally taken place in the autumn and in VIIg and VIIaS, later in the autumn and in the winter.

## A.2. Fishery

In recent years, this fishery has been prosecuted entirely by Ireland. The fishing season is the same as the assessment period, $1^{\text {st }}$ April to the $31^{\text {st }}$ March the following year. The TAC is set on an annual basis, however.

In the past season season, the fishery was allowed to remain open throughout. This was to allow vessels to target fish outside the spawning seasons when the fish are of better quality and marketability. The spawning grounds are protected by rotating box closures implemented under EU legislation. In addition to these, one box was voluntarily closed in the recent seasons. This initiative was initiated by the Irish Southwest Pelagic Management Committee to afford extra protection to first time spawners. The Irish Southwest Pelagic Management Committee was established to manage the Irish fishery for this herring stock. This committee, therefore, has responsibility for management of the entire fishery for this stock at present.

Landings have decreased markedly in recent years from around 20,000 $t$ in the 1997/1998 season to around $11,000 \mathrm{t}$ in the $2003 / 2004$ season. The fishery is currently prosecuted by Irish RSW pelagic trawlers and by Irish polyvalent trawlers using pelagic gear.

## A.3. Ecosystem aspects

## B. Data

## B.1. Commercial catch

The commercial catches are provided by national laboratories belonging toe the nations that have quota for this stock. In recent years, only Ireland has caught herring in this area, so catch-at-age, mean weights and stock weights are derived entirely from Irish sampling. Sampling is performed as part of commitments under the EU Council Regulation 1639/2001.

Commercial catch at age data are submitted in Exchange sheet v 1.6.4. These data are usually processed using SALLOCL. This program (Patterson, 1998). This program gives outputs on sampling status and available biological parameters and documents actions taken to raise unsampled metiers using other data sets. The species co-ordinator allocates samples of catch numbers, mean length and mean weight-at-age to unsampled catches using appropriate
samples by gear (fleet) area quarter and if an exact match is not available then a neighbouring area if the fishery extends to this area in the same quarter.

## B.2. Biological

Mean weights at age in the catch in the $4^{\text {th }}$ and $1^{\text {st }}$ quarter are used as stock weights. This is a new procedure first used in 2004, because much of the catch was taken in the summer, before the spawning period.

The natural mortality is based on the results of the MSVPA for North Sea herring.

## B.3. Surveys

A series of acoustic surveys have been carried out on this stock from 1990-1996. The series was interrupted in 1997 due to the lack of the survey vessel, it was resumed in 1998. For the $2002 / 2003$ season one acoustic survey was carried out to determine stock abundance. It was decided that a single survey carried out on fish approaching the grounds would be sufficient to contain the stock. A review of this survey series is in preparation (O'Donnell et al. in prep.).

## B.4. Commercial CPUE

Not used for this stock.

## B.5. Other relevant data

## C. Historical Stock Development

Model used:
Recent WG's have used the results of the acoustic surveys in the ICA programme but stated that the results should be taken as minimum estimates.

Software used: The ICA package is used.
Model Options chosen:
The period of separable constraint is 6 years, with areference age of 3 -ring. Terminal selection is fixed at 1.0 . Reference F is calculated for 2-ring to 7 -ring fish. Fish of 1-ring are down weighted by 0.1 , all other ages are not down weighted.

The acoustic abundance estimates are included for ages 2-5 only (winter rings). The acoustic estimates are treated as a relative index, using a linear model.

Input data types and characteristics:

| Type | Name | Year range | Age range | Variable from year to <br> year <br> Yes/No |
| :--- | :--- | :--- | :--- | :--- |
| Caton | Catch in tonnes | $1958-2003$ | $1-9$ | Yes |
| Canum | Catch at age in numbers | $1958-2003$ | $1-9$ | Yes |
| Weca | Weight at age in the <br> commercial catch | $1958-2003$ | $1-9$ | Yes |
| West | Weight at age of the <br> spawning stock at <br> spawning time. | $1958-2003$ | $1-9$ | Yes |
| Mprop | Proportion of natural <br> mortality before spawning | $1958-2003$ | $1-9$ | No |
| Fprop | Proportion of fishing <br> mortality before spawning | $1958-2003$ | $1-9$ | No |
| Matprop | Proportion mature at age | $1958-2003$ | $1-9$ | No |
| Natmor | Natural mortality | $1958-2003$ | $1-9$ | No |

Tuning data:

| Type | Name | Year range | Age range |
| :--- | :--- | :--- | :--- |
| Tuning fleet 1 | CSHAS | $1990-2003$ | $2-5$ |
| Tuning fleet 2 |  |  |  |
| Tuning fleet 3 |  |  |  |
| $\ldots$. |  |  |  |

## D. Short-Term Projection

Model used: Multi fleet Deterministic Projection (Smith, 2000).

## Software used: MFDP Software

A short-term projection is carried out under the following assumptions. The number of 1 ringers was based on the geometric mean from 1958 to 2001. . This was followed to allow for the inclusion of the period of recruitment failure. This value was 406 million fish. Mean weights in the catch and in the stock were calculated as means over the period 1998-2003. Population numbers of 2-ringers in the 2004/2005 season was calculated by the degradation of geometric mean recruitment (1958-2001) using the equation, following the same procedure as last year.
$\mathrm{N}_{\mathrm{t}+1}=\mathrm{N}_{\mathrm{t}} * \mathrm{e}^{-\mathrm{F}+\mathrm{M}}$

Following the same procedure as last year, two scenarios are presented, one based on $\mathbf{F}_{\text {sq }}\left(=\mathrm{F}_{2003}\right)$, the other on a catch constraint of 13,000 (the TAC for 2004).

## E. Medium-Term Projections

## Not performed

## F. Long-Term Projections

Not performed

## G. Biological Reference Points

$\mathbf{B}_{\mathrm{pa}}$ is set at $44,000 \mathrm{t}$ and $\mathbf{B}_{\mathrm{lim}}$ at $26,000 \mathrm{t}$. F reference points are not defined for this stock.

## Quality Handbook

ANNEX: Her VIaN

Stock specific documentation of standard assessment procedures used by ICES.
Stock: Herring in VIa (North)
Working Group: Herring Assessment WG for the Area south of $62^{\circ} \mathrm{N}$
Date:
18 March 2004

Authors: E.M.C. Hatfield and E.J. Simmonds

## A. General

## A.1. Stock definition

The stock is distributed over ICES Division VIa (N). Some of the larger adults typically found close to the shelf break may be caught in division Vb .

## A.2. Fishery

The dominant fleet fishing in VIa (N) since 1957 has been the Scottish fleet. In the early years the Scottish fishery was prosecuted using a mixture of vessel size and gear, including gill nets, ring-nets and trawls. The boats were small, and targeted the coastal stock, primarily fishing in the winter. Until 1970 the only other nations fishing in this area on a regular basis were the former German Federal Republic, and to a much lesser extend the Netherlands. These fleets operated in deeper water near the shelf edge.

In 1970 a large increase in exploitation occurred with the entry of fleets from Norway and the Faroes, and an increased Netherlands catch. In addition, considerably smaller catches were taken by France and Iceland.

Throughout this period juvenile herring catches from the Moray Firth, in the north-east of Scotland, were included in the VIa catch figures, as tagging programs showed there to be some links between herring spawning to the west of Scotland and the Moray Firth juveniles.

Prior to 1982 herring stocks in ICES Area VIa were assessed as one stock, along with the herring by-catch from the sprat fishery in the Moray Firth. In the 1982 herring assessment working group report, and in subsequent years, Area VIa was split into a northern and a southern area at $56^{\circ} \mathrm{N}$ (ICES, 1982).

In 1979 and 1981 the fishery was closed. After re-opening the nature of the fishery changed to an extent, with fewer Scottish boats targeting the coastal stock than before the closure. The Scottish domestic pair trawl fleet and the Northern Irish fleet operated in shallower, coastal areas, principally fishing in the Minches and around the Island of Barra in the south; younger herring are found in these areas. Since 1986 Irish trawlers have operated in the south of the area, from the VIa (S) line up to the south-western Hebrides. The Scottish and Norwegian purse seine fleets targeted herring mostly in the northern North Sea, but also operated in the northern part of VIa (N). An international freezertrawler fishery operated in deeper water near the shelf edge where older fish are distributed. These vessels are mostly registered in the Netherlands, Germany, France and England. In recent years the catch of these fleets has become more similar and has been dominated by younger adults resulting from increased recruitment into the stock.

In recent years the Scottish fleet has changed to a predominantly purse-seine fleet to a trawl fleet. Norwegian vessels fish less in the area than in the past. Scottish catches still comprise around half of the total, the rest is dominated by the offshore, international fishery.

A recent EU-funded programme WESTHER aims to elucidate stock structures of herring throughout the western seaboard of the British Isles using a combination of morphometric measurements, otolith structure, genetics and parasite loads. The results of this should provide the best-available information on mixing of stocks within and beyond VIa (N).

## A.3. Ecosystem aspects

Herring in this area is an important food source for sea birds, sea mammals and many piscivorous fish.

Adult herring in VIa ( N ) can consume eggs of other fish species in the area. However, it has not been possible to demonstrate a relationship between herring abundance and recruitment to other stocks, and stomach investigations of herring do not indicate that the predation effect on eggs has significant impact on egg survival for other stocks.

## B. Data

## B.1. Commercial catch

Commercial catch is obtained from national laboratories of nations exploiting herring in VIa (N). Since 1999 (catch data 1998), these labs have used a spreadsheet to provide all necessary landing and sampling data, which was developed originally for the Mackerel Working Group (WGMHSA) and further adapted to the special needs of the Herring Assessment Working Group. The current version used for reporting the 2002 catch data was v1.6.4. The majority of commercial catch data of multinational fleets was provided on these spreadsheets and further processed with the SALLOCL-application (Patterson, 1998a). This program gives the needed standard outputs on sampling status and biological parameters. It also clearly documents any decisions made by the species co-ordinators for filling in missing data and raising the catch information of one nation/quarter/area with information from another data set.

