## 4 Herring (Clupea harengus) in subareas 1, 2, and 5, and in divisions 4.a and 14.a, (Northeast Atlantic) (Norwegian Spring Spawning)

### 4.1 ICES advice in 2017

ICES noted that the stock is declining and estimated to be below MSY $B_{\text {trigger }}$ ( 5 million tonnes) in 2017. Since 1998 four large year classes have been produced (1998, 1999, 2002, and 2004). All year classes since 2005 are estimated to be average or small. Fishing mortality has had an overall declining trend since 2010 and was well below Fmsy in 2016.

A long-term management plan agreed by the EU, Faroe Islands, Iceland, Norway and Russia, is operational since 1999. ICES evaluated the plan and concludes that it is in accordance with the precautionary approach. The management plan implies maximum catches of 384197 t in 2018.

### 4.2 The fishery in 2017

### 4.2.1 Description and development of the fisheries

The distribution of the 2017 Norwegian spring-spawning herring (NSSH) fishery for all countries by ICES rectangles per year is shown in Figure 4.2.1.1 and for annual quarter in Figure 4.2.1.2. The 2017 herring fishing pattern was fairly similar to recent years. The fishery began in January on the Norwegian shelf and focused on overwintering, prespawning, spawning and post-spawning fish (Figure 4.2.1.2 quarter 1). In the second quarter, the fishery was insignificant (Figure 4.2.1.2 quarter 2, $0.5 \%$ of total catch). In summer, the fishery had moved into Faroese, Icelandic and Greenlandic waters (Figure 4.2.1.2 quarter 3). In autumn, the fishery had shifted to the overwintering area in the fjords and oceanic areas north of Tromsø and the central part of the Norwegian Sea. In particular, the catches in the international part of the Norwegian Sea were high (Figure 4.2.1.2 quarter 4). The landings in the $1^{\text {st }}$ quarter constituted $22 \%$ of the total landings and the largest proportion of the landings were in the $4^{\text {th }}$ quarter ( $69 \%$ ) which is an increase from 2016, when $52 \%$ of the landings were registered in the $4^{\text {th }}$ quarter.

### 4.3 Stock Description and management units

### 4.3.1 Stock description

A description of the stock is given in the Stock Annex.

### 4.3.2 Changes in migration

Generally, it is not clear what drives the variability in migration of the stock, but the biomass and production of zooplankton are likely factors, as well as feeding competition with other pelagic fish species (e.g. mackerel) and oceanographic conditions (e.g. limitations due to cold areas). Beside environmental factors, the age distribution in the stock will also influence the migration. Changes in migration pattern of NSSH, as well as of other herring stocks, are often linked to large year classes entering the stock initiating a different migration pattern, which subsequent year classes will follow. No large year classes have entered the stock since 2004, although the 2013 year class is estimated to be above average (since 1988) and was in 2018 observed feeding in the north-eastern part of the Norwegian Sea in May and July. In 2017/2018 there was a shift in wintering
areas. While wintering has been observed in fjords west of Tromsø (Norway) for several years, the 2013 year class wintered in fjords farther north (Kvænangen) in 2017/2018 while the older fish seemed to have had an oceanic wintering area. The oldest and largest fish move farthest south and west during feeding, and the older year classes were in May and July 2018 concentrated in the southwestern areas during the feeding season.

### 4.4 Input data

### 4.4.1 Catch data

Catches in tonnes by ICES division, ICES rectangle and quarter in 2017 were available from Denmark, Faroe Islands, Germany, Greenland, Iceland, Ireland, The Netherlands, Norway, Russia, the UK (Scotland), Poland and Sweden. The total working group catch in 2016 was 721566 tonnes (Table 4.4.1.1) compared to the ICES-recommended catch of maximum 437364 tonnes. The majority of the catches ( $91 \%$ ) were taken in area 2.a as in previous years. Samples were not provided by Greenland, the UK or Poland ( $2.5 \%$ of the total catch were taken by these countries). Sampled catches accounted for $95 \%$ of the total catches, which on a similar level assign previous years. The sampling levels of catches in 2017 in total, by country and by ICES division is shown in Table 4.4.1.2, 4.4.1.3 and 4.4.1.4. Catch by nation, ICES division and quarter are shown in Table 4.4.1.5. The software SALLOC (ICES, 1998) was used to calculate total catches in numbers-at-age and mean weight at age representing the total catch. Samples allocated (termed fill-in in SALLOC) to cells (nation, ICES division and quarter) without sampling information are shown in Table 4.4.1.5.

### 4.4.2 Discards

In 2008, the Working Group noted that in this fishery an unaccounted mortality caused by fishing operations and underreporting probably exists (ICES, 2008). It has not been possible to assess the magnitude of these extra removals from the stock, and considering the large catches taken after the recovery of the stock, the relative importance of such additional mortality is probably low. Therefore, no extra mortality to account for these factors has been added since 1994. In previous years, when the stock and the quotas were much smaller, an estimated amount of fish was added to the catches.

The Working Group has not had access to comprehensive data to estimate discards of the herring. Although discarding may occur on this stock, it is considered to be low and a minor problem to the assessment. This is confirmed by estimates from sampling programmes carried out by some EU countries in the Data Collection Framework. Estimates on discarding in 2008 and 2009 of about $2 \%$ in weight were provided for the trawl fishery carried out by the Netherlands. In 2010 and 2012, this métier was sampled by Germany. No discarding of herring was observed ( $0 \%$ ) in either of the two years. An investigation on fisheries induced mortality carried out by IMR with EU partners on fisheries induced and unreported mortality in mackerel and herring fisheries in the North Sea concluded with an estimated level of discarding at around 3\%.

