6 Cod in divisions 7.e–k (eastern English Channel and southern Celtic Seas)

Full analytical assessment

This stock has been benchmarked at WKCELTIC 2020. XSA was replaced by SAM as the assessment model. Time-series of data were updated since 2004 as well as the tuning series. The first ten years of data (1970–1979) were removed from the assessment time-series of catches, because of inconsistency in cohort tracking information. Data, assessment and forecast procedure are detailed in the stock annex.

Latest ICES advices in 2020 and 2021

2020 – “For Cod in divisions 7.e–k, ICES advises that when the MSY approach is applied, there should be zero catch in 2021.”

2021 – “For Cod in divisions 7.e–k, ICES advises that when the MSY approach and precautionary considerations are applied, there should be zero catch in 2022.”

6.1 General

6.2 Stock description and management units

The TAC is set for ICES areas 7.b–c, 7.e–k, 8, 10, and CECAF 34.1.1(1), excluding 7.d. This is representative of the stock area as the cod population in 7.d is more relevant to the North Sea population. However, landings from 7.bc are not included in the assessment area.

Management applicable in 2021 and 2022

TAC 2021 (Council regulation 2021/1239)

Species:	Cod <i>Gadus morhua</i>	Zone:	7b, 7c, 7e-k, 8, 9 and 10; Union waters of CECAF 34.1.1 (COD/7XAD34)
Belgium	18 ⁽¹⁾	Analytical TAC	
France	290 ⁽¹⁾	Article 9 of this Regulation applies	
Ireland	422 ⁽¹⁾	Article 3 of Regulation (EC) No 847/96 shall not apply	
The Netherlands	0 ⁽¹⁾	Article 4 of Regulation (EC) No 847/96 shall not apply	
Union	730 ⁽¹⁾		
United Kingdom	75 ⁽¹⁾		
TAC	805 ⁽¹⁾		
⁽¹⁾ Exclusively for by-catches of cod in fisheries for other species. No directed fisheries for cod are permitted under this quota.			

Preliminary TAC 2022 (Council regulation 2022/109)

Species:	Cod <i>Gadus morhua</i>	Zone:	7b, 7c, 7e-k, 8, 9 and 10; Union waters of CECAF 34.1.1 (COD/7XAD34)
Belgium	28 ⁽¹⁾	Analytical TAC	
France	463 ⁽¹⁾	Article 9 of this Regulation applies	
Ireland	92 ⁽¹⁾	Article 3 of Regulation (EC) No 847/96 shall not apply	
Netherlands	0 ⁽¹⁾	Article 4 of Regulation (EC) No 847/96 shall not apply	
Union	583 ⁽¹⁾		
United Kingdom	61 ⁽¹⁾		
TAC	644 ⁽¹⁾		
⁽¹⁾ Exclusively for by-catches of cod in fisheries for other species. No directed fisheries for cod are permitted under this quota.			

Since 2005, ICES rectangles 30E4, 31E4, and 32E3 have been closed during the first quarter (Council Regulations 27/2005, 51/2006, and 41/2007, 40/2008, and 43/2009).

Technical measures applied to this stock are a minimum mesh size (MMS) for beam and otter trawlers in Subarea 7 and a minimum landing size (MLS) of 35 cm.

Fishery

Landings data used by the WG are summarised in Table 6.1 and the Figure 6.1 provides historical landings by countries. In 2021, the catches are 1360 t.

TAC was overtaken in 2021. An overtaking of the agreed TAC was observed for France, while Belgium, Ireland and UK were closed to the TAC. Cod is no longer a target species but a bycatch in haddock and whiting dedicated fisheries.

Given the rapid growth of cod in this area, discards are mostly composed of one and two year-old fish. Since 2011, quotas were not restricted and the discard rate has been stable around 10–15%. However, following the recent TAC reductions, TAC is now restrictive for most of the countries. Discards estimate for 2021 is 733 t. It corresponds to a discards rate of 54%, which is significantly greater than the average discards rate of recent years (around 20%). This discards rate increase may be the result of high grading, because of restrictive TACs and delay in total TAC attribution. This delay was mainly due to long discussions in Brexit fisheries negotiations.