Transparency of data handling by the Working Group. The current practice of data handling by the Working Group is that the data received by the co-ordinators is available in a folder called "archive". These high-resolution data are not reproduced in the report. The archived data contains the disaggregated dataset (disfad), the allocations of samples to unsampled catches (alloc), the aggregated dataset (sam.out) and (in some cases) a document describing any problems with the data in that year.

Current methods of compiling fisheries assessment data. The species co-ordinator is responsible for compiling the national data to produce the input data for the assessments. In addition to checking the major task involved is to allocate samples of catch numbers, mean length and mean weight-at-age to unsampled catches. There are at present no defined criteria on how this should be done, but the following general process is implemented by the species co-ordinators. Searches are made for appropriate samples by gear (fleet) area quarter, if an exact match is not available the search will move to a neighbouring area if the fishery extends to this area in the same quarter. More than one sample may be allocated to an unsampled catch, in this case a straight mean or weighted mean of the observations may be used. If there are no samples available the search will move to the closest non-adjacent area by gear (fleet) and quarter, but not in all cases.

Until 2003 the $\operatorname{VIa}(\mathrm{N})$ catch data extended back to the early 1970s; since 1986 the series has run from 1976 to present. In 2004 the data set was extended back to 1957. Details are given below.

## Historic Catches from 1957 to 1975

The working group has obtained preliminary estimates of catch and catch-at-age for the period 1957 to 1975. These have been estimated from records of catch presented in HAWG reports from 1973, 1974, 1981 and 1982. Intervening reports were also consulted to check for changes or updates during the period. Catch-at-age data were available from 1970 to 1975 from the 1982 Working Group report, and catches-at-age for the period 1957 to 1972 were estimated from paper records of catch-at-age by national fleets for 1957 to 1972, held at FRS Marine Laboratory Aberdeen. The fishing practices of national fleets were established for the period 1970 to 1980 from catches in VIa and VIa (N) recorded in the 1981 and 1982 Working Group reports respectively. This procedure suggested that, on average, more than $90 \%$ of catch by national fleet could be fully assigned to either VIa (N) or VIa (S). The remaining catch was assigned assuming historic proportions. During this period catches were split into autumn and spring spawning components; anecdotal information on trials to verify this separation suggests it was not a robust procedure. Currently about $5 \%$ of herring in VIa $(\mathrm{N})$ is found to be spent at the time of the acoustic surveys in July, and thought to be spring spawning herring. However, at present the Working Group assesses VIa ( N ) herring as one stock, regardless of spawning stock affiliation. In the earlier period higher proportions were allocated as spring spawners. The Working Group considered that it was preferable to combine all catch in the earlier period as VIa (N) catch, as the spawning components are currently mixed and the historic separation was uncertain. Similarly, a small Moray Firth juvenile fishery was also included in VIa (N) catch in earlier years because it was thought that these juveniles were part of the

VIa (N) stock. Separating this component in the historic data was difficult, and as the fishery ceased in the very early 70 s this has no implications for current allocation of these fish. The Moray Firth is, geographically, part of IVa (ICES stat. rectangles 44E6, 44E7, 45E6) and is now managed as part of that area. Currently there are no juvenile herring catches from the Moray Firth. Full details of the analysis carried out is provided as an appendix (Appendix 11) to the 2004 Working Group report.

## Allocation of catch and misreporting

This fishery had a strong tradition of misreporting. It is believed that the shortfall between the TAC and the catch was used to misreport catches from other areas (from IVa to the east and from VIa (S) to the south). In the past, fisheryindependent information confirmed that large catches were being reported from areas with low abundances of fish, and informal information from the fishery and from other sources confirmed that most catches of fish recorded between $4^{\circ} \mathrm{W}$ and $5^{\circ} \mathrm{W}$ were most probably misreported North Sea catches. The problem was detailed in the Working Group report in 2002 (ICES 2002/ACFM:12). Improved information from the fishery in 1998-2002 allowed for re-allocation of many catches due to area misreporting (principally from VIa (N) to IVa (W)). This information was obtained from only some of the fleets

As a result of perceived problems of area misreporting of catch from IVa into VIa (N), Scotland introduced a new fishery regulation in 1997 aiming to improve reporting accuracy. Under this regulation, Scottish vessels fishing for herring are required to hold a license either to fish in the North Sea or in the west of Scotland area (VIa (N)). Only one of these options can be held at any one time.

The Working Group considers that the serious problems with misreporting of catches from this stock, with many examples of vessels operating and landing herring catches distant from VIa ( N ) but reporting catches from that area, have been reduced in recent years from some $30,000 \mathrm{t}$ in the mid 1990s to around $5,000 \mathrm{t}$ in 2002. In 2003, for the first time since 1983, observer data indicated there was no misreported catch..

Catches are included in the assessment. Biases and sampling designs are not documented. Discards are not included. Slippage and high grading are not recorded.

## B.2. Biological

Catch-at-age data (catch numbers-at-age, mean weights-at-age in the catch, mean length-at-age) are derived from the raised national figures received from the national laboratories. The data are obtained either by market sampling or by onboard observers, and processed as described in Section B. 1 above. For information on recent sampling levels and nations providing samples, see Section 2.2. in the most recent HAWG report.

Proportions mature (maturity ogive) and mean weights-at-age in the stock derived from the acoustic survey (see next section) have been used since 1992 and 1993, respectively. Prior to these years, time-invariant values derived from ??? were used.

Biological sampling of the catches was extremely poor in recent history (particularly in 1999). This was particularly the case for the freezer trawler fishery that takes the larger component of the stock based around the shelf break. The lack of samples was due in part to the fact that national vessels tend to land in foreign ports, avoiding national sampling programs. The same fleet is thought to high grade. The long length of fishing trips makes observer programs difficult. Even when samples are taken, age determination is limited for most nations.

Sampling has improved over the last few years. The number of age readings per $1,000 \mathrm{t}$ of catch increased from the low in 1999 of 52 to a high in 2001 of 93 . Numbers have decreased again since then to 57 per 1,000 t in 2003. From 1999 to 2003 the sampling has been dominated by Scotland (ranging between 70 and $98 \%$ of the age readings), except in 2001, when only $43 \%$ of the age determination was on Scottish landings in VIa (N).

Natural mortality (M) varies with age (expressed in number of winter rings) according to the following:

| Rings | M |
| :--- | :--- |
| 1 | 1 |
| 2 | 0.3 |
| 3 | 0.2 |
| $4+$ | 0.1 |

Those values have been held constant from 1957 to date. Those values correspond to estimates for North Sea herring based on recommendations by the Multi-species WG (Anon. 1987a) that were applied to adjacent areas (Anon. 1987b).

## B.3. Surveys

## B.3.1 Acoustic survey

An acoustic survey has been carried out for VIa (N) herring in the years 1987, 1991-2003. The 1997 survey was invalidated due to its unusual timing (June as oppose to July).

Biomass estimated from the acoustic survey tends to be variable. Herring are found in similar area each year, namely south of the Hebrides off Barra Head, west of the Hebrides and along the shelf edge.

The stock is highly contagious in its spatial distribution, which explains some of the high variability in the time series. Effort stratification has improved with knowledge of the distribution and this may be less of a problem in more recent years. The survey uses the same target strength as for the North Sea surveys and there is no reason to suppose why this should be any different. Species identification is generally not a great problem.

## B.3.2 Larvae survey

Larvae surveys for this stock were carried out from 1973 to 1993. Larval production estimates (LPE) and a larval abundance index (LAI) were produced for the time series. These values were used in the assessment, the LPE until 2001. However, in 2002 it was decided that the LAI had no influence on the assessment and has not been used since. Documentation of this survey time-series is given in ICES CM 1990/H:40.
B.4. Commercial CPUE Not used for pelagic stocks

## B.5. Other relevant data

## C. Historical Stock Development

An experimental survey-data-at-age model was formulated at the 2000 HAWG. In 1999 and 1998 a Bayesian modification to ICA was used to account for the uncertainty in misreporting.

## Model used: ICA

Software used: ICA (Patterson 1998b)
Model Options chosen:

- Separable constraint over last 8 years (weighting $=1.0$ for each year)
- Reference age $=4$
- Constant selection pattern model
- Selectivity on oldest age $=1.0$
- First age for calculation of mean $\mathrm{F}=3$
- Last age for calculation of mean $F=6$
- Weighting on 1-rings $=0.1$; all other age classes $=1.0$
- Weighting for all years $=1.0$
- All indices treated as linear
- No S/R relationship fitted
- Lowest and highest feasible $F=0.02$ and 0.5
- All survey weights fitted by hand i.e., 1.0 with the 1 ringers in the acoustic survey weighted to 0.1 .
- Correlated errors assumed i.e., $=1.0$

No shrinkage applied

Input data types and characteristics:

| Type | Name | Year range | Age range | Variable from year <br> to year <br> Yes/No |
| :--- | :--- | :--- | :--- | :--- |

## D. Short-Term Projection

Model used: Age structured

Software used: MFDP ver 1a

Initial stock size: Taken from the last year of the assessment. 1- and 2-ring recruits taken from a geometric mean for the years 1976 to one year prior to the last year.

Maturity: Mean of the last three years of the maturity ogive used in the assessment.
F and M before spawning: Set to 0.67 for all years.
Weight at age in the stock: Mean of the last three years in the assessment.
Weight at age in the catch: Mean of the last three years in the assessment.