In order to provide information on unaccounted mortality caused by fishing operations in the Norwegian fishery, Ipsos Public Affairs, in cooperation with IMR and the fishing industry, conducted a survey in January/February 2016. The survey was done by phoning skippers and interviewing them. A total of 146 herring skippers participated in the survey, 31 skippers representing the bigger vessel group and 115 skippers representing the smaller vessel group. The data provided an indication that there have been periods
of increased occurrence of net bursting. This was seen especially in the period 20072010. There was, however, no trend in the size of catches where bursting has occurred.

When it comes to slipping, the data showed a steady increase in the percentage that has slipped herring from 2004-2012, and then a significant decline in recent years. The variations in the proportion that have slipped herring were largely driven by the skippers on smaller coastal purse-seiners. Average size of purse-seine hauls slipped seems to be relatively steady over the period. However, the average size of net hauls slipped was lowest in the recent period. An attempt to estimate the level of slipping/bursting (in tonnes) based on these data is planned.

### 4.4.3 Age composition of the catch

The estimated catch-at-age in numbers by years are shown in Table 4.4.3.1. The numbers are calculated using the SALLOC software. In 2017, about $14 \%$ of the catches (in numbers) were taken from both the 2009 year class and the 2013 year class, followed by the 2006 ( $13 \%$ ) and 2011 ( $12 \%$ ) year classes. The 2004 year class still contributes, with $10 \%$ of the catches in 2017.

Catch curves were made on the basis of the international catch-at-age (Figure 4.4.3.1). For comparison, lines corresponding to $\mathrm{Z}=0.3$ are drawn in the background. The big year classes, in the periods of relatively constant effort, show a consistent decline in catch number by cohort, indicating a reasonably good quality of the catch-at-age data. Catch curves for year classes 2005 onwards show a more flat curve than for previous year classes indicating a lower F or a changed exploitation pattern.

### 4.4.4 Weight at age in catch and in the stock

The weight-at-age in the catches in 2017was computed from the sampled catches using SALLOC. Trends in weight-at-age in the catch are presented in Figure 4.4.4.1 and Table 4.4.4.1. The mean weights at age for most of the age groups have generally been increasing in 2010-2013 but levelled off in 2014 and seem to have decreased slightly during the most recent years. A similar pattern is observed in weight-at-age in the stock which is presented in Figure 4.4.4.2 and Table 4.4.4.2. These data have been taken from the survey in the wintering area until 2008. The mean weight at age in the stock for age groups $4-11$ in the years 2009-2017 was derived from samples taken in the fishery in the same area and at the same time as the wintering surveys were conducted in.

### 4.4.5 Maturity-at-age

In 2010 the method for estimating maturity-at-age in the stock assessment of NSSH was changed based on work done by the "workshop on estimation of maturity ogive in Norwegian spring-spawning herring" (WKHERMAT; ICES, 2010a). The method which was adopted by WGWIDE in 2010 (ICES, 2010b) is based on work by Engelhard et al. (2003) and Engelhard and Heino (2004). They developed a method to back-calculate age at maturity for individual herring based on scale measurements, and used this to construct maturity ogives for the year classes 1930-1992.

The NSSH has irregular recruitment pattern with a few large year classes dominating in the stock when it is on a high level. Most of the year classes are, however, relatively small and referred to as "normal" year classes. The back calculation dataset indicates that maturation of the large year classes is slower than for "normal" year classes.

WKHERMAT and WGWIDE considered the dataset derived by back calculation as a suitable potential candidate for use in the assessment because it is conceived in a consistent way over the whole period and can meet standards required in a quality controlled process. However, the back calculation estimates cannot be used for recent years since all year classes have to be fully matured before included. Therefore, assumptions have to be made for recent year classes. For recent year classes, WGWIDE (2010) decided to use average back-calculated maturity for "normal" and "big" year classes, respectively and thereby reducing maturity-at-age for ages 4,5 and 6 when strong year classes enter the spawning stock. The default maturity ogives used for "normal" and "big" year classes are given in the text table below.

| AGE | $\mathbf{0}$ | $\mathbf{1}$ | $\mathbf{2}$ | $\mathbf{3}$ | $\mathbf{4}$ | $\mathbf{5}$ | $\mathbf{6}$ | $\mathbf{7}$ | $\mathbf{8}$ | $\mathbf{9}$ | $\mathbf{1 0}$ | 11 | 12 | 13 | 14 | 15 |
| :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- |
| normal <br> ycl | 0 | 0 | 0 | 0 | 0.4 | 0.8 | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1 |
| strong <br> ycl | 0 | 0 | 0 | 0 | 0.1 | 0.6 | 0.9 | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1 |

Assumed values should be replaced by back-calculated values in the annual assessments for each year where updated values are available. This was last done in the benchmark assessment in 2016. Therefore, two years (2012 and 2013) could be updated with back-calculated values in the present assessment. Assumed and updated values are shown in figure 4.4.5.1. The maturity ogives used in the present assessment are presented in Table 4.4.5.1.

### 4.4.6 Natural mortality

In this year's assessment, the natural mortality $\mathrm{M}=0.15$ was used for ages 3 and older and $\mathrm{M}=0.9$ was used for ages $0-2$. These levels of M are in accordance to previous years and their justification is provided in the stock annex. Information about deviations from these levels in the time-series, e.g. due to diseases, are also provided in the stock annex.

### 4.4.7 Survey data

The surveys available for the assessment are described in the stock annex. Only two of the available surveys are used in the final assessment and will therefore be dealt with in this section:

1 ) The International Ecosystem Survey in the Nordic Seas (IESNS) in May. The survey covers the entire stock during its migration on the feeding grounds, the adults in the Norwegian Sea and adjacent waters ("Fleet 5") and the juveniles in the Barents Sea ("Fleet 4").

2 ) The Norwegian acoustic survey on the spawning grounds ("Fleet 1") in February.