Cod is mainly caught in area 27.7.g, followed by areas 27.7.h, 27.7.e and 27.7.j respectively. No landings are reported in 27.7.k and few in 27.7.j2 (Figure 6.2). France is fishing in all areas but most of its landings are taking in 27.7.h. Ireland is mainly fishing in 27.7.g and Belgium in 27.7.f and UK in 27.7.e. For each country, landings distribution in the Celtic Sea is similar to previous years.

In Celtic Sea, cod is mainly caught by OTB_DEF_100-119_0_0_all métiers (37% of the landings and 75% of the catches), followed by OTB_DEF_70-99_0_0_all, OTB_CRU_100-119_0_0_all and seine SCC_DEF_100-119_0_0_all. Beamers (i.e. TBB_DEF_70-99_0_0_all) also contribute to cod landings (Figure 6.3).

Discards rate in weight varies among métiers depending on gear, mesh size range and targeted species (Figure 6.4).

The group advises to follow métier definition specified in the Appendix 2 of the ICES data call to reduce the number of métier upload in InterCatch. Métier which contribute to less than 1% of the landings should be included in the MIS_MIS_0_0_0_HC métier.

Information from the industry

In recent years, yields have been very low and cod is no longer targeted by French vessels and catches represent a very low number of individuals per tow.

The recent regulatory changes in the Celtic Sea since 2019 (Reg UE 2034/2018 which introduces many new selective devices since 01/07/2019 and article 13 Reg UE 123/2020) significantly modifies (1) the size structure of species catches by improving selectivity and the (2) vessel strategy in order to respect different catch composition thresholds.

6.3 Data

InterCatch procedure

Since 2013, international landings and discards data are uploaded in InterCatch. An updated data tile series, from 2004 to 2019, was provided as part of the WKCELTIC 2020. Discards are raised for unreported strata to estimate total discards in weight. During WKCELTIC efforts were made to streamline data compilation procedures for fishery-dependent data of the three main gadoids species (cod, haddock and whiting).

Unsampled strata of landings and discards (number-at-age) are filled in using an allocation procedure. Information on national and international assumptions made by data providers and submitters at the national level and allocation grouping used in IC are available on SharePoint (R script). To ensure the consistency of data processing at international level, the same rules are applied each year for the allocation procedure: fill unsampled strata using as much as possible the same métier and quarter, regardless of area and country. Unsampled BMS landings and Log-book Registered Discards are filled in using discards data employing as much as possible the same métier and quarter, regardless of area and country.

The impact of the Covid-19 pandemic on the fishery cannot be quantitatively determined but may be assumed to have reduced fishing effort in quarter 2 of 2020.

The percentage of sampled versus raised data as well as the distribution of sampled data over the quarters were considered satisfactory (Figure 6.5).

Season	Source	%
1	Imported	23
2	Imported	45
3	Imported	11
4	Imported	19

Catches

Age distribution of 2021 catches (i.e. landings and discards) is illustrated in the Figure 6.10 and Table 6.2. It is noticeable that this stock has always been composed of few age classes, even though Celtic Sea cod can live up to ten years. While the catch was mainly composed of age 2 over the period 2005–2008, the strong 2009 year class has contributed strongly to the catch at older ages in recent years: 63% in number in 2012 at age 3, 36% at age 4 in 2013 (Table 8.2.a and 8.2.b). In 2014, high recruitment has been observed resulting in an increasing proportion of age 1 fish in the landings (53%), age 2 accounts for 22% of the landings. In 2015, landings are dominated by fish of age 2, in 2016 landings are dominated by fish of age 3 and in 2017 landings was mostly composed by cod of age 2. In 2018, 20% of the landings was fish of age 1, 35% of fish of age 2 and 31% of fish of age 3. In 2019, more than 50% of the catches are age 1 fish, and less than 30% of the catches are made of age superior to 2. In 2020, 36% of the catches are age 1 fish, and 58% of the catches (in number) are made of age 2. In 2021, age 1 and age2 represent each 40 % of the catches (in number).