Exploitation pattern: Mean of the previous three years, scaled by the Fbar (3-6) to the level of the last year.
Intermediate year assumptions: status quo F constraint.
Stock recruitment model used: None used
Procedures used for splitting projected catches: Not relevant

## E. Medium-Term Projections

Model used: ICP as described in ICES 1996/ACFM:10

Software used: ICP (Patterson 1999)?
Initial stock size: Population parameters (vector of abundance at age in 2003, fishing mortality at reference age in 2003, selection at age) are drawn from a multivariate normal distribution with mean equal to the values estimated in the stock assessment model, and with covariance as estimated in the same model fit. Geometric mean recruitment for 1- and 2ringers is used to replace the values in the assessment for the first projected year, however, the covariance values produced by ICA are retained.

Natural mortality: Mean of the last three years in the assessment.

Maturity: Mean of the last three years of the maturity ogive used in the assessment.
F and M before spawning: Set to 0.67 for all years.

Weight at age in the stock: Mean of the last three years in the assessment.

Weight at age in the catch: Mean of the last three years in the assessment.

Exploitation pattern: ???
Intermediate year assumptions: F or TAC constraint
Stock recruitment model used: Ockham option using the converged VPA 1972 to three years prior to last year in the assessment.

Uncertainty models used:

1. Initial stock size:
2. Natural mortality:
3. Maturity:
4. $F$ and $M$ before spawning:
5. Weight at age in the stock:
6. Weight at age in the catch:
7. Exploitation pattern:
8. Intermediate year assumptions:
9. Stock recruitment model used:
F. Long-Term Projections

Model used:

Software used:

Maturity:

F and M before spawning:
Weight at age in the stock:

Weight at age in the catch:

Exploitation pattern:
Procedures used for splitting projected catches:

## G. Biological Reference Points

The report of SGPRP (ICES 2003/ACFM:15) proposed a $\mathbf{B}_{\lim }$ of $50,000 t$ for VIa (N) herring. This is calculated from the values in the converged part of the VPA (1976-1999) and the Working Group endorsed this value in 2003 (ICES 2003/ACFM:17).

In 2003 the Working Group estimated retrospective error in terminal SSB from 4 years and gave a mean of the absolute values of $20 \%$ and a maximum of $38 \%$. Since there are so few data points and they are close in time to the current year the maximum value might be an underestimate of the range of values. The Working Group felt that the $90^{\text {th }}$ percentile on a normal distribution that had a mean error of $20 \%$ might be a more appropriate measure; this would give a factor close to $50 \%$.
$\mathbf{B}_{\mathrm{pa}}=\mathbf{B}_{\mathrm{lim}} * 1.50$ and gives $\mathbf{B}_{\mathrm{pa}}=75,000 \mathrm{t}$
The Working Group had considerable trouble developing F reference points but proposed a value based on rather limited data on errors of estimation. $\mathbf{F}_{\text {lim }}$ was derived directly from the equilibrium exploitation rate for an SSB for $\mathbf{B}_{\mathrm{lim}}$. $\mathbf{F}_{\mathbf{p a}}$ was obtained in a similar manner to $\mathbf{B}_{\mathbf{p a}}$ with a factor of $50 \%$. Full details of the method are given in last year's Working Group report.

The Working Group did not repeat the extensive analysis carried out in 2003 (ICES 2003/ACFM:17) but suggests that, at the very least, a $\mathbf{B}_{\mathrm{lim}}$ of 50,000 and a $\mathbf{B}_{\mathrm{pa}}$ of 75,000 are suitable as Biomass limit and reference points for VIa (N). Reference points are urgently needed for the management of this stock and these values are as well founded as many others currently in use.

## Suggested Precautionary Approach reference points:

| $\mathbf{B}_{\text {lim }}$ is $50,000 \mathrm{t}$ | $\mathbf{B}_{\mathrm{pa}}$ be set at $75,000 \mathrm{t}$ |
| :--- | :--- |
| $\mathbf{F}_{\text {lim }}$ is 0.75 | $\mathbf{F}_{\mathrm{pa}}=0.35$ |

## Technical basis:

| $\mathbf{B}_{\mathrm{lim}}: \mathbf{B}_{\text {loss }}$ Estimated SSB for sustained recruitment | $\mathbf{B}_{\mathrm{pa}}:=1.5 * \mathbf{B}_{\mathrm{lim}}$ |
| :--- | :--- |
| $\mathbf{F}_{\text {lim }}$ corresponding to $\mathbf{B}_{\mathrm{lim}}$ from the yield-per-recruit <br> $\mathbf{F}_{\mathrm{lim}}=0.75$ | $\mathbf{F}_{\mathrm{pa}}=0.5 * \mathbf{B}_{\mathrm{lim}}$ |

## H. Other Issues

## H. 1 Terminology

The WG uses "rings" rather than "age" or "winter rings" throughout the report to denominate the age of herring, with the intention to avoid confusion. It should be observed that, for autumn spawning stocks, there is a difference of one year between "age" and "rings". HAWG in 1992 (ICES 1992/Assess:11) stated that
"The convention of defining herring age rings instead of years was introduced in various ICES working groups around 1970. The main argument to do so was the uncertainty about the racial identity of the herring in some areas. A herring with one winter ring is classified as 2-years-old if it is an autumn spawner, and one-year-old if it is a spring spawner. Recording the age of the herring in rings instead of in years allowed scientists to postpone the decision on year of birth until a later date when they might have obtained more information on the racial identity of the herring.

The use of winter rings in ICES working groups has introduced a certain amount of confusion and errors. In specifying the age of the herring, people always have to state explicitly whether they are talking about rings or years, and whether the herring are autumn- or spring spawners. These details tend to get lost in working group reports, which can make these reports confusing for outsiders, and even for herring experts themselves. As the age of all other fish species (and of herring in other parts of the world) is expressed in years, one could question the justification of treating WestEuropean herring in a special way. Especially with the present trend towards multispecies assessment and integration of ICES working groups, there might be a case for a uniform system of age definition throughout all ICES working groups.

However, the change from rings to years would create a number of practical problems. Data files in national laboratories and at ICES would have to be adapted, which would involve extra costs and manpower. People that had not been aware of the change might be confused when comparing new data with data from old working group reports. Finally, in some areas (notably Division IIIa), the distinction between spring- and autumn spawners is still hard to make, and scientists preferred to continue using rings instead of years.

The Working Group discussed at length the various consequences of a change from rings to years. The majority of the Group felt that the advantages of such a change did not outweigh the disadvantages, and it was decided to stick to the present system for the time being."

The text table below gives an example for the correlation between age, rings and year class for the different spawning types in late 2002 :

| Year class (autumn spawners) | 2001/2002 | 2000/2001 | 1999/2000 | $1998 / \mathbf{1 9 9 9}$ |
| :--- | ---: | ---: | ---: | ---: |
| Rings | $\mathbf{0}$ | $\mathbf{1}$ | $\mathbf{2}$ | $\mathbf{3}$ |
| Age (autumn spawners) | 1 | 2 | 3 | 4 |
| Year class (spring spawners) | $\mathbf{2 0 0 2}$ | $\mathbf{2 0 0 1}$ | $\mathbf{2 0 0 0}$ | $\mathbf{1 9 9 9}$ |
| Rings | $\mathbf{0}$ | $\mathbf{1}$ | $\mathbf{2}$ | $\mathbf{3}$ |
| Age (spring spawners) | 0 | 1 | 2 | 3 |

## ANNEX: Herring in VIaS and VIIb

Stock specific documentation of standard assessment procedures used by ICES.

Stock: Herring in VIaS and VIIb
Working Group: Herring Assessment Working Group for the area south of $62^{0} \mathrm{~N}$
Date: $\quad 19^{\text {th }}$ April 2004

## A. General

## A.1. Stock definition

The herring to the northwest of Ireland comprise both autumn and winter spawning components. For the purpose of stock assessment and management, these areas have been separated from VIaN since 1982. Spawning in VIIb has traditionally taken place in the autumn and in VIaS, later in the autumn and in the winter.

## A.2. Fishery

The TAC is taken mainly by Ireland, which has over $90 \%$ of the quota. In recent years, only Ireland has exploited herring in this area. In 2000 the Irish North West Pelagic Management Committee was established to deal with the management of this stock.

Landings have decreased markedly from about 44,000 t in 1990 to around 13,000 t in 2003.

## A.3. Ecosystem aspects

## B. Data

## B.1. Commercial catch

The commercial catches are provided by national laboratories belonging toe the nations that have quota for this stock. In recent years, only Ireland has caught herring in this area, so catch-at-age, mean weights and stock weights are derived entirely from Irish sampling. Sampling is performed as part of commitments under the EU Council Regulation 1639/2001.

Commercial catch at age data are submitted in Exchange sheet v 1.6.4. These data are usually processed using SALLOCL. This program (Patterson, 1998) gives outputs on sampling status and available biological parameters and documents actions taken to raise unsampled metiers using other data sets. The species co-ordinator allocates samples of catch numbers, mean length and mean weight-at-age to unsampled catches using appropriate samples by gear (fleet) area quarter and if an exact match is not available then a neighbouring area if the fishery extends to this area in the same quarter.

## B.2. Biological

Mean weights at age in the catch in the $4^{\text {th }}$ and $1^{\text {st }}$ quarter are used as stock weights.