The cruise reports from the IESNS and spawning survey in 2018 are available as working documents to this report. Both surveys were successfully conducted in 2018.

The abundance estimates from "Fleet 1" are shown in Table 4.4.7.1 and Figure 4.4.7.2; from "Fleet 4" in Table 4.4.7.2 and Figure 4.4.7.1 and "Fleet 5" in Table 4.4.7.3and Figure 4.4.7.1.

Catch curves were made on the basis of the abundance estimates from the surveys "Fleet 1" (Figure 4.4.7.3) and "Fleet 5" (Figure 4.4.7.4). The same arguments are valid for the interpretation of the catch curves from the surveys as from the catches. In 2010,
the number of all age groups decreased suddenly in "Fleet 5" and this is seen as a drop in the catch curves that year. This drop has continued for some of the year classes and the year classes 1998 and 1999 are disappearing faster from the stock than expected. This observed fast reduction in these age classes may also be influenced by the changes in "Fleet 5" catchability, with seemingly higher catchability in years 2006-2009. Like the catch curves from commercial landings, the corresponding curves from "Fleet 5" are also quite flat for year classes 2005 onwards. As "Fleet 1" was not conducted in the years 2009-2014, there is a gap in the catch curves, making it difficult to interpret them.

### 4.4.8 Sampling error in catches and surveys

Sampling errors for Norwegian catch-at-age for the years 2010-2017 is estimated using ECA (Salthaug and Aanes 2015, Hirst et al. 2012). Using the Taylor function (Aanes 2016a) to model the sampling variance of the catches yields a very good fit ( $R_{a d j}^{2}=$ 0.94 ) and using this function to impute missing sampling variances for catch-at-age yields relative standard errors shown in Table 4.4.8.1. It is assumed that the relative standard errors in the total catches are equal to the Norwegian catches (which comprise $\sim 60 \%$ of the total catches). Sampling errors for survey indices are estimated using StoX (http://www.imr.no/forskning/prosjekter/stox/nb-no). For Fleet 1 estimates are available for the years 1988-1989, 1994-1996, 1998-2000, 2005-2008, and 2015-2018, for Fleet 4 estimates of sampling errors are available for 2009-2018, and for Fleet 5 for 20082018. Missing values for sampling variances are imputed using the Taylor function which provides goods fits ( $R_{a d j}^{2}$ 's are $0.94,0.98,0.96$, respectively). The resultant relative standard errors are given in Tables 4.4.8.2-4.4.8.4. Due to the very good fits of the Taylor functions, estimates of relative standard where empirical estimates are available, are also replaced by the model predicted values to reduce potential effects of imprecise estimates of errors.

### 4.4.9 Information from the fishing industry

No information is made available for the working group.

### 4.5 Stock assessment

The first benchmark of the NSSH took place in 2008. The assessment tool TASACS was then chosen to be the standard assessment tool for the stock. The second benchmark took place in 2016 (ICES 2016c) where three assessment models were explored, TASACS, XSAM and one separable model. WKPELA accepted XSAM as the standard assessment tool for the NSSH.

### 4.5.1 XSAM final assessment 2018

The XSAM model is documented in Aanes 2016a and 2016b. XSAM includes the option to utilize the prediction of total catch in the assessment year (typically sum of national quotas) along with the precision of the prediction. This was changed in 2017 as it was found that the model estimated a highly variable and significantly lower compared to the working group's prediction (sum of national quotas). In addition, this caused an abrupt change in the selection pattern from 2017 and onwards. The abrupt change in the selection pattern was not fully understood by the working group, but the effect was less pronounced if not using the catch prediction from the model for 2017. Therefore, it was decided to not utilize the prediction of total catches in 2017 when fitting the model to data (i.e. the assessment) and consequently in the short-term forecast. The same approach is taken in the 2018 assessment, i.e. the catch prediction for 2018 is not included when fitting the model to data. The resulting estimated selection pattern is
gradual (Figure 4.5.1.1) and in line with the current knowledge about the fishery. It is important to notice that this has marginal effect on the assessment, but larger effects on the prediction and short-term forecast.

This year's XSAM assessment was performed with the same model options as in 2017. In summary this means that the model was fitted with time varying selectivity and effort according to $\operatorname{AR}(1)$ models in the model for fishing mortality; the recruitment was modelled as a process with constant mean and variance; the standard errors for all input data were predetermined using sample data (Tables 4.4.8.1-4.4.8.4), but estimating a scaling constant common for all input data to allow additional variability in the input data that is not controlled by sampling. Other details in settings are given in the Stock Annex.

The same input data over the same age ranges was used as in 2017. At the 2016 benchmark, data from 1988 and onwards was used, the considered age-span was 3-12+ with input data catch-at-age, Fleet 1 and Fleet 5 and in WGWIDE 2016 it was decided to start the model at age 2 to enable short-term predictions with reasonable levels of variability. To achieve this, age 2 from Fleet 4, and age 2 in catch-at-age is included in input data. Evaluation of diagnostics including lower ages than 2 and/or other fleets resulted in excluding lower ages than 2 and other fleets for the final assessment. Input data are listed in Table C.1.1 in the Stock Annex.

The parameter estimates are shown in Table 4.5.1.1. For a precise definition of the parameters it is referred to Aanes 2016a in ICES (2016). Note that the variance components $\sigma_{1}^{2}$ (variability in the separable model for F ) and $\sigma_{R}^{2}$ (variability in recruitment) is rather imprecise. The estimate of the scaling constant $h$ is larger than 1 showing that the model adds additional variability on the observation errors than explained by the sampling errors alone.