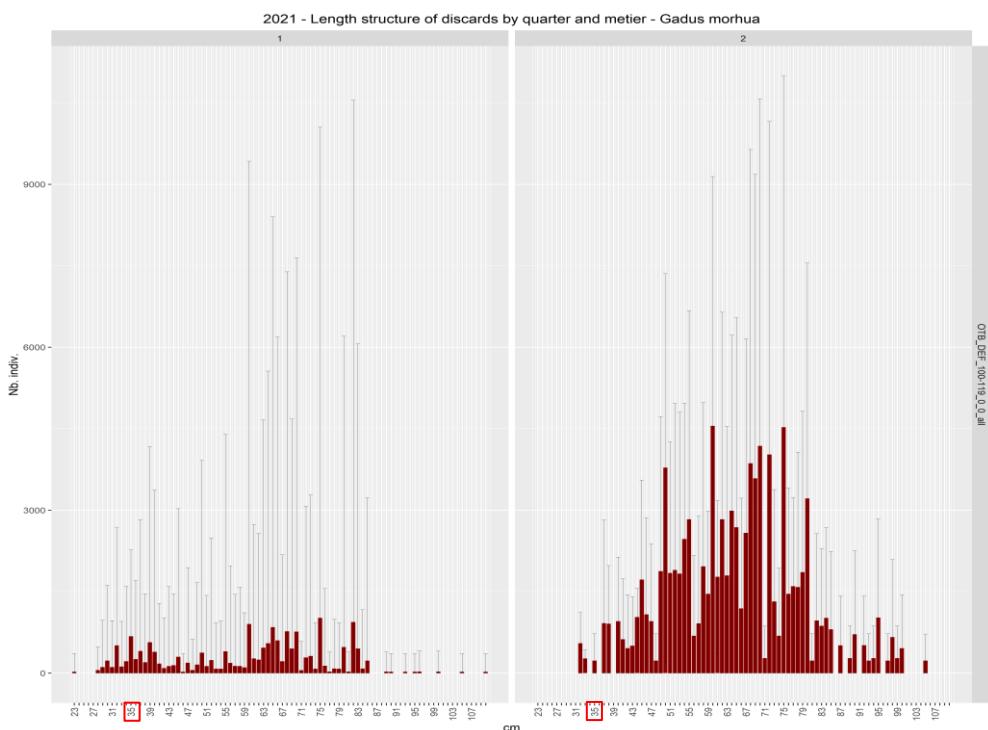

Discards

The landings/discards pattern is known to be strongly variable between fleets and years due to métier, recruitment intensity, TACs constraints and mixed fisheries concerns.

In 2009, age 1 individuals (30–45 cm, Mahé *et al.*, 2016) were mainly discarded. In 2010, most of them were landed. In 2011, ages 1 and 2 represents respectively 51% and 46% of the total discards in numbers for all fleets. Due to the low TAC relative to the high magnitude of recruitment in 2009 and 2010, all countries had unusually high discard rates in 2011, generally 70% by weight was made up of fish above the minimum landing size (MLS, i.e. 35 cm for Celtic Sea cod). The high-graded fish from the French fishery have been added to the landings in 2003–2011. In 2014, total amount of discards was 740 t (639 t imported + 101 t raised), giving a discard rate of 19%. This discards rate was higher than the average 10% and mostly consisted of undersized fish from the strong 2013 year class (fish of age 1 in 2014). In 2015, the total amount of discard was 565 t (250 t sampled and uploaded in InterCatch and 309 t resulting from the raising procedures), giving a discard rate by weight of 12%, which is considered the usual discard rate for this species in the mixed fisheries. High grading in 2015 (discards of fish above Minimum conservation size) was low. In 2016, the total amount of discards was 220 t (154 t sampled and uploaded in Inter-Catch and 52 t resulting from the raising procedures), giving a discard rate by weight of 6.3%. In 2017, the total amount of discards was 117 t (47 t sampled and uploaded in InterCatch and 62 t resulting from the raising procedures), giving a discard rate by weight of 5%, which is considered lower than average. They are mainly composed of age 1 fish (Figure 6.10).