## B.3. Surveys

Not used in assessment

Stock: Irish Sea herring<br>Working Group Herring Assessment Working Group (HAWG)

Date:
17 March 2004

## A. General

## A.1. Stock definition

Herring spawning grounds in the Irish Sea are found in coastal waters to the west and north of the Isle of Man and on the Irish Coast at around $54^{\circ} \mathrm{N}$ (ICES 1994, Dickey-Collas et al. 2001). Spawning takes place from September to November in both areas, occurring slightly later on average on the Irish Coast than off the Isle of Man. ICES Herring Assessment Working Groups from 19XX to 1983 used vertebral counts to separate catches into Manx and Mourne stocks associated with these spawning grounds. However, taking account of inaccuracies in this method and the results of biochemical analyses, the 1984 WG combined the data from the two components to provide a "more meaningful and accurate estimate of the total stock biomass in the N.Irish Sea." All subsequent assessments have treated the VIIa(N) data as coming from a single stock. During the 1970s, catches from the Manx component were about three times larger than those from the Mourne component. By the early 1980s, following the collapse of the stock, the catches were of similar magnitude. The fishery off the Mourne coast declined substantially in the 1990s then ceased, whilst acoustic and larva surveys in this period indicate that the spawning population in this area has been very small compared to the biomass off the Isle of Man.

The occurrence in the Irish Sea of juvenile herring from a winter-spring spawning stock has been recognized since the 1960s based on vertebral counts (ICES 1994). More recently, Brophy and Danilowicz (2002) used otolith microstructure to show that nursery grounds in the western Irish Sea were generally dominated by winter-spawned fish. Samples from the eastern Irish Sea were mainly autumn-spawned fish. Recaptures from 10,000 herring tagged off the SW of the Isle of Man in July 1991 occurred both on the Manx spawning grounds and along the Irish Coast with increasing proportions from the Celtic Sea in subsequent years (Molloy et al., 1993). The pattern of recaptures indicated a movement towards spawning grounds in the Celtic Sea as the fish matured.

A proportion of the Irish Sea herring stocks may occur to the north of the Irish Sea outside of the spawning period. This was indicated by the recapture on the Manx spawning grounds of 3-6 ring herring tagged during summer in the Firth of Clyde (Morrison and Bruce 1981). Aggregations of post-spawning adult herring were detected along the west coast of England during an acoustic survey in December 1996 (Department of Agriculture and Rural Development for Northern Ireland, unpublished data), showing that a component of the stock may remain within the Irish Sea.

A recent EU-funded programme WESTHER aims to elucidate stock structures of herring throughout the western seaboard of the British Isles using a combination of morphometric measurements, otolith structure, genetics and parasite loads. The results of this should provide the best-available information on mixing of stocks within and beyond the Irish Sea.

## A.2. Fishery

There have been three types of fishery on herring in the Irish Sea in the last 40 years:
i) Isle of Man- aimed at adult fish that spawn around the Isle of Man.
ii) Mourne- aimed at adult fish that spawn off the Northern Irish eastern coast.
iii) Mornington- a mixed industrial fishery that caught juveniles in the western Irish Sea.

The Mornington fishery started in 1969 and at its peak it caught 10,000 tonnes per year. It took place throughout the year. The fishery was closed due to management concerns in 1978 (ICES, 1994). In the 1970s the catch of fish from the Mourne fishery made up over a third of the total Irish Sea catch. The fishery was carried out by UK and Republic of Ireland vessels using trawls, seines and drift nets in the autumn. However the fishery declined and ceased in the early 1990s (ICES, 1994). The biomass of Mourne herring, determined from larval production estimates is now $2-4 \%$ of the total Irish Sea stock (Dickey-Collas et al., 2001).

The main herring fishery in the Irish Sea has been on the fish that spawn in the vicinity of the Isle of Man. The fish are caught as they enter the North Channel, down the Scottish coast, and around the Isle of Man. Traditionally this fishery supplied the Manx Kipper Industry, which requires fish in June and July. However the fish appeared to spawn slightly later in the year in the 1990s and this lead to problems of supply for the Manx Kipper Industry. In 1998 the Kipper companies decided to buy in fish from other areas. Generally the fishery has occurred from June to November, but is highly dependent on the migratory behaviour of the herring.

The fishery has been prosecuted mainly by UK and Irish vessels. TACs were first introduced in 1972, and vessels from France, Netherlands and the USSR also reported catches from the Irish Sea during the 1970s before the closure of the fisheries from 1978 to 1981. By the 1990s only the fishery on the Manx fish remained, and by the late 1990s this was dominated by Northern Irish boats. The number of Northern Irish vessels landing herring declined from 24 in 1995-96 to 610 in 1997-99 and to 4 in 2000. Only two vessels operated in 2002 and 2003. However, total landings have remained relatively stable since the 1980s whilst the mean amount of fish landed per fishing trip has increased, reflecting the increase in average vessel size

## A.3. Ecosystem aspects

The main fish predators on herring in the Irish Sea include whiting (Merlangius merlangus), hake (Merluccius merluccius) and spurdogfish (Squalus acanthias). The size composition of herring in the stomach contents indicates that predation by whiting is mainly on 0 -ring and 1 -ring herring whilst adult hake and spurdogfish also eat older herring (Armstrong, 1979; Newton, 2000; Patterson, 1983). Sampling since the 1980s has shown cod (Gadus morhua), taken by both pelagic and demersal trawls in the Irish Sea, to be minor predators on herring. Small clupeids are an important source of food for piscivorous seabirds including gannets, guillemots and razorbills (ref...) which nest at several locations in and around the Irish Sea. Marine mammal predators include grey and harbour seals (ref.) and possibly pilot whales, which occur seasonally in areas where herring aggregate.

Whilst small juvenile herring occur throughout the coastal waters of the western and eastern Irish Sea, their distribution overlaps extensively with sprats (Sprattus sprattus). The biomass of small herring has typically been less than $5 \%$ of the combined biomass of small clupeids estimated by acoustics (ICES HAWG reports).

## B. Data

## B.1. Commercial catch

## National landings estimates

The current ICES assessment of Irish Sea herring extends back to 1961, and is based on landings only. ICES WG reports (ICES 1981, 1986 and 1991) highlight the occurrence of discarding and slippage of catches, which can occur in areas where adult and juvenile herring co-occur. Discarding has been practised on an increasing scale since 1980 (ICES 1986). This increase is primarily related to the onset of slippage of catches that coincided with the cessation of the industrial fishery in early 1979 (ICES 1980). As a result of sorting practices, slippage has led to marked changes in the age composition of the catch since 1979 and considerable change in the mean weights at age in the catch of the three youngest age groups (ICES 1981). Estimates of discarding were sporadically performed in the 1980s (ICES 1981, 1982, 1985 and 1986), but there are no estimates of discarding or slippage of herring in the Irish Sea fisheries since 1986. Highly variable annual discard rates are evident from the 1980s surveys. For example, discards estimates of juvenile herring (0-group) for the Mourne stock
taken in the 1981 Nephrops fishery was estimated at $1.9 \times 10^{6}$ of vessels landing in Northern Ireland, which amounts to approximately $20 \%$ of the Mourne fishery (ICES 1982). In 1982, at least $50 \%$ of 1 -group herring caught were discarded at sea by vessels participating in the Isle of Man fishery (ICES 1983). A more comprehensive survey programme to determine the rate of discarding in 1985 revealed discard estimates of $82 \%$ by numbers of 1-ring fish, $30 \%$ of 2 -ring and $6 \%$ of 3-ring fish, with the dominant age group in the landed catch being 3 ring (ICES 1986). A similar survey in 1986, however, found the discarding of young fish fell to a very low level (ICES 1987). The 1991 WG discussed the discard problem in herring fisheries in general and suggested possible measures to reduce discarding. No quantitative estimates were given, but reports of fishermen suggesting discards of up to $50 \%$ of catch as a result of sorting practices by using sorting machines (ICES 1991). The variation in discard rates since 1980, as a result of changes in discard practices, can probably be attributed to several changes in the management of the fishery. These include the availability of different fishing areas, the change to fortnightly catch quotas per boat (ICES 1987) and level of TAC, where lower discard rates are observed with a higher TAC (ICES 1989). The level of slippage is also related to the fishing season, since slippage is often at a high level in the early months (ICES 1987). Due to the variable nature of discard estimates and the lack of a continuous data series, it has not been included in the annual catch at age estimates (with the exception of the 1983 assessment when the catch in numbers of 1ringers was doubled based on a $50 \%$ discard estimate of this age group).

Landings data for herring in Division $\mathrm{VIIa}(\mathrm{N})$ are generally collated from all participating countries providing official statistics to ICES, namely UK (England \& Wales, Northern Ireland, Scotland and the Isle of Man), Ireland, France, the Netherlands and what was formally the USSR. The data for the period 1971 to present are reported in the various Herring Assessment Working Group Reports and are reproduced in Table 1. The official Statistics for Irish landings from VIIa have been processed to remove data from the Dunmore East fishery in area VIIa(S), and represent landings from VIIa(N) only.

Over the past three decades, the WG highlighted the under- or misreporting of catches as the major problem with regards to the accuracy of the landing data. Related to this are the problems of illegal landings during closed periods and paper landings. Area misreporting was also recognised (ICES 1999), although a less prominent problem that is mostly corrected for.

The 1980 WG first identified the problem of misreporting of landings based on the results of a 3-year sampling programme, which was initiated after 1975 when herring were being landed in metric units at ports bordering the Irish Sea (1 unit = 100 kg nominal weight). The study showed the weight of a unit to be very variable, but was usually well in excess of 100 kg . An initial attempt to allow for misreporting using adjusted catches made very little difference to any of the values of fishing mortality (ICES 1980). Subsequently, despite serious concerns about considerable under-reporting being raised (ICES 1990, 1994, 2000 and 2001), the WG made no attempts to examination the extent of the problem. This uncertainty signifies no estimates of under-reporting and consequently no allowance for under-reporting of landings has been made. Considerable doubt was raised as to the accuracy of landing data over the period 1981-87 (ICES 1994). However, after apparent reexamination all WG landing statistics are assumed to be accurate up to 1997 (ICES 2000), but with no reliable estimates of landings from 1998-2000 (ICES 2001). The WG acknowledged that poor quality landing data bring the catch in numbers at age data into question and hence the accuracy of any assessment using data from such periods (ICES 1994).