The catchabilities for all the fleets are on average positively correlated indicating some uncertainty due to a common scaling of all surveys to the total abundances although the correlations in general are small (Figure 4.5.1.2). There is a slight negative correlation between $\sigma_{1}^{2}$ and $\sigma_{2}^{2}$ (variability in the AR process for time varying selectivity) indicating little contrast in data for separating variability in the separable model from variability due to changes in selection pattern. The slopes in the multivariate AR model for time-varying selectivity gradually changes from negative to positive, but is expected as it is imposed due to the sum to zero constraint for the selection (see Aanes 2016a for details).

The weights each datum is given in the model fit (inverse of the sampling variance) is proportional to the empirical weights derived from sampling variances (Tables 4.4.8.14.4.8.4) which shows that the strong year classes in general is given larger weight to the model than weak year classes, and the ordering of the average weights (from high to low) is Catch-at-age, Fleet 5, Fleet 1 and Fleet 4 (Figure 4.5.1.3).

Two types of residuals are considered for this model. The first type is the model prediction (based on all data) vs. the data. In such time-series models, the residuals based on the prediction which uses all data points will be serially correlated although useful as they explain the unexplained part of the model (cf Harvey 1990 p 258).This means that patterns in residuals over time is to be expected and questions the use of e.g. qqplots as an additional diagnostic tools to assess distributional assumptions. To obtain residuals which follow the assumptions about the data in the observation models (e.g. serially uncorrelated) single joint sample residuals are extracted (ICES 2017). In short these are obtained by sampling predicted values from the conditional distribution of
values given the observations. This sample corresponds to a sample from the joint distribution of latent variables and observations. The third approach could have been to extract the one step ahead observation residuals which are standard for diagnostics for regular state-space models (cf Harvey 1990). This is not done here.
The negative residuals tracing the 1983 year class for catch-at-age represents low fishing mortalities examining the type 1 residuals (Figure 4.5.1.4). This effect is less pronounced considering the type 2 residuals. The type 2 residuals are qualitatively comparable with the type 1 residuals but generally display more mixed residuals as predicted by the theory. Otherwise the residuals for catch-at-age appears fairly mixed apart for some serial correlation for age 2 and 3 (which are very low), and some negative residuals for the plus group the most recent years. The residuals for Fleet 1 in 1994 and 2015 for young and old ages are all of the same signs and may appear as year effects. Also note that the residuals for Fleet 1 for ages $10+$ in 2015 and 2016 are all positive (Figure 4.5.1.4) which shows that the abundance indices from Fleet 1 displays a larger stock size over these ages and years compared to the assessment using all input data. However, these data points are given low weights (Figure 4.5.1.3) as they are found imprecise (Tables 4.4.8.1-4.4.8.4). Some serial correlation for residuals for ages 3 and 4 in Fleet 1 can also be detected, but is down weighted by the same reasons. Serial correlation in residuals for age 2 in Fleet 4 can also be detected indicating trends over time in mismatch between estimates and observations of abundance at age 2. Residuals for Fleet 5 appears adequate compared to previous years although some serial correlations can be detected also here.

The residuals for small values are bigger than residuals for the larger values since smaller values in general have higher variances than larger values (Tables 4.4.8.14.4.8.4) (Figure 4.5.1.5).The qq-plots for the standardized residuals show that the distributional assumptions on the observation errors are adequate, except for the smallest and largest values of catch-at-age and indices from Fleet 1. As qq-plots for residuals of type 1 may be questioned (see above) it is noted that qq-plots for residuals of type 2 is more relevant and generally shows a significantly better fit based on a visual inspection compared to using type 1 .

The marginal likelihood and the components for each data source (see Aanes 2016b for details) are profiled over a range of the common scaling factor $h$ for all input data (Figure 4.5.1.6). It is apparent that the optimum of the marginal likelihood is clearly defined. The catch component is decreasing with decreasing values of $h$ indicating that the model puts more weight on the catch component than indicated by the comparing sampling errors for all input data. This is in line with the findings in Aanes (2016a and 2016b) who showed that these types of models tends to put too much weight on the catch data if the weighting is not constrained. However, the likelihood component for the catch is overruled by the information in Fleet 1, 4 and 5 such that the optimum for the marginal likelihood is clearly defined. The point estimates of SSB and F is insensitive to different values of $h$.

The retrospective runs for this model shows estimates which is within the estimated levels of precision (Figure 4.5.1.7). The indices from Fleet 1 indicate, on average, a relatively larger abundance than the indices from Fleet 5 for 2015-2017 which is supported by the positive residuals for ages $9-10+$ (Figure 4.5.1.4). Consequently, the increased estimates of SSB and decreased estimates of F after 2014 is a response to the indices from Fleet 1 which not was conducted in the years 2009-2014. Note that the retrospective estimates are remarkably stable from 2015 and onwards. To illustrate the conflict in data and increased uncertainty in estimates the most recent years, the abundance
indices are scaled to the absolute abundance by the estimated catchabilities. Then the spawning-stock biomass based on each survey index is calculated using the stock weights at age and proportion mature at age (Figure 4.5.1.8). Here we see a fairly good temporal match between the model estimate of SSB and the survey SSBs except for the years 2015 and 2016 for Fleet 1, which display a significantly faster reduction in the stock compared to Fleet 5 which shows a more flat trend in the same years. It is worth noticing that although the point estimate of SSB based on Fleet 1 appear very much higher than Fleet 5 in 2015 and 2016, the uncertainty in the estimates are very high, such that the respective estimates do not appear as significantly different. However, the effect on the final assessment is to lift the point estimate of SSB and increase the uncertainty which is in accordance with the data used (Figure 4.5.1.9).