In recent years, due to quota constraints at vessels levels, length distribution of discards for the UK fleet have shown high-grading pattern (cod being a non-target species). However, this fleet has little contribution to both, landings and discards quantities and this was no more reported in 2017. In 2019, discards are mostly composed of fish of 1 year, as in 2018 (Figure 6.10).

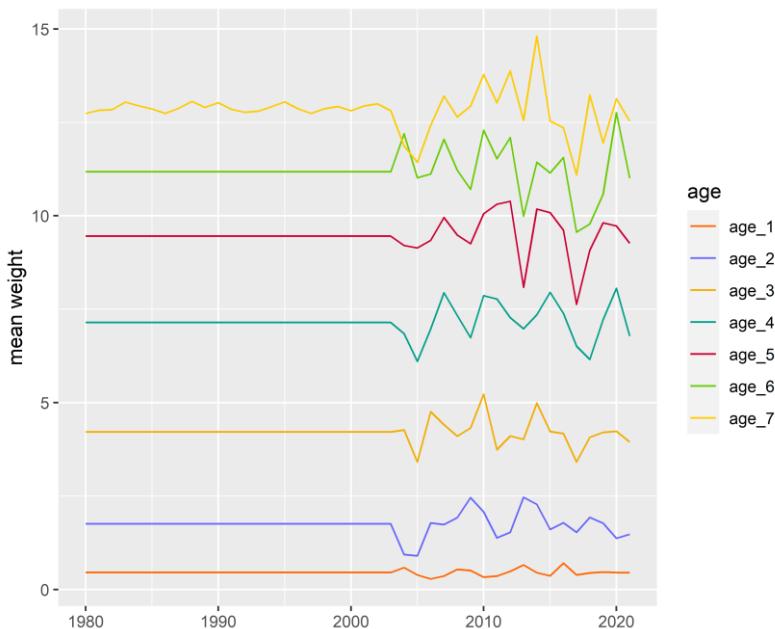

In 2021, French fleet have recorded high-grading pattern for its discards, maybe due to restrictive TACs and delay in total TAC attribution. Individual TAC allocations were attributed in three times and the entire individual TAC was allocated in June. The two preliminary individual TAC, allocated for the period between January and March and between March and July, were reached before the end of their corresponding periods which have led to discard high grading in Q1 and 2.

Biological

Catch numbers-at-age, catch weights-at-age and stock weights-at-age are given respectively in Tables 6.2, 6.3 and 6.4.

Temporal trends in stock and catch were scrutinized at WGCSE 2021, to ensure that reduce sampling due to Covid-19 pandemic did not impact catch weight. No important issues were reported.

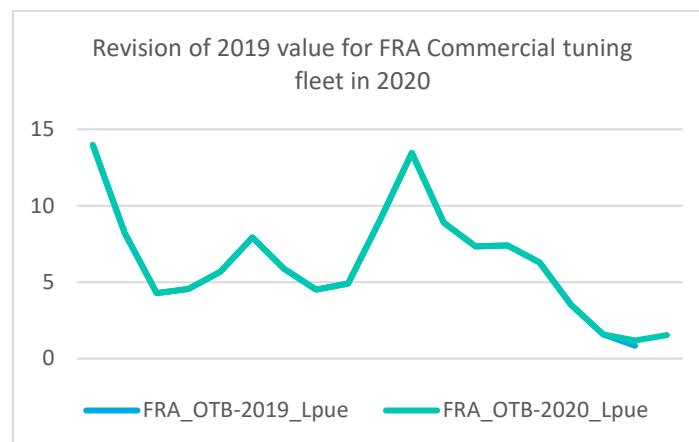

Biological parameters are described in the stock annex which has been updated at WKCELTIC 2020. Celtic Sea cod are very fast growing and early maturing compared with more northern cod stocks.

Commercial LPUE

Tables 6.5 a–c gather the values of landings, fishing effort and LPUE dataseries for the French (a), Irish (b) and UK fleets (c). Figures 6.6 a–c illustrate the trends of LPUE and effort by country.