In 2002 the ICES assessment was extended back to include data for 1961-1970 with the intention of showing the stock development prior to the large expansion in fishing effort and stock size in the early 1970s. This has now been extended further back to 1955. Landings data for this period were extracted from the UK fisheries data bases (England \& Wales, Scotland and Northern Ireland: Table 1, columns8-10) and publications by Bowers and Brand (1973) for Isle of Man landings (column 11). Landings data for Ireland and France were not available.

To estimate the VIIa(N) herring landings for Ireland and France during 1955-1970, the NE Atlantic herring catches for each country were obtained from the FAO database (column 16). Using the ICES landings data for each country (column 17) the mean proportion of the VIIa(N) catch to the NE Atlantic catch during 1971 to 1981 was estimated (column 18). This was applied to the NE Atlantic catches from each country, for the period 1955 to 1970, to give an estimated landing for both France and Ireland (column 19). These landings were added to the known catches from the CEFAS database to give the total landings. The landings data (tonnes) used in the assessment are given in Table 1, column 14. It is anticipated that landings data for VIIa(N) for years prior to 1971 can be extracted from the Irish databases. However, the French landings will remain as estimates.
[Need discussion on magnitude of errors in the old data]
[Need discussion on errors due to misreporting]

## Catch at age data

Age classes in the ICES Canum file refer to numbers of winter rings in otoliths. As the Irish Sea stock comprises autumn spawners, $i$-ring fish taken in year $y$ will comprise fish in their $i_{\text {th }}$ year of life if caught prior to the spawning season and $(i+1)_{\mathrm{th}}$ year if caught after the spawning period. An $i$-ring fish will belong to year-class $y$ - 2 . As spawning stock is estimated at spawning time (autumn), spawning stock and recruitment relationships require estimates of recruitment of $i$-ring fish in year $y$ and estimates of SSB in year $i-2$. The current assessment estimates recruitment as numbers of 1-ring fish.

The most recent description of sampling and raising methods for estimating catch at age of herring stocks is in ICES (1996). This includes sampling by UK(E\&W) and Ireland, but not UK(NI) and Isle of Man
$\mathrm{UK}(\mathrm{NI})$ : A random sample of $10-20 \mathrm{~kg}$ of herring is taken from each landing into the main landing port (Ardglass) by the NI Department of Agriculture and Rural Development. Samples are also collected from any catches landed into Londonderry. Prior to the 1990 s, the samples were mostly processed fresh. During the 1990 s, there was an increasing tendency for samples to be frozen for a period of weeks before processing. No corrections have been applied to weight measurements to allow for changes due to freezing and defrosting. The length frequency (total length) of each sample is recorded to the nearest 0.5 cm below. A sample of herring is then taken for biological analysis as follows: one fish per 0.5 cm length class, followed by a random sample to make the sample up to 50 fish.

Otoliths are removed from each fish, mounted in resin on a black slide and read by reflected light. Ages are assigned according to number of winter rings.

Length frequencies (LFDs) for VIIa(N) catches are aggregated by quarter. The weight of the aggregate LFD is calculated using a length-weight relationship derived from the biological samples. The LFD is then raised to the total quarterly landings of herring by the NI fleets. A quarterly age-length key, derived from commercial catch samples only, is applied to the raised LFD to give numbers at age and mean weight at age.
IOM: IOM sampling covers the period 1923-1997. Samples are collected from any landings into Peel, by staff of the Port Erin Marine Laboratory (Liverpool University). The sampling and raising procedures are the same as described for UK(NI) with the following exceptions: i) the weight of the aggregate quarterly LFD is obtained from the original sample weights rather than using a length-weight relationship, and ii) the biological samples are random rather than stratified by length. The 1993 ICES herring assessment WGs noted a potential underestimation by one ring, of herring sampled in the IOM. This was caused by a change in materials used for mounting otoliths and appears to have been a problem for ageing older herring in 1990-92. This was since rectified. However, the bias for the 1990-92 period has not yet been quantified and will be examined in the near future.

Ireland: Irish sampling of VIIa(N) herring covers the period 19xx - 2001. Some samples are from landings into NI but transported to factories in southern Ireland. Irish sampling schemes for herring in Div. VIa(S), VIIb, Celtic Sea and VIIj are described in ICES (1996). Methods for sampling catches in VIIa(N) are similar. The procedure is the same as described above for UK(NI) except that the biological samples are random rather than length stratified. ICES (1996) notes that a length-stratified scheme should be adopted to ensure proper coverage at the extremes of the LFDs.

Quality control of herring ageing has fallen under the remit of EU funded programmes EFAN and TACADAR, to which the laboratories sampling VIIa(N) herring contribute. An otolith exchange exercise was initiated in 2002 and is currently being completed.

## B.2. Biological

Natural mortality (M) varies with age (expressed in number of winter rings) according to the following:

| Rings | M |
| :--- | :--- |
| 1 | 1 |
| 2 | 0.3 |
| 3 | 0.2 |
| $4+$ | 0.1 |

Those values have been held constant from 1972 to date. Those values correspond to estimates for North Sea herring based on recommendations by the Multi-species WG (Anon. 1987a). which were applied to adjacent areas (Anon. 1987b).

Maturity at age. Combined, year-specific maturity ogives were used in the 2003 Assessment (ICES 2003). The way those values were derived is documented on Dickey-Collas et al. (2003). Prior to 2003 annually invariant estimates of the proportion of fish mature by age were used. Those were based on estimates from the 1970s (ICES, 1994). The use of the variable maturity ogive in 2003 did not change greatly the perception of the stock state (Dickey-Collas et al., op cit).

SSB in September is estimated in the assessment. The survey larvae estimate is used as a relative index of SSB. The proportions of M and F before spawning are held constant over time in the assessment.

Stock weights at age have been derived from the age samples of the 3rd quarter landings since 1984 (R. Nash pers comm.). The stock mean weights for 1975-83 are time invariant and were re-examined in 1985 (Anon. 1985). They result from combining Manx and Mourne data sets. The weight at age of those stocks were considered relatively stable over time.

## B.3. Surveys

The following surveys provide data for the VIIa(N) assessment:

| Survey Acronym | Type | Abundance data | Area and Month | Period |
| :---: | :---: | :---: | :---: | :---: |
| AC(VIIaN) | Acoustic survey | Numbers at age (1-ring and older); SSB | VIIa(N) from $53^{0} 20^{\prime} \mathrm{N}$ $55^{\circ} \mathrm{N}$; September | 1994 - present |
| NINEL | Larva survey | Production of larvae at 6 mm TL | $\mathrm{VIIa}(\mathrm{N})$ from $53^{\circ} 50^{\prime} \mathrm{N}$ $54^{\circ} 50$ ' N ; November | 1993 - present |
| DBL | Larva survey | Production of larvae at 6 mm TL | East coast of Isle of Man; October | $\begin{aligned} & 1989-1999(1996 \\ & \text { missing) } \end{aligned}$ |
| GFS-oct | Groundfish survey | Mean nos. caught per 3 n.miles ( $1 \& 2$ ringers), by region | $\mathrm{VIIa}(\mathrm{N})$ from $53^{0} 20^{\prime} \mathrm{N}-54^{\circ}$ $50^{\prime} \mathrm{N}$ (stratified); October | 1993 - present |
| GFS-mar | Groundfish survey | Mean nos. caught per 3 n.miles ( $1 \& 2$ ringers), by region | $\begin{aligned} & \mathrm{VIIa}(\mathrm{~N}) \text { from } 53^{0} 20^{\prime} \mathrm{N}-54^{\circ} \\ & 50^{\prime} \mathrm{N} \text { (stratified); March } \end{aligned}$ | 1993 - present |

Data from a number of earlier surveys have been documented in the ICES WG reports. These include:

NW Irish Sea young herring surveys (Irish otter trawl survey using commercial trawler; 1980-1988)
Douglas Bank (East Isle of Man) larva surveys (ring net surveys; 1974-1988) (Port Erin Marine Lab)
Douglas Bank spawning aggregation acoustic surveys (1989, 1990, 1994, 1995) (Port Erin Marine Lab)
Western Irish Sea acoustic survey ( July 1991, 1992) (UK(NI))
Eastern Irish Sea acoustic survey (December 1996)

Surveys used in recent assessments are described below.

## AC(VIIaN) acoustic survey

This survey uses a stratified design with systematic transects, during the first two weeks of September. Vessel used is the R.V. Lough Foyle (UK(NI)). Starting positions are randomized each year (see recent HAWG reports for transect design and survey results). The survey is most intense around the Isle of Man ( 2 to 4 n.mile transect spacing) where highest densities of adult herring are expected based on previous surveys and fishery data. Transect spacing of 6 to 10 n.miles are used elsewhere. A sphere-calibrated EK-500 38 kHz sounder is employed, and data are archived and analysed using Echoview (SonarData, Tasmania). Targets are identified by midwater trawling. Acoustic records are manually partitioned to species by scrutinising the echograms and using trawl compositions where appropriate. ICES-recommended target strengths are used for herring, sprat, mackerel, horse mackerel and gadoids. The survey design and implementation follows, where possible, the guidelines for ICES herring acoustic surveys in the North Sea and West of Scotland. The survey data are
analysed in 15-minute elementary distance sampling units (approx. 2.5 n.miles). An estimate of density by age class, and spawning stock biomass, is obtained for each EDSU and a distance-weighted average calculated for each stratum. These are raised by stratum area to give population numbers and SSB by stratum.