The final assessment results are shown in Figure 4.5.1.9. The estimates of fishing mortality for 2017 is rather high, as a response to the high catch in 2017 with a point estimate of 0.174 although the estimate is rather imprecise since the $95 \%$ confidence interval ranges from $0.123-0.224$. The spawning stock shows a declining trend since 2009, and the $95 \%$ confidence interval of the stock level in 2018 ranges from $\sim 3.1$ to $\sim 4.6$ million tonnes which barely envelopes $\mathrm{B}_{\mathrm{mp}}=3.184$ million tonnes, such that the probability of the stock being above $\mathrm{B}_{\mathrm{lim}}=2.5$ million tonnes is high. Note the rather large uncertainty in the absolute levels since the peak in 2009 with the further increase in the most recent years. This high uncertainty is a result of the conflicting signals in data concerning the degree of decrease in the stock over this time period.

The final results of the assessment are also presented in Tables 4.5.1.2 (stock in numbers), 4.5.1.3 (fishing mortality) and Table 4.5.1.4 is the summary table of the assessment.

### 4.5.2 Exploratory assessments

### 4.5.2.1 TASACS

TASACS was run according to the benchmark in 2008 using the VPA population model in the TASACS toolbox with the same model options as the benchmark (see Stock Annex). The information used in the TASACS run is catch data and survey data from eight surveys. The analysis was restricted to the years 1988-2018. The model was run with catch data from 1988 to 2017, and projected forwards through 2018 assuming Fs in 2018 equal to those in 2017, to include survey data from 2018. The larval survey (SSB fleet) was discontinued in 2017 and no new information is therefore available from this survey.

The model fit to the tuning data is shown with Q-Q plots in Figure 4.5.2.1.1. Surveys 1, 2,3 and 7 seem to fit rather well to the assumed linear relationship in the TASACS model, but surveys 4,6 and 8 have rather poor fit. Since 2016 the TASACS run Q-Q plots for fleet 5 shows a poorer fit compared to earlier assessments. This is mainly caused by a change in estimated catchability.

Particularly Survey 8 (larval survey) seems to have a poor fit. This can also be seen as a block of positive residuals for this survey in later years (Figure 4.5.2.1.2). The residual plot for survey 5 (IESNS) also shows some pattern with consecutive series of negative and positive residuals indicating year-effects.

The results from TASACS are compared to those from XSAM and TISVPA in Figure 4.5.2.1.3.The time-series of SSB show similar trends for XSAM and TASACS while TISVPA do not show the same downward trend in the later period. For most of the years,
the estimates from TASACS and TISVPA are mostly within the confidence limits estimated by XSAM. The SSB on 1 January 2018 is estimated by TASACS to be 3.693 million tonnes, which is lower than the estimated value from TISVPA but close to the point estimate from XSAM.

### 4.5.2.2 TISVPA

The TISVPA model was applied using the catch-at-age data with range from 0 to $15+$ and data from three surveys (Survey 1, 4 and 5). No data points were down-weighted. Two-parametric selection pattern used in the model revealed some obvious peculiarities in the interaction between the stock and the fishery.
Rather clear signals about the stock biomass in 2018 were obtained from just catch-atage and surveys 1,4 and 5 . Catch-at-age and Survey 1 data, as well as the overall objective function of the model, indicate the SSB value in 2018 about 4.7 million tonnes (see WD 12). Surveys 4 and 5 indicate the SSB value about 6 and 4 million tonnes respectively.
The results from TISVPA are compared to those from XSAM and TASACS in Figure 4.5.2.1.3.

### 4.6 NSSH reference points

ICES last reviewed the reference points of Norwegian spring spawning herring in April 2018. ICES concluded that Blim should remain unchanged at 2.5 million tonnes and MSYB trigger $=B_{\text {pa }}$ was estimated at 3.184 million tonnes. FMSY was estimated at 0.102 , but during an ongoing work on Management Strategy Evaluation Fmsy has been revisited, because issues were found with numerical instability and settings when $\mathrm{F}_{\text {MSY }}=0.102$ was set. Therefore Fmsy is currently being re-estimated.

### 4.6.1 PA reference points

The PA reference points for the stock were last estimated by WKNSSHREF in 2018. The
 3.184 million tonnes and $\mathrm{F}_{\mathrm{pa}}=0.182$. $\mathrm{F}_{\mathrm{pa}}$ is presently being revisited in WKNSSHMSE.

### 4.6.2 MSY reference points

The MSY reference points were evaluated by WKNSSHREF in 2018. In the ICES MSY framework Bpa is proposed/adopted as the default trigger biomass Btrigger and was estimated at 3.184 million tonnes. Fmsy is currently being revisited by WKNSSHMSE.

### 4.6.3 Management reference points

In the current management plan the Coastal States have agreed a target reference point defined at $F_{\text {target }}=0.125$ when the stock is above $B_{p a}$. If the $S S B$ is below $B_{p a}$, a linear reduction in the fishing mortality rate will be applied from 0.125 at $\mathrm{B}_{\mathrm{pa}}$ to 0.05 at $\mathrm{Blim}_{\text {. }}$

There is ongoing work (WKNSSHMSE) to answer a request from the Coastal States on updated Management Strategy.

### 4.7 State of the stock

The SSB on 1 January 2018 is estimated by XSAM to be 3.826 million tonnes which is above $B_{p a}(3.184$ million $t)$. The stock is declining and the SSB time-series from the 2018 assessment is in line with the SSB time-series from the 2017 assessment. In the last 15 years, five large year classes have been produced (1998, 1999, 2002, 2003, and 2004). The 2005 to 2015 year classes are estimated to be average or small, however, the 2016 year class is estimated to be well above average (from 1988). Fishing mortality in 2017 is estimated to be 0.174 which is above the management plan $F$ that was used to give advice for 2017. A new management plan is being developed for the 2019 advisory year.