A general decrease in the LPUE trend is observed in almost all series between 1990 and 2004, where the TAC began to be constraining. From that point, the LPUE seemed to stabilize, or even to increase if high grading is taken into account. The strong 2009 year class resulted in an increase of LPUE for all fleets between 2010 and 2012. Different features are observed in the effort time-series. The métiers showing the highest levels of cod directed effort have decreased significantly in the last 5–10 years until 2010. Since then, effort has gone up again until 2013 following the increased of TAC possibilities.

Since 2013, French fishing effort and LPUE have decreased (Figure 6.6a). Effort of Irish fleet targeting gadoids (i.e. Otter trawl 27.7.g) remains at a high level as a consequence of mixed-fisheries interaction with increased whiting and haddock fisheries opportunities (Figure 6.6b). In the meantime, the Spawning–Stock Biomass (SSB) is low, as such LPUE is decreasing since 2013. In 2018, Otter trawl Irish 27.7.g LPUE has increased. Effort of the UK trawl fleet in 27.7.e–k shows a decreasing trend (down to zero in 2016) and increases since then, while beam trawl effort in 27.7.e–k relatively stable in recent years (Figure 6.6c). Minor revision of FRA commercial fleet from 0.84 to 1.18 in 2019 was made, which is believed to have very little impact on assessment results.

The impact of the Covid-19 pandemic on the fishery cannot be quantitatively determined, but a slight reduction of fishing effort of the main fleets in 2020 was observed for all country. As, a result in 2020, LPUE of Irish otter trawls in 7g and UK trawls in 7ek are decreasing, while French otter trawl LPUE remain stable.

Remark: The UK English and Welsh effort data are only reliable for vessels over 12 metres registered length, and therefore has always been provided to working groups for vessels greater than 12 metres. The fleet of vessels over 12 meter has been declining gradually over the years, until in 2016 no effort recorded from this fleet. The zero figures provided for 2016 have been checked and are correct (Figure 6.6c).

Surveys and commercial tuning fleet

Two ongoing surveys, both part of the DCF, IBTS Q4 (EVHOE-WIBTS-Q4; IGFS-WIBTS-Q4) are combined and modelled to produce a single index using VAST modelling (see details in the stock annex and WKCELTIC 2020 report).

In 2017 and 2018, the French EVHOE survey was not conducted due to technical difficulties at the beginning of the survey. The Irish survey covered additional stations normally undertaken by the EVHOE survey.

Commercial tuning index based on French OTB and OTT fleet is provided. The calculation of the commercial tuning series was updated at WKCELTIC 2020 to better account for changes in fleet behaviour along the years (see details in the stock annex and WKCELTIC 2020 report). LPUE is decreasing since 2012.

The historical time-series of commercial tuning index (OTDEF French fleet for quarters 2, 3 and 4), and the survey index are shown in Table 6.6.

Data issues

No important issues were reported this year. Owing to notable divergence of recent discards patterns, it was not possible to forecast separate landings and discards estimates for 2023.

Catch sampling of the fisheries has been reduced in 2020 due to Covid-19, which may have result in a higher uncertainty associated with discard estimates and age structure of the catch. However, this was considered to have had minimal impact on the perception of the stock status.

Remark: When for a métier/strata landings are upload annually, there are no information available in InterCatch to split the annual landings into quarterly landings and therefore the associated age composition and mean weight-at-age. As a result, when extracting quarter 1 versus

quarters 2, 3 and, 4 data to inform on mean weight of the stock and the catch for the assessment, these data are not used.

6.4 Stock assessment

Model used: SAM (stockassessment.org).

Final update assessment (SAM)

The final assessment was run with the same settings as established by WKCELTIC 2020 and described in the stock annex. Discards are included in the assessment. (sotcokassessment.org/Cod_7ek_WGCSE2020).

Residuals and diagnostics do not highlight any problem regarding the input data and model fit (Figure 6.7 and 6.8). Outputs from the assessment are reported in Tables 6.7–6.10 and in Figures 6.7–6.11.

The comparison of runs with and without tuning indices indicates is shown in Figure 6.12b. The information contains in both indices are consistent.