## NINEL larva survey

The DARD herring larva survey has been carried out in November each year since 1993. Sampling is carried out on a systematic grid of stations covering the spawning grounds and surrounding regions in the NE and NW Irish Sea (Figure 1). Larvae are sampled using a Gulf-VII high-speed plankton sampler with $280 \mu \mathrm{~m}$ net. Double-oblique tows are made to within 2 m of the seabed at each station. Internal and external flow rates, and temperature and salinity profiles, were recorded during each tow. Lengths of all herring larva captured are recorded.

Mean catch-rates (nos. $\mathrm{m}^{-2}$ ) are calculated over stations to give separate indices of abundance for the NE and NW Irish Sea. Larval production rates (standardised to a larva of 6 mm ), and birth-date distributions, are computed based on the mean density of larvae by length class. A growth rate of $0.35 \mathrm{~mm} \mathrm{day}^{-1}$ and instantaneous mortality of 0.14 day $^{-1}$ are assumed based on estimates made in 1993-1997. More recent studies have indicated a mortality rate of 0.09 , and this value is also applied to examine the effect on trends in estimates of larval production

## DBL larva survey

Herring larvae were sampled on the east side of the Isle of Man in September or October each year. Double oblique tows with a 60 cm Gulf VII/PRO-NET high-speed plankton sampler with a 40 cm aperture nose cone were undertaken on a 5 Nm square grid. The tow profile was followed with a FURUNO net sonde attached to the top of the equipment. The volume of water filtered was calculated from the nose cone mouth flow meter. The samples were preserved in $4 \%$ seawater buffered formalin and stored in 70\% alcohol.

All herring larvae were sorted from the samples. The numbers of larvae per $\mathrm{m}^{3}$ were calculated from the volume of water filtered and the number of larvae per tow. Up to 100 larvae from each tow were measured with an ocular graticule in a stereo microscope. Each sample was assigned to a sampling square and the total number of larvae per 0.5 mm size class calculated from the average depth of the square and the surface area.

The total production and time of larvae hatch was calculated using an instantaneous mortality coefficient (k) of 0.14 and a growth rate of $0.35 \mathrm{~mm} \mathrm{~d}^{-1}$ in the formula:

$$
N_{t}=N_{o} e^{-(k t)}
$$

Production was calculated as the sum of all size classes/hatching dates. Spawning dates were taken as 10 days prior to the hatching date (Bowers 1952).

## GFS-oct and -mar groundfish surveys

The DARD groundfish survey of ICES Division VIIaN are carried out in March and October 2003 at standard stations between $53^{\circ} 20^{\prime} \mathrm{N}$ and $54^{\circ} 45^{\prime} \mathrm{N}$ (Figure 2). Data from additional stations fished in the St George's Channel since October 2001 have not been used in calculating herring indices of abundance. As in previous surveys, the area was divided into strata according to depth contour and sediment type, with fixed station positions (note that the strata in Fig. 2 differ from those in the September acoustic survey shown in Fig. 1). The sampling gear was a Rockhopper otter trawl fitted with nonrotating rubber discs of approximately 15 cm diameter on the footrope. The trawl fishes with an average headline height of 3.0 m and door spread of $30-40 \mathrm{~m}$ depending on depth and tide. A 20 mm stretched-mesh codend liner was fitted. During March, trawling was carried out at an average speed of 3 knots across the ground, over a standard distance of 3 nautical miles at standard stations and 1 nautical mile in the St. George's Channel. Since 2002, all survey stations in the October survey have been of 1-mile distance. Comparative trawling exercises during the October surveys and during an independent exercise in February 2003 indicate roughly similar catch-rates per mile between 1-mile and 3-mile tows. It is planned to continue with some comparative trawling experiments during future surveys to improve the statistical power of significance tests between the 1 -mile and 3-mile tows.

As the surveys are targeted at gadoids, ages were not recorded for herring. The length frequencies in each survey were sliced into length ranges corresponding to 0 -ring and 1 -ring herring according to the appearance of modes in the overall weighted mean length frequency for each survey. Some imprecision will have resulted because of the overlap in length-atage distributions of 1-ring and 2-ring herring. The error is considered to be comparatively small for most of the surveys where clear modes are apparent. There was no clear division between 1-ring and 2-ring herring in the March 2003 groundfish survey, and the estimate for 1-ringers may include a significant component of small 2 -ringers. The arithmetic mean catch-rate and approximate variance of the mean was computed for each age-class in each survey stratum, and averaged over strata using the areas of the strata as weighting factors.

## B.4. Commercial CPUE

Commercial CPUE's are not used for this stock.
B.5. Other relevant data

## C. Historical Stock Development

Model used: ICA
Software used: ICA (Patterson 1998)
Model Options chosen:

- Separable constraint over last 6 years (weighting $=1.0$ for each year)
- Reference age $=4$
- Constant selection pattern model
- Selectivity on oldest age $=1.0$
- First age for calculation of mean $F=2$
- Last age for calculation of mean $F=6$
- Weighting on 1 -rings $=0.1$; all other age classes $=1.0$
- Weighting for all years $=1.0$
- All indices treated as linear
- No S/R relationship fitted
- Lowest and highest feasible $\mathrm{F}=0.05$ and 2.0
- All survey weights fitted by hand i.e., 1.0 with the 1 ringers in the acoustic survey weighted to 0.1 .
- Correlated errors assumed i.e., $=1.0$
- No shrinkage applied

Input data types and characteristics:

| Type | Name | Year range | Age range | Variable from year to year Yes/No |
| :---: | :---: | :---: | :---: | :---: |
| Caton | Catch in tonnes | 1961-last data year | NA | Yes |
| Canum | Catch at age in numbers | 1961-last data year | 1-8+ | Yes |
| Weca | Weight at age in the commercial catch | $\begin{aligned} & \text { 1961-1971 } \\ & \text { 1972-1983 } \\ & \text { 1984-last data year } \end{aligned}$ | $\begin{aligned} & 1-8+ \\ & 1-8+ \\ & 1-8+ \\ & \hline \end{aligned}$ | $\begin{aligned} & \hline \text { Yes } \\ & \text { No } \\ & \text { Yes } \\ & \hline \end{aligned}$ |
| West | Weight at age of the spawning stock at spawning time. | $\begin{aligned} & 1961-1971 \\ & \text { 1972-1983 } \\ & \text { 1984-last data year } \\ & \hline \end{aligned}$ | $\begin{aligned} & 1-8+ \\ & 1-8+ \\ & 1-8+ \end{aligned}$ | $\begin{aligned} & \hline \text { Yes } \\ & \text { No } \\ & \text { Yes } \\ & \hline \end{aligned}$ |
| Mprop | Proportion of natural mortality before spawning | 1961-last data year | NA | No |
| Fprop | Proportion of fishing mortality before spawning | 11961-last data year | NA | No |
| Matprop | Proportion mature at age | 1961-last data year | 1-8+ | Yes |
| Natmor | Natural mortality | 1961-last data year | 1-8+ | No |

Tuning data:

| Type | Name | Year range | Age range |

## D. Short-Term Projection

## NOT USED IN 2004

Model used: Age structured
Software used: MFDP ver 1a

Initial stock size: Taken from the last year of the assessment. 1-ring recruits taken from a geometric mean for the years 1983 to two years prior to the current year. Where 1-ringers are absurdly estimated in the assessment 2-ringers are estimated as a geometric mean of the previous 10 year period.

Maturity: Mean of the previous three years of the maturity ogive used in the assessment.

F and $M$ before spawning: Set to 0.9 and 0.75 respectively for all years.
Weight at age in the stock: Mean of the previous three years in the assessment.

Weight at age in the catch: Mean of the previous three years in the assessment.

Exploitation pattern: Mean of the previous three years, scaled by the Fbar (2-6) to the level of the last year.
Intermediate year assumptions: TAC constraint.

Stock recruitment model used: None used

Procedures used for splitting projected catches: Not relevant

## E. Medium-Term Projections

## F. Long-Term Projections

Not done

## G. Biological Reference Points

Until there is confidence in the assessment the Working Group decided not to revisit the estimation of $\mathbf{B}_{\mathrm{pa}}(9,500 \mathrm{t})$ and $\mathbf{B}_{\text {lim }}$ ( $6,000 \mathrm{t}$ ). There were no new points to add to the discussions and deliberations presented in 2000 (ICES 2000/ACFM:10).

Figure 1. Sampling stations for larvae in the North Irish Sea (NINEL). Sampling is undertaken in November each year.

Figure 2. Standard station positions for DARD groundfish survey of the Irish Sea in March and October. Boundaries of survey strata are shown. Indices for the "Western Irish Sea" use data from strata 2 - 4. Indices for the "Eastern Irish Sea" use data from stratum 6 only (few juvenile herring are found in stratum 7). (Note different stratification to Fig. 1.). New stations fished in the St Georges Channel (strata 9 and 10) since October 2001 are not included in the survey indices. Stratum 5 ( 1 station only in recent years) is also excluded from the index. There are no stations in stratum 8 due to difficult trawling conditions for the gear used in the survey. Station 121 in stratum 7 has been fished only once and is excluded from the index.

## A. General

## A.1. Stock definition

Sprat in ICES area IV.

## A.2. Fishery

The Danish small meshed fishery is responsible for the majority of the landings. A study undertaken in 2000 showed that the species composition in the Danish sprat fishery has changed towards a fishery with low by-catches of other species (ICES CM 2001/ACFM:12). The Norwegian sprat fishery is carried out by purse- seiners. A closure of the Norwegian fishery was introduced for the second and third quarter in 1999 and this management regime is still in force. On top of this management regime, a maximum quota ( 900 t ) per vessel is set for the Norwegian vessels; and they are not allowed to fish in Norwegian waters until the Norwegian quota in EU waters has been taken. The majority of the catches in both fisheries is taken in the 4th quarter, though some fishery takes place during January and February.