### 4.8 NSSH Catch predictions for 2018

### 4.8.1 Input data for the forecast

Forecasting was conducted using XSAM according to the method described in the Stock Annex and by Aanes (2016c). WGWIDE 2016 decided to use the point estimates from this forecast as basis for the advice. In short the forecast is made by applying the point estimates of the stock status as input to set TAC, then based on the TAC a stochastic forecast were performed to determine levels of precision in the forecast. Table 4.8.1.1 list the point estimates of the starting values for the forecast. The input stock numbers-at-age 2 and older were taken from the final assessment. The catch weight-at-age, used in the forecast, is the average of the observed catch weights over the last 3 years (2015-2017).
For the weight-at-age in the stock, the values for 2018 were obtained from the commercial fisheries in the wintering areas in January. For the years 2019 and 2020 the average of the last 3 years (2016-2018) was used.

Standard values for natural mortality were used. Maturity-at-age was based on the information presented in Section 4.4.5.

The exploitation pattern used in the forecast is taken from the predictions made by the model (see Aanes 2016c for details). The resultant mean annual exploitation pattern is shown in Figure 4.8.1.1 and displays a shift towards older fish in the recent years and further in the prediction. Prediction of recruitment at age 2 is obtained by the model with a mean that in practice represents the long term (1988-2018) estimated mean recruitment (back-transformed mean at log scale) and variance the corresponding recruitment variability over the period. Forecasted values of recruits are highly imprecise but have little influence on the short-term forecast of SSB as the herring starts to mature at age 4 .

The average fishing mortality defined as the average over the ages 5 to 12 is weighted over the population numbers in the relevant year

$$
\bar{F}_{y}=\sum_{a=5}^{12} N_{a, y} F_{a, y} / \sum_{a=5}^{12} N_{a, y}
$$

where $F_{a, y}$ and $N_{a, y}$ are fishing mortalities and numbers by age and year. This procedure is in accordance with previous years for this stock but the age range is shifted from 5-11 to 5-12.

There was no agreement of a TAC for 2018. To obtain an estimate of the total catch to be used as input for the catch-constraint projections for 2019 , the sum of the unilateral
quotas was used. In total, the expected outtake from the stock in 2018 amounts to 546 448 tonnes. F in 2018 is estimated by XSAM based on this catch.

### 4.8.2 Results of the forecast

The Management Options Table with the results of the forecast is presented in Table 4.8.2.1. Assuming a total catch of 546448 tonnes is taken in 2018, it is expected that the SSB will increase from 3.826 million tonnes ( $95 \%$ confidence interval 3.065 to 4.587 million tonnes) on 1 January in 2018 to 3.859 million tonnes in 2019 ( $95 \%$ confidence interval 3.069 to 4.866 million tonnes). The $95 \%$ confidence interval for weighted $F$ over ages $5-11$ in 2018 ranges from 0.03 to 0.275 with a mean of 0.117 , while the corresponding values for ages 5-12 are $0.035,0.280$ and 0.125 , respectively.

### 4.9 Comparison with previous assessment

A comparison between the assessments 2008-2017 is shown in Figure 4.9.1. In the years 2008 - 2015 the assessments were made with TASACS, whereas since 2016 XSAM has been applied, as accepted by WKPELA 2016. With the change of the assessment tool in 2016 the age of the recruitment changed from 0 to 2 and the age span in the reference F changed from $5-14$ to $5-11$. In WKNSSHREF (2018) this was further changed to 5-12.

The table below shows the SSB (thousand tonnes) on 1 January in 2017 and weighted F in 2016 as estimated in 2017 and 2018.

|  | ICES 2017 |  | WG 2018 | \%DIFFERENCE |
| :--- | ---: | :--- | :--- | :--- |
| SSB(2017) | 4131 | 4235 | $2.5 \%$ |  |
| Weighted F $(2016)^{*}$ | 0.084 | 0.092 |  |  |

*F in the 2017 assessment was based on the age span 5-11 and therefore not directly comparable to the F in the 2018 assessment which was based on the age span 5-12.

### 4.10 Management plans and evaluations

The long-term management plan of Norwegian spring spawning herring aims for exploitation at a target fishing mortality below $\mathrm{F}_{\mathrm{pa}}$ and is considered by ICES in accordance with the precautionary approach (WKBWNSSH, ICES, 2013d). The management plan in use contains the following elements:

Every effort shall be made to maintain a level of Spawning-stock biomass (SSB) greater than the critical level ( $\mathrm{Blim}_{\mathrm{lim}}$ ) of 2500000 t .

For 2012 and subsequent years, the Parties agreed to restrict their fishing on the basis of a TAC consistent with a fishing mortality rate of less than 0.125 for appropriate age groups as defined by ICES, unless future scientific advice requires modification of this fishing mortality rate.

Should the SSB fall below a reference point of $5000000 t\left(\mathrm{~B}_{\mathrm{pa}}\right)$, the fishing mortality rate, referred under Paragraph 2, shall be adapted in the light of scientific estimates of the conditions then prevailing to ensure a safe and rapid recovery of the SSB to a level in excess of 5000000 t . The basis for such adaptation should be at least a linear reduction in the fishing mortality rate from 0.125 at $B_{p a}(5000000 t)$ to 0.05 at $B_{\lim }(2500000 t)$.

The Parties shall, as appropriate, review and revise these management measures and strategies on the basis of any new advice provided by ICES.

A brief history of it is in the stock annex. In general, the stock has been managed in compliance with the management plan.

There is ongoing work to answer a request from the Coastal States on updated Management Strategy, which will be based on the new MSY reference points.

### 4.11 Management considerations

Perception of the stock has not changed since last year's assessment (estimated SSB in 2017 is $2.5 \%$ higher in this year's assessment). Results of exploratory runs by other models match with those of XSAM.
Historically, the size of the stock has shown large variations and dependency on the irregular occurrence of very strong year classes. Between 1998 and 2004 the stock produced several strong year classes which lead to an increase in SSB until 2009. Since then, SSB has declined due to absence of strong year classes after 2004, but the 2016 year class is estimated to be above average (since 1988).
Since 1999 catches have been regulated through an agreed management plan, which is considered to be precautionary. However, since 2013, a lack of agreement by the Coastal States on their share in the TAC has led to unilaterally set quotas which together are higher than the TAC indicated by the management plan resulting in steeper reduction in the SSB than otherwise.