In 2022, the assessment shows a downward revision in F (Figure 6.12a). The estimate of fishing mortality is highly sensitive to the additional annual data, this is due to the low stock size.

Mohn's rho analysis (i.e. a measure of the relative difference between an estimate from an assessment with a truncated time-series and an estimate of the same quantity from an assessment using the full time-series) resulted in values of -12% for $F_{\bar{S}2-5}$, 23% for SSB and 40% for recruitment.

The retrospective bias in assessment when an additional year of data are incorporated may be due to the variability of cod recruitment over years, the strong dependency of the fishery to recruitment (not well estimated by the survey) and the unexpected disappearance of fish of older age.

Despite the high values of the Mohn's rho coefficient and the uncertainties in the estimates of the most recent year, the assessment has been validated (the stock is maintained in category 1), and the output are used to provide the short-term forecast. This decision follows the guidelines provide by WGBIAS (decision tree). Despite the uncertainties in the estimates of the most recent years, SSB and F are estimated well below biological references points.

The conclusions of the very recent benchmark was that given the recruitment driven dynamics of the stock and the low stock size reducing.

State of the stock

Tables 6.7 and 6.8 summarise the estimated fishing mortality-at-age and the stock numbers-at-age, respectively. The stock summary is reported in Table 6.9 and Figure 6.11.

Catches were around 5000 t between 2000 and 2016, with some higher catches following strong recruitments, and decreased around 1300 t since 2019 (Figure 6.11). Reliable discard estimates are available since 2004 and range between 134 and 3749 t depending on the interplay between recruitment dynamics and TAC constraints.

Recruitment has been highly variable over time with occasional very high recruitment followed by period of low recruitments. Since 2012, recruitment has been very weak with the exception of the 2014 year class, which is above average (Table 6.9 and Figure 6.11).

Spawning-stock biomass (SSB) has been fluctuating around B_{pa} since 2004, except from 2011 to 2013 (as the consequence of a very good recruitment year) and is below B_{lim} since 2017 (Table 6.9 and Figure 6.11, ICES, 2012).

Fishing mortality has been above F_{MSY} for the entire time-series, fluctuating between F_{lim} and F_{pa} . Fishing mortality increased up to above F_{lim} between 2017 and 2019 (Table 6.9 and Figure 6.11).

6.5 Short-term projections

Assumptions made for the short-term projections are described in Table 6.12 and followed the stock annex.

F status quo was used as an assumption of F in 2021 to reflect recent fishing pressure and was kept for 2022.

Recruitment values of 2022 and 2023 are similar in the stochastic forecast, because random resampling of a distribution may lead to identical median estimates. The recruitment age 1 fish values are 1305 thousands in 2022 and 2023.

SSB is predicted to be 992 t in 2023 which would still be below B_{lim} (4200 t) (Table 6.11).

ICES provides zero-catch advice for this stock in 2023, because the median SSB remains below B_{lim} by 2023 under all catch scenarios (Tables 6.12 and 6.13).

In the ICES advice framework, this would result in advised catches between 46 tonnes (at $F_{MSY} \times SSB_{2023}/MSY B_{trigger}$) and 77 tonnes (at $F_{MSY} \times SSB_{2023}/MSY B_{trigger}$), but the median SSB would remain below B_{lim} by 2024.

The assumed recruitment in 2022 and 2023 used in the forecast constitutes a significant part (70%) of the projected SSB in 2024 (45% and 25%, respectively; Figure 6.14 and Table 6.14).

6.6 Medium-term projection

No medium-term projections were carried out.

6.7 Biological reference points

The reference points have been estimated using the agreed ICES guidelines, see Table 6.11 (ICES, 2016). F_{pa} was set to $F_{p0.5}$; the F that leads to $SSB \geq B_{lim}$ with 95% probability at the last benchmark in 2020.

6.8 Management plans

The European Parliament and the Council have published a multiannual management plan (MAP) for the Western Waters (EU, 2019). This plan applies to demersal stocks including cod in ICES divisions 7.e–k.