There was a considerable increase in landings from about $10,000 \mathrm{t}$ in 1986 to a peak of $320,000 \mathrm{t}$ in 1995 . From 2000 the landings have been relatively stable around 150,000 to $170,000 \mathrm{t}$.

## A.3. Ecosystem aspects

## B. Data

## B.1. Commercial catch

The commercial catch is provided by the national laboratories belonging to nations exploiting the sprat in the North Sea. The sampling intensity for biological samples, i.e., age and weight-at-age is mainly performed following the EU regulation $1639 / 2001$ as the country landing most of the catches follows this regulation. This provision requires 1 sample per 2000 tonnes landed. This sampling level is lower than the guidelines ( 1 sample per 1000 tonnes) previously used by the HAWG, but as the fishery is carried out in a limited area, the recommended sampling level can be regarded as adequate.

The majority of commercial catch and sampling data are submitted in the Exchange sheet v. 1.6.4 and further processed with the SALLOCL-application (Patterson 1998). This program gives outputs on sampling status and available biological parameters and documents actions taken to raise unsampled metiers using other data sets. The species co-ordinator allocates samples of catch numbers, mean length and mean weight-at-age to unsampled catches using appropriate samples by gear (fleet) area quarter and if an exact match is not available then a neighbouring area if the fishery extends to this area in the same quarter.

## B.2. Biological

Mean weights at age in the catch in the $1^{\text {st }}$ quarter are used as stock weights.

Natural mortality. Results from the multi-species VPA (.Report from the ICES Workshop on Multi-species VPA in the North Sea, Charlottenlund, Denmark 8th-12th April 2002: ICES CM 2002/D:04 ) are used as a basis to fix the value of M in the CSA model. The estimated values presented in table XX correspond to predation mortality. To estimate total natural mortality a value of 0.2 to account for other sources of natural mortality should be added to the predation mortality.

## B.3. Surveys

The acoustic surveys for the North Sea Herring in June-July have estimated sprat abundance since 1996. In the initial years low sprat biomass was estimated but those were not thought to be representative mainly due to inappropriate coverage of the south-eastern area (ICES CM 2000/D:07), the area expected to have the highest abundance of sprat in the North Sea. In 2000 the survey was extended by 30 n.mi to the south and covered for the first time the south-eastern area considered to have the highest abundance of sprat in the North Sea. By doing so, the estimate of sprat increased significantly. The distribution pattern in 2002 demonstrates, however, that the southern distribution border was still not reached by the survey. Further, the inshore areas were sprat is expected to be abundant are not covered so, the survey can only be seen as indicative of trends in biomass.

The IBTS (February) sprat indices (no per hour) in IVb (sprat standard area) are used as an index of abundance. The historical data were revised in 1995 (ICES 1995/Assess:13) and 1999 (ICES 1999/ACFM:12). The IBTS Working Group redefined the sprat index to be calculated as an area weighted mean over means by rectangles for the entire North Sea sprat stock. Based on this, the IBTS WG asked ICES Secretariat to carry out new calculations in 2001 (ICES 2000/D:07), which are the ones used at present. The fishing method (gear) in the IBTS-survey was standardised in 1983 and the data series from 1984, are comparable. The old IBTS-indices are available in ICES 2001/ACFM:12.

## B.4. Commercial CPUE

Not used for this stock.

## B.5. Other relevant data

## C. Historical Stock Development

Model used:

Sprat is a relatively short-lived species, the stock and the catches, consisting mostly of 1 and 2 year-olds. In addition, there are difficulties in age reading resulting in unreliable estimates of numbers at age both from the surveys and the commercial catch. Given those limitations a data exploration using Catch-Survey Analysis (CSA), an assessment method designed for cases where full age-structured data are missing, was undertaken by the WG in 2003. The method is based on the "modified DeLury" two-stage model (Conser 1995) and on an implementation tested on simulated data presented to the Methods Working Group in 2003 (Mesnil 2003). The model assumes that the population consists of two stages: the recruits (preferably a single year-class) and the fully recruited ages.

Software used:

CSA executable version made available by B. Mesnil (IFREMER).

Model Options chosen:

Input data types and characteristics:

Model input data consisting of the time-series of catch numbers for each stage, mean weight for each stage in the stock at the start of the year and the $1^{\text {st }}$ quarter IBTS index of abundance for the 1 year-old sprat (age $=$ number of winter rings) and
older than 2 years-old. Given low sampling levels in years previous to 1995, constant weight at age based on commercial data from the $1^{\text {st }}$ quarter was assumed for the whole period. Reservations regarding the ability of the IBTS 1-year-old index to fully reflect strong and weak cohorts for sprat were expressed in previous WG reports (see ICES 1998 ACFM:14). Those were linked to difficulties in age reading and/or a possible prolonged spawning and recruitment season. Another problem identified in some surveys was related to large catches in small areas which could have been very influential on the results. Examination of the biomass and the 1 year-old index trajectories by the WG in 2003, suggested that the observed fluctuations in overall biomass are related to a large extent to observed fluctuations in the 1 year-old index. This is to be expected in a population where the recruits account for a large proportion of the stock. A unique value for the instantaneous rate of natural mortality $(M=0.4)$ and a parameter corresponding to the ratio of the survey catchability of the recruits to the fully recruited ages $(s=1)$ were fixed externally.

## D. Short-Term Projection

Model used:
The SHOT- approach (Shepherd, 1991) was used in the past by the WG to estimate the landings in the assessment year. The 2003 WG considered that approach inappropriate for a short-lived stock like sprat therefore the projection was based on the results from CSA.

A catch prediction for the assessment year is based on a linear regression of annual catch versus IBTS estimated biomass for the period starting in 1987.

Software used:

Initial stock size:

Maturity:
F and M before spawning:

Weight at age in the stock:
Weight at age in the catch:
Exploitation pattern:

Intermediate year assumptions:
Stock recruitment model used:

Procedures used for splitting projected catches:

## E. Medium-Term Projections

Not performed

## F. Long-Term Projections

Not performed

## G. Biological Reference Points

Not set.

## H. Other Issues

Only in-year catch forecasts are available. The stock consists of only a few year classes, with a predominance of 1-year-old fish in the catch.

## A. General

## A.1. Stock definition

Sprat in ICES area VIId, VIIe,f.

## A.2. Fishery

Vessels from UK (England and Wales) are responsible for the vast majority of the catches. The majority of the catches are taken in the $3^{\text {rd }}$ and 4th quarter.

The landings in this area are very small and have never been above $6,000 \mathrm{t}$ since 1985 . Since 2000 the landings have been stable around $1,500 \mathrm{t}$.

## A.3. Ecosystem aspects

## B. Data

## B.1. Commercial catch

The commercial catch is provided by the national laboratories belonging to nations exploiting the sprat in the Division VIId and VIIe,f. The sampling intensity for biological samples, i.e., age and weight-at-age has not been performed since 1999, but as the fishery is so small, this is not considered to be a problem.

## B.2. Biological

## B.3. Surveys

There are no surveys targeting sprat in this area.

ANNEX: Sprat IIIa

Stock specific documentation of standard assessment procedures used by ICES.

Stock: Sprat in Division IIIa<br>Working Group: Herring Assessment Working Group (HAWG)<br>Date:<br>16th March 2004

## A. General

A.1. Stock definition

Sprat in ICES area IIIa

## A.2. Fishery

Fleets from Denmark, Norway and Sweden carry out the sprat fishery in Division IIIa. The Danish sprat fishery consists of trawlers using a $16 \mathrm{~mm}-m e s h$ size codend and all landings are used for fishmeal and oil production. Some of the sprat landings from Denmark and Sweden are by-catches in the herring fishery using 32 mm mesh-size cod ends. The Swedish fishery is directed at sprat with by-catches of herring but also includes a fishery carried out with small purse seiners at the West Coast of Sweden for human consumption. The Norwegian sprat fishery in Division IIIa is an inshore purse seine fishery for human consumption.

The majority of the landings are made by the Danish fleet. In 1997 a mixed-clupeoid fishery management regime was changed to a new agreement between the EU and Norway that resulted in a TAC for sprat as well as a by-catch ceiling for herring. Catches are taken in all quarters, though with the bulk of catches in the first and fourth quarter. Denmark has a total ban on the sprat fishery in Division IIIa from May to September.

There was a considerable increase in landings from about $10,000 \mathrm{t}$ in 1993 to a peak of $96,000 \mathrm{t}$ in 1994. From 1996 the landings has been stabilising around $20,000 \mathrm{t}$.

## A.3. Ecosystem aspects

## B. Data

## B.1. Commercial catch

The commercial catch is provided by the national laboratories belonging to nations exploiting the sprat in Division IIIa. The sampling intensity for biological samples, i.e., age and weight-at-age is mainly performed following the EU regulation $1639 / 2001$ as Denmark landing most of the catches follows this regulation. This provision requires 1 sample per 2000 tonnes landed.

The majority of commercial catch and sampling data are submitted in the Exchange sheet v. 1.6.4 and further processed with the SALLOCL-application (Patterson 1998). This program gives outputs on sampling status and available biological parameters and documents actions taken to raise unsampled metiers using other data sets. The species co-ordinator allocates samples of catch numbers, mean length and mean weight-at-age to unsampled catches using appropriate samples by gear
(fleet) area quarter and if an exact match is not available then a neighbouring area if the fishery extends to this area in the same quarter.

## B.2. Biological

Mean weights-at-age (g) in the catches have been very variable over time, but whether this is due to actual variation in mean weight or difficulties in ageing of sprat is uncertain.