At present work on management strategy evaluation is ongoing and a new management strategy is expected to be in place for the advisory year 2019.

### 4.12 Ecosystem considerations

NSS herring juveniles and adults are an important part of the ecosystems in the Barents Sea, along the Norwegian coast, in the Norwegian Sea and in adjoining waters. This refers both to predation on zooplankton by herring and herring being a food resource to higher trophic levels (e.g. cod, saithe, seabirds, and marine mammals). The predation intensity of and on herring have seasonal, spatial and temporal variation as a consequence of variation in migration pattern, prey density, stock size, size of year classes and stock sizes of competing stocks for resources and predators. Recent features of some of these ecosystem factors of relevance for the stock are summarized below.

- The stock's more westerly feeding distribution in recent years (ICES 2017a; 2017b) might be due to better feeding opportunities there or a response to feeding competition with mackerel but the consequence is a less spatial overlap of herring and mackerel in Norwegian Sea and adjoining waters since around 2014 (Nøttestad et al., 2014; ICES, 2015b; 2016b; 2017b).
- Where herring and mackerel overlap spatially they compete for food to some extent (Bachiller et al., 2015; Debes et al., 2012; Langøy et al., 2012; Óskarsson et al., 2015) but studies showing mackerel being more effective feeder might indicate that the herring is forced to the western and northern fringe of Norwegian Sea, although higher zooplankton biomass there could also attract the herring (Nøttestad et al., 2014; ICES, 2015b; 2016b).
- Results of stomach analyses of mackerel on the Norwegian coastal shelf (between about $66^{\circ} \mathrm{N}$ and $69^{\circ} \mathrm{N}$ ) suggest that mackerel fed opportunistically on herring larvae, and that predation pressure therefore largely depends on the degree of overlap in time and space (Skaret et al., 2015).
- The 2013 year class of herring is the strongest since the 2004 year class. In the May survey it was found both in the north eastern and in the central part of the Norwegian Sea.
- Herring growth (i.e. length-at-age) varied over the period 1994-2015 and was negatively related to stock size (Homrum et al., 2016), which indicates interaction between fish density and prey availability.
- Following a maximum in zooplankton biomass during the early 2000s the biomass declined with a minimum in 2006. From 2010, the trend turned to an increase and reached the long-term mean in 2014. Zooplankton biomass dropped again in 2015, but has been increasing since then. Interestingly, all the areas, excluding east of Iceland and on few occasions Jan Mayen AF (Figure 6.2), show parallel changes in zooplankton biomass.
- The Subpolar gyre, which has been in a weak state since mid 1990's, has been strengthening during the last three years. If this trend continues, we should expect increased levels of silicate entering the Norwegian Sea over the coming years and consequently a reversal in the declining trend of silicate observed in the Norwegian Sea since 1990. Increasing silicate concentrations are expected to affect growth of silicate demanding phytoplankton, which again will affect zooplankton grazing (ICES, 2018a, and references therein).
- The temperatures of the inflowing Atlantic water were in 2017 above the long-term means (1981-2010) for the whole region. The salinity in the Atlantic Water was below the long-term means in the south and close to or higher than the normal in the north. The heat content increased in the North and Norwegian Seas and it was record-high in the Norwegian Sea. In the Barents Sea the ice cover during 2017 was below the long-term mean during the whole year (ICES, 2018b).

### 4.13 Changes in fishing patterns

The fishery for Norwegian spring spawning herring has generally been described as progressing clockwise in the Nordic Seas as the year progresses. In the recent years (after $\sim 2013$ ) this pattern has changed, because there has been an extended fishery in the south and southwestern areas in the Norwegian Sea in the $3^{\text {rd }}$ and $4^{\text {th }}$ quarters $(8 \%$ and $69 \%$ respectively in 2017), and thus almost $3 / 4$ 's of the herring catch was taken in the last quarter of 2017. The majority of the catches in the $4^{\text {th }}$ quarter are now taken in the central parts of the Norwegian Sea, whereas in the preceding years there was a more significant fishery in northeastern areas (outside northern Norway and southwest of the Bear Island). This change in migration resulted in late arrival at the Norwegian coast for this part of the stock during the winter 2017/2018. The Norwegian coastal fleet (smaller vessel that cannot go that far offshore) could therefore not access this herring during the winter fishery and targeted younger fish (mostly of the 2013 and 2014 year classes) which overwintered in Norwegian fjords.

### 4.14 Recommendation

In the IESNS survey other herring stocks (e.g. Icelandic summer spawning herring and North Sea herring) are found in the boundary regions of the survey area. WGWIDE recommends that WGIPS initiates work to distinguish between herring stocks on the individual level as well as to provide abundance indices by stock.

** mean weight at ages 11 and 13 are mean of 5 previous years at the same age. These age groups were not present in the catches of the wintering survey from which the stock weight are derived.
*** derived from catch data from the wintering area north of $69^{\circ} \mathrm{N}$ during December 2008 - January 2009 for age groups 4-11.
${ }^{* * * *}$ derived from catch data from the wintering area north of $69^{\circ} \mathrm{N}$ during January 2010 for age groups 4-12.

Table 4.4.5.1. Norwegian Spring-spawning herring. Mature at age. The time-series was provided by WKHERMAT in 2010 and are used in the assessment since 2010.

### 4.17 Figures

Figure 4.2.1.1. Total reported landings (ICES estimates) of Norwegian spring-spawning herring in 2017 by ICES rectangle. Landings below 10 tonnes per statistical rectangle are not included. The landings with information on statistical rectangle constitute $\mathbf{9 9 \%}$ of the reported landings.