6.9 Uncertainties and bias in assessment and forecast

The stock was benchmarked in 2020 (ICES, 2020a). The model was changed to a stochastic state-space assessment model (SAM). Maturity and natural mortality information was updated, discards were included in the assessment, catch (landings and discards) time-series were reviewed and updated from 2004 to 2018, commercial tuning series were reviewed and included as

biomass index, and survey indices were updated to a single modelled time-series using a vector-autoregressive spatio-temporal model (VAST). The F-pattern shows less variability across the time-series and higher estimates in most recent years than the previous assessment. Fishing mortality is observed to be sensitive to the addition of an extra year of data.

However, despite this uncertainty, it is quite clear that the cod stock is well below SBB limits and well above F target. Given that situation and the recommendations of WKBIAS, the last benchmark and WGCSE 2022 validated the proposed assessment model and its use for prediction.

6.10 Recommendations for future developments

There is room for development of a modelled commercial tuning fleet instead of the current method based on catch thresholds. Indeed, despite the work performed to improve the commercial tuning fleet, it is never easy to account for changes in fisheries targeting behaviours. Indeed, in recent years, cod is not targeted anymore by most of the fisheries.

Even if the survey index combined two surveys, it is based on few fish. Further work and sensitivity analysis on the VAST assumptions might also be performed and documented in the future to ensure that the model will converge for all ages and show low retrospective patterns.

6.11 Management considerations

The strong retrospective pattern implies that the current F estimates might be uncertain. Forecasts are sensitive to the assumption on recruitment as the landings are usually composed of a high proportion of age 2 fish (and age 1 for discards).

The recent technical measures introduced in the Celtic Sea, increase in the mesh size of the square mesh panels and raised lines are expected to reduce catches of Celtic Sea cod and improved the selection pattern. Impact of this measure should be monitored.

Additionally, mixed-fisheries issues could be responsible for maintaining F at high level, as other gadoids fishing opportunities are higher. In this context, cod is no longer a target species but can be considered as bycatch in the fleet targeting haddock, whiting and *Nephrops*.

Historical information on management consideration can be found in the stock annex.

base	-209.68	14	447.37

Table 6.11. Cod Division 7e–k. Short-term forecast assumption.

Variable	Value	Notes
F ages 2–5 (2022)	1.139	$F_{sq} = F_{average}$ (2019–2021)
SSB (2023)	992	Fishing at F_{sq} , in tonnes.
Recruitment age 1 (2022–2023)	1305,1305	Median from resampled (2015–2021); in thousands
Total catch (2022)	1220	Fishing at F_{sq} , in tonnes.

Table 6.12. Cod in Division 7e–k. Reference points.

Framework	Reference point	Value	Technical basis	Source
MSY approach	$B_{trigger}$	5800	B_{pa} ; in tonnes	ICES (2020a)
	F_{MSY}	0.29	Segmented regression with B_{lim} (EqSim)	ICES (2020a)
Precautionary approach	B_{lim}	4200	B_{loss} , lowest observed SSB from which there has been some recovery (2005) rounded value; in tonnes	ICES (2020a)
	B_{pa}	5800	$B_{lim} \times 1.4$; in tonnes	ICES (2020a)
Management plan	F_{lim}	1.13	Segmented regression with B_{lim} (EqSim)	ICES (2020a)
	F_{pa}	0.77	$F_{po.5}$; the F that leads to $SSB \geq B_{lim}$ with 95% probability	ICES (2020a)
Management plan	MAP MSY $B_{trigger}$	5800	MSY $B_{trigger}$; in tonnes	EU (2019), ICES (2020a)
	MAP B_{lim}	4200	B_{lim} ; in tonnes	EU (2019), ICES (2020a)
Management plan	MAP F_{MSY}	0.29	F_{MSY}	EU (2019), ICES (2020a)
	MAP range F_{lower}	0.17	Consistent with ranges resulting in no more than 5% reduction in long-term yield compared with MSY	EU (2019), ICES (2020a)
Management plan	MAP range F_{upper}	0.41	Consistent with ranges resulting in no more than 5% reduction in long-term yield compared with MSY	EU (2019), ICES (2020a)