No estimation of natural mortality is made for this stock.

## B.3. Surveys

Acoustic estimates of sprat have been available from the ICES co-ordinated Herring Acoustic surveys since 1996. The estimated biomass of sprat has been very variable with low values in the period from 1997 to 2002, but recently the biomass has increased. The majority of the biomass during the acoustic survey is recorded in the Kattegat area.

The IBTS (February) sprat indices (no per hour) in Division IIIa are used as an index of abundance, however, the index has not been considered useful for management of sprat in Division IIIa. The indices are calculated as mean no./hr (CPUE) weighted by area where water depths are between 10 and 150 m (ICES 1995/Assess:13). The indices were revised in 2002 (ICES 2002/ACFM:12) based on an agreement in the IBTS WG in 1999, where it was decided to calculate the sprat index as an area weighted mean over means by rectangles for the IIIa (ICES 1999/D:2). The old time-series of IBTS indices (from 1984-2001) is shown in ICES 2001/ACFM:10.

## TECHNICAL MINUTES

# Herring Assessment Working Group (HAWG) 

Vigo, 3 May 2004

Present:
Reviewers: Carmela Porteiro, Spain, (Chair)
Andre Forest, France
Chair HAWG: Else Torstensen, Norway
Observers:
Jose Maria Bellido (IEO, Spain)
M. Begoña Santos (IEO, Spain)

## 1. General

The reviewers would like to acknowledge the effort made by the WG in compiling all the information and particularly to Else Torstensen for her excellent presentations on the different stocks.

New templates of the Summary Sheets have been introduced this year and some time was devoted to go through all the new headings that are now requested.

All together 12 stocks are considered; this year full analytical assessment has been carried out only for 4 stocks. For the rest, the assessment has either been updated or is experimental.

The new system of sampling requirements implemented by the EU has not been fulfilled for all stocks. The reviewers believe that perhaps sampling should be divided across areas and across seasons not be only an agreed amount per $1,000 \mathrm{t}$.

### 1.1 North Sea Autumn Spawners (NSAS)

The assessment was accepted as a good assessment (similar to last year).
The differences between official landings and the information provided by WG members (official figures are consistently lower across all years) were noted. Landings have been well above the TAC. The fact that misreporting is still substantial and has increased from last year (i.e. catch area misreproted) was also noted. The reviewers believe that discarding could be a problem historically for this stock (in 2002 observers on board mackerel vessels in the Shetland Orkney area noted large discards of herring due probably to the fact that, at the time, the herring quota had already been fished so they continued fishing for mackerel). This year the mackerel quota has decreased and the herring quota is higher so discarding is not expected to be a problem.

The reviewers appreciated the effort that had gone into updating landings and recalculating catches for the period 1995-2002, based on the information that the Norwegian landings are now assumed to be taken in the North Sea and not in IIIa (this has potential effects on the mean weight at age, since fish landed from the North Sea are larger than those from IIIa).

The reviewers point out that landings abroad should be covered by the respective countries to be sure that biological data is collected.

The changes in maturity of the 2-and 3- ringers between last year and this year were noted (last year maturity was extremely high and this year it has averaged $40 \%$ for 2 -ringers, which is the lowest maturity for the whole period). The mean weight at age has also decreased and the reviewers suggested this could be related to a density-dependence effect.

The reviewers note that there is a sign of two poor year classes coming in after a period of good recruitment, although SSB is well above the precautionary biomass and F has stabilised over the last few years.

The reviewers appreciated the use of the new MFST (Multi Fleet Short Term) model and its further development in 2004 to be able to take into account changes in growth and maturity (2004 appears to be well in line with 2003, once corrected for the low maturity of this year which could not have been foreseen).

### 1.2 Downs herring (IVc and VIId)

The reviewers noted the lack of data available for this stock and the need for more historical information. Downs herring has shown independent trends in exploitation rate and recruitment but its current state is unknown. It is separated from North Sea herring by the size of juvenile fish from the larval survey (up 11 mm is considered Downs
herring, smaller than 10 mm is North Sea herring). Downs herring spawns in the Channel and it is mainly taken by Dutch and German fleets on the spawning grounds.

It is a political stock component; it is important at least in some areas although its importance has been much larger in previous years than it is now.

## Western Baltic Spring Spawners (WBSS)

The assessment for this stock is accepted (same as last year).
The reviewers highlighted the need for a specific TAC to be set for the Western Baltic stock and noted that a separate management regime for WBSS in Division IIIa and Subdivision 22-24, should be considered with some urgency.

The reviewers noted the lack of survey coverage of the whole stock at the same time, also the problem that juvenile herring from the North Sea stock has a feeding area in the Skagerrak and Kattegat.

It was noted that the relationships between the recruitment indices have improved although there is still some noise.

For the mean weights-at-age in catches (except for 1-ringers they are all below historical values), the reviewers would like to know (since there are differences between mean weight at age between fish from the Kattegat and Skagerrak) why are they merged in the assessment.

The reviewers noted the reduction in mean F, although its value is probably still high compared with other herring stocks. They also noted the reduction in stock size and SSB from 2002-2003 although it is not considered to be a dramatic change. The recruitment (age 0) improved in 2003 in relation to 2002.

## Celtic Sea and Division VIIj herring

The stock is problematic, the assessment was not accepted last year or the previous year.
The new system of sampling requirements implemented by the EU has not been fulfilled for the Celtic Sea herring, of which very few samples have been analysed. The reviewers note that the ICA model does not fit well in this case (changes in the exploitation pattern, migration, conflicting information, few data for tuning, mixture of spring and autumn spawners, etc.).

From the age composition in the survey and commercial catches (there are differences between both), it seems the fishing pattern has changed towards older fish.

The reviewers hope the data from BTS UK-1q will be made available to the assessment group soon.
Maturity at age (is assumed to be) very different from North Sea stock.

## VIa North

Assessment was accepted last year. State of the stock: uncertain but it is likely lightly exploited.
The reviewers note that, since Scotland introduced a new fishery regulation in 1997, area misreporting has been reduced. The quality of the discard information has also improved and discards are not perceived to be a problem.

Independent strong year classes from the ones in the North Sea. Mean F has been decreasing and in the last 3 years has been relatively stable (little below 0.2). However, even with low level of F the stock has not increased.

Suggestion of reference points last year, but not accepted by ACFM. It is raised again this year. The reviewers note that the presented value for $\mathrm{F}_{\mathrm{lim}}$ of 0.75 is high compared to other herring stocks but that this value is presented more as the result of an exercise than a final proposal. When the review group revised the Summary Sheet for Herring in VIaN, it was clarified that the WG suggest a reference point for $\mathrm{B}_{\lim }$ of $50,000 \mathrm{t}$ and for $\mathrm{B}_{\mathrm{pa}}$ of $75,000 \mathrm{t}$. The reviewers also asked why the longer time series wasn't used to calculate the new reference points and it was indicated to them that lack of time and appropriate tools had prevented it.

## Herring in Divisions VIa (South) and VIIb,c

The state of the stock unknown with respect to biological limits.
In the absence of tuning data, the assessments have been carried out by assuming various terminal F values on the catch-at-age data. Tuning indices are necessary to gain precision in estimates.

The reviewers note that misreporting decreased in recent years $(<1000 \mathrm{t})$.

## Irish Sea herring (VIIa north)

The assessment for this stock was not accepted by the WG.
The reviewers noted that current F, SSB and number at age are highly uncertain, also the conflicting signals in survey data, the lack of recruitment index and the unknown mixture of stocks in the area. The assessment of this stock should continue to be treated with caution.

The reviewers noted that perhaps the WG should try a combined assessment of the 3 stocks since we could be dealing with metapopulations.

## Sprat in the North Sea (Subarea IV)

## The assessment is regarded as exploratory.

Due to the characteristics of the stock (short-lived species, with the stock dominated by 1-and 2-year olds and with unreliable numbers-at age from surveys and catches), Catch Survey Analysis (CSA) has been used for data exploration. It is a new method, also used last year but still with the problem of the results being sensitive to M (it is assumed and set externally, in this case assumed to be constant across ages $=0.7$ from MSVPA) and $s$ (ratio of the survey catchability of the recruits to the fully recruited, fixed externally $=1$, in absence of any other info) parameters. There are problems in understanding the outcome of the model because is missing a good value for M .

The reviewers noted that although survey coverage has improved from last year, it still does not cover the southern part of IVb and into the Channel (due to navigation restrictions).

The reviewers noted that it should be made clear how the WG arrived at the prediction / projection "the projections suggest that the stock would be relative stable or decrease".

    VERY GOOD (v.g) : all landings which individually are $>10 \%$ of the total were sampled, all Q for which there were landings were sampled $\begin{array}{ll}\text { GOOD }(\mathrm{g}) & : \text { landings that constitute the majority of the catch (adding to approx } 70 \% \text { or more of total) were sampled } \\ \text { POOR }(\mathrm{p}) & \text { : some of the large landings not sampled }\end{array}$

    POOR (p) : some of the large landings not sampled
    (1): unsampled quarters
    (2): large landings with few samples or unsampled. High level of sampling corresponds to 1 sample per 100 t landed (WG rep 1997)
    (3): Comment from WG rep. From 1990 going back, Report landings and sampling levels are shown aggregated for the whole year. UK landings lumped in one figure.
    (4): no information in the WGrep of level of sampling prior to 1988. Sampling levels believed to be good. Actual figures to be provided by R. Nash, M Armstrong and CEFAS after going back to their
    (5): NO samples for NI landings in 4th Q , there is a suspicion that the figures correspond to 'paper landings'.
    ${ }^{1}$ Samples applied to NI landings: ${ }^{2}$ Large unsampled landings.