Figure 4.2.1.2. Total reported landings (ICES estimates) of Norwegian spring-spawning herring in 2017 by quarter and ICES rectangle. Landings below 10 tonnes per statistical rectangle are not included. The landings with information on statistical rectangle constitute $\mathbf{9 9 \%}$ of the reported landings.

Figure 4.4.3.1. Norwegian spring spawning herring. Age disaggregated catch in numbers plotted on $a \log$ scale. Age is on x -axis. The labels indicate year classes and grey lines correspond to $\mathrm{Z}=0.3$.

Figure 4.4.4.1.Norwegian spring spawning herring. Mean weight at age by age groups $3-14$ in the years 1981-2017 in the catch (weight at age for zero catch numbers were omitted)

Figure 4.4.4.2.Norwegian spring-spawning herring. Mean weight at age in the stock 1981-2018.

Figure 4.4.5.1. Assumed (blue line) and updated (orange line) maturity-at-age for the years 2012 and 2013.

Figure 4.4.7.1.Distribution of Norwegian spring-spawning herring as measured during the IESNS survey in April-June 2018 in terms of NASC values ( $\mathrm{m}^{2} / \mathrm{nm}^{2}$ ) for every 1 nautical mile. The stratification of the survey area is shown on the map.

Figure 4.4.7.2. Norwegian acoustic survey on the NSSH spawning grounds. Distribution and acoustic density of herring recorded in 2018.

Figure 4.4.7.3. Norwegian spring spawning herring. Age disaggregated abundance indices (billions) from the acoustic survey on the spawning area in February-March (survey 1) plotted on a log scale. The labels indicate year classes and grey lines correspond to $\mathrm{Z}=0.3$. Age is on x -axis. The labels indicate year classes and grey lines correspond to $\mathrm{Z}=0.3$.

Figure 4.4.7.4. Norwegian spring spawning herring. Age disaggregated abundance indices (billions) from the acoustic survey on the feeding area in the Norwegian Sea in May (survey 5) plotted on a $\log$ scale. The labels indicate year classes and grey lines correspond to $\mathrm{Z}=0.3$.

Figure 4.5.1.1.Estimated exploitation pattern for the years 1988-2018 by the XSAM model fit. All panels shows includes the same data, but shown at different angles to improve visibility at different time periods

Figure 4.5.1.2. Norwegian spring spawning herring. Correlation between estimated parameters in the final XSAM model fit.

Figure 4.5.1.3. Norwegian spring spawning herring. Weights (inverse of variance) of data-input of the final XSAM model fit.

Figure 4.5.1.4. Norwegian spring spawning herring. Standardized residuals type 1 (left) and type 2 (right) (see text) of data-input of the final XSAM model fit.

Figure 4.5.1.5. Norwegian spring spawning herring. Observed vs. predicted values (left column) and qq-plot based on type 1 (middle) and type 2 (right) residuals (see text) based on the final XSAM model fit.

Figure 4.5.1.6. Norwegian spring spawning herring. Profiles of marginal log-likelihood $\mathrm{l}_{\mathrm{M}}$, the catch component $l_{C}$, Fleet 1 component $l_{F 1}$, Fleet 4 component $l_{F 4}$, Fleet 5 component $l_{F 5}$, point estimate of SSB and average $F$ (ages 5-12+) in 2017 over the common scaling factor for variance in data $h$ for the final XSAM fit. The red dots indicate the value of the respective scaling factors for which the log-likelihood is maximized.

Figure 4.5.1.7. Norwegian spring spawning herring. Retrospective XSAM model fits of SSB and weighted average of fishing mortality ages 5-11 for the years 2012-2017.

Figure 4.5.1.8. Norwegian spring spawning herring. Point estimates of Spawning-stock biomass by years 1988-2018 from model (black lines) and by survey indices from Fleet 1 (red) and Fleet 5 (green). Dotted lines are approximate $95 \%$ confidence interval.

Figure 4.5.1.9. Total reported landings 1988-2017, estimated recruitment, weighted average of fishing mortality (ages 5-12) and spawning-stock biomass for the years 1988-2018 based on the final XSAM model fit. The broken lines are approximate $95 \%$ confidence limits.

Figure 4.5.2.1.1. Norwegian spring spawning herring. Q-Q plot from the eight different surveys used in tuning in TASACS. First row starts with survey 1 and the last one in row four is larval survey.

Figure 4.5.2.1.2. Norwegian spring-spawning herring. Residual sum of squares in the surveys separately from TASACS. First row starts with survey 1 and the last one in row four is larval survey.

Figure 4.5.2.1.3. Comparison of SSB time-series from the final assessment from XSAM and exploratory runs from TASACS (following the 2008 benchmark procedure) and TISVPA. $95 \%$ confidence intervals from the XSAM final assessment are shown.

Figure 4.8.1.1. Estimated selection pattern by XSAM; thin grey lines shows annual estimates 19882017, the median value is indicated by the thick grey line, while selected years (estimates for 20142017 and predictions for 2018-2019) are shown in colours as indicated in the legend.

Figure 4.9.1. Norwegian spring spawning herring. Comparisons of spawning stock; weighted fishing mortality $F(5-14)$ and $F(5-11)$; and recruitment at age 0 and age 2 with previous assessments. In 2016 the proportion mature in the years 2006-2011 was changed; recruitment age changed from 0 to 2 and fishing mortality is calculated over ages 5 to 11. In 2018 (WKNSSHREF) the age range for the fishing mortality changed to ages 5-12.

[^0]:    * $95 \%$ confidence interval
    ** compared to sum of national quotas in 2017, not advice for 2017
    *** difference in fourth decimal compared to $F$ status quo
